Captain Mahan says that the ligature had been "awkwardly" applied. I suppose that even a surgeon need not take exception to his use of this adverb, for though its first meaning is "clumsily," it may simply mean "unfortunately." Nelson, however, did not say that the artery was "awkwardly" secured. He was too loyal a patient to use such a word, and I do not believe that he ever thought it. He alluded to the inclusion of the nerve as an "unlucky circumstance," and when writing to his wife he said, "I am fortunate in having a good surgeon on board." Certainly no surgeon would use the word "awkwardly" in connexion with the accident; it would be ungenerous and would suggest lack of dexterity on the part of the operator. Indeed, as we look back upon that sorrowful early morning after the glorious failure at Teneriffe the surgeon of the *Theseus* receives a fair share of our kindly sympathy. He had no friendly help from ether or chloroform, and his patient was weak from loss of blood—not another drop must be lost. To-day he would be prepared to supply such deficiency by the injection of a pint or more of hot salt water into a large vein. The amputation had to be done at lightning speed; as we know, the sea was rough, and we can imagine the scanty illumination below decks. Indeed, not only the field of operation, but the entire ship must have been shrouded in gloom and depression.

Returning to England Nelson joined Lady Nelson at Bath, where he continued to be the subject of "much pain and some fever." For the ligature still held to the nerve, and the granulation-tissue lining the two-inch sinus was continuously absorbing small doses of the septic discharge. This auto-intoxication could not fail to make him ill and unhappy, and it probably caused him to be the subject of headaches, thirst, perspirations, and shiverings. Probably, also, this association of symptoms constituted the evidence of the "fever" to which he alludes. Or, as there was no clinical thermometer in those days, the presence of fever may have been recognised by the mere application of the surgeon's hand to the surface of the patient's body—an extremely fallacious method of examination.

A consultation was held in England as to whether the nerve could not be freed of the lingering ligature; but we learn that the surgeons were afraid to cut blindly into the depths of the sinus lest they should at the same time wound the artery with the scissors. So no interference was undertaken, and our hero was left to suffer. In similar circumstances, at the present time, the wound would be promptly and deliberately opened up and the removal of the ligature safely effected. But a hundred years ago surgeons were in constant dread of secondary hæmorrhage from operation wounds—a contingency which aseptic surgery has practically abolished from our midst. They would not have dared to separate the adhering flaps of the stump lest, so doing, they might be courting disaster.

Whether in hospital work or in private practice soldiers and sailors make the best of patients. They give a willing obedience to all instructions and they take things as they come, without question or complaint. Here was Nelson on Oct. 2nd, 1797, in constant distress because a large nerve was by misadventure tied along with the artery, and speaking of its inclusion as an "unfortunate circumstance." *O si sic omnes.*

Southey says that the first letter that Nelson wrote with his left hand was to Lord St. Vincent. It is not improbable that this is an error, as he appears to have written a very early one to the bride of his friend, Captain Thomas Freemantle, who, like Nelson, had been shot in the arm in the attack upon Santa Cruz. I have not the date of that letter; it runs thus:—

> "MY DEAR MRS. FREEMANTLE,—Tell me how Tom is; I hope he has saved his arm. *Mine is off*, but, thank God, I am as well as I hope he is.
>
> "Ever yours,
>
> "HORATIO NELSON."

The letter above produced in *facsimile*, being dated Oct. 2nd, 1797, was written within ten weeks of the amputation of Nelson's right arm, and it has the great merit of being perfectly legible. I have professional friends who cannot write half as clearly as this with either hand, and as to the hurried handwritings in papers which one has to decipher in the course of a certain examination, many would be discreditable to boys from the fifth standard of a Board school. But our profession has not the monopoly in bad writers. It would be an interesting, and probably a valuable,

No. 141, Bond Street,
Oct. 2d, 1797.

My Dear Sir.

I am much obliged by your kind enquiries, My Arm from the unlucky circumstance of a Nerve being taken up with the Artery is not yet healed nor do I see any prospect of the ligatures soon coming away

Horatio Nelson

experiment, if all bad writers were compelled to educate their left hand in the use of the pen; this might have the advantage of making their communications precise as well as clear. I cannot but think that in the case of some writers the cells upon the wrong side of the brain have been forced to specialise in the graphic function, and that a little practice with the other hand might afford a cellular group in the other cerebral hemisphere the opportunity of taking up their neglected but proper office. In my opinion, too narrow a specialism of the cells of the left motor area is undesirable, the individual using his right hand for all the finer acts. For my own part, I like to see a child indiscriminately putting out his left hand to greet a friend, or holding his knife or scissors in it. But so surely as he does it some relative or nurse calls out, "The other hand, dear." A very considerable proportion of our best bowlers are left-handed; fortunately there was no Mrs. Grundy in the playground or cricket-field to interfere with the course of Nature and to render their movements artificial. In some cases the motor areas upon the two sides of the cricketer's brain have established a sort of compromise, and so we see the man bowling with his left hand and batting with his right. I think that every man who intends to use a razor should learn to shave with his left hand as well as with his right; he cannot say but that the lesson once learnt may some day be of the greatest use to him.

GUY'S HOSPITAL.

A CASE OF GONORRHŒA WITH EXTENSIVE SUPPURATION; URINARY AND FÆCAL EXTRAVASATION.

(Under the care of Mr. CLEMENT LUCAS.)

THE number of complications that may accompany an attack of gonorrhœa is very large, and the following case is a noteworthy instance of the very widespread suppuration that may occur in this disease. The noteworthy points are the formation of a sinus above the pubes and the development of the fistula opening into the bowel. For the notes of the case we are indebted to Mr. C. H. Fagge, house surgeon.

A man, aged twenty-one years, was admitted into Guy's Hospital on March 4th, 1897, complaining of a swelling in the perineum. In November and December, 1896, the patient had suffered from gonorrhœa and was treated privately, and when the discharge stopped about Christmas he noticed that he had much difficulty in micturition, which culminated in complete retention. Catheters were used for five days, and by their means the spasmodic obstruction was overcome, and he has since passed urine freely. About a week after catheterism was abandoned he noticed a swelling in the perineum; it was very tender and painful, and the pain was greatly increased on micturition. Soon after this a swelling formed above the pubes, and he experienced shooting pains passing from the perineum upwards to the front of the abdomen. The swelling above the pubes pointed and was opened, and pus was evacuated. Lately he had noticed that a little urine came away per rectum at the end of micturition, and that flatus escaped from the opening above the pubes, and from this opening urine also sometimes dribbled after micturition. His family history was good, and he had always had good health, excepting an attack of pleuro-pneumonia five years previously. On admission the patient was seen to be pale and somewhat emaciated. In the middle line, three inches above the umbilicus, was the opening of a small sinus, from which a little pus could be expressed; the skin surrounding the opening was brown, indurated, and tender. In the perineum was an oval, lax, fluctuating swelling extending from the back of the scrotum to the anterior margin of the anus. On pressing this swelling flatus escaped through the sinus in front. In the globus major of the right epididymis was a hard nodule about the size of a cherry stone. The urine was acid and contained a trace of albumin; small quantities of blood and pus were also present. On March 5th Mr. Lucas made a rectal examination and found on the anterior wall of the bowel an opening with tender swollen edges, situated about three-quarters of an inch from the anus. An anæsthetic (A.C.E.) having been given, a probe was inserted into the sinus in front, and it was found to pass downwards. This sinus was slit up as far as the pubes and was thoroughly irrigated. The patient was then put in the lithotomy position, and the fluctuating perineal swelling was laid open from scrotum to anus, the sphincter, however, not being divided. A probe was then introduced and was found to enter the rectum through the opening already mentioned; a little pus was washed out and the cavity packed with iodoform gauze, and over this an antiseptic dressing was applied. On March 8th the packing was taken out of the perineal wound and was found to be saturated with fæcal matter, which was also present in the wound. The patient complained of much pain, which was increased by movement and by micturition. On March 11th he said that he felt better and stronger; there was less pain; micturition, which occurred every four hours, was, however, painful. By March 12th the wound above the pubes had contracted, leaving a healthy granulating surface measuring about three inches by two and a half inches. The perineal wound did not look so healthy, and a small quantity of urine appeared to come through the sinus occasionally. He now had some constipation, and though after purgatives the bowels were opened a small quantity of blood was passed with the motions. From the perineal opening urine continued to flow occasionally. On March 20th the patient strained greatly at stool, but was unable to pass any motion. As a result of the straining the perineal wound opened more, with slight bleeding; the suprapubic wound still extended upwards two inches from the pubes, but it was doubtful if it communicated with the perineal wound. Both the wounds were syringed with a solution of perchloride of mercury and were then filled with iodoform gauze. On March 22nd the temperature in the evening was 102 4° F., and later there was some sweating, this being apparently due to septic absorption. The evening rise and morning fall of the temperature continued until April 1st, when the patient felt better. An anæsthetic was given, the perineal wound was more freely opened and thoroughly scraped out, a blunt director was passed from the perineal wound into the rectum, and the intervening tissues were divided. Iodoform powder and gauze and an antiseptic dressing were applied. This dressing was continued daily and the wounds steadily became smaller, and by May 29th the suprapubic wound was almost healed. A No. 9 coudé catheter was passed, and a few days later a No. 10. On June 4th the wounds had both nearly healed and the patient was ready to leave the hospital.

EDINBURGH ROYAL INFIRMARY.

PROGRESSIVE PERNICIOUS ANÆMIA OF UNUSUALLY RAPID DEVELOPMENT, ASSOCIATED WITH MARKED JAUNDICE, ETC.; RAPID RECOVERY UNDER LARGE DOSES OF ARSENIC.

(Under the care of Dr. BYROM BRAMWELL.)

TO Addison is undoubtedly due the credit of first recognising "idiopathic" or "pernicious" anæmia as a definite disease, though it has been customary to associate the name of Biermer, of Zurich, with the discovery. At the present time we are hardly nearer a knowledge of the cause of this disease than when it was first described, but it may be taken as extremely probable that a toxin is the immediate cause, and the results obtained by Dr. William Hunter by the injection of tolylene-diamine point strongly in the same direction. Dr. Byrom Bramwell must be credited with the introduction of arsenic in the treatment of pernicious anæmia, and in some cases it certainly effects a cure, but in others its administration seems to be without any benefit.

A man, aged fifty-three years, was admitted to the Edinburgh Royal Infirmary on May 3rd, 1897, complaining of great general weakness and jaundice. The patient stated that three months previously he began to feel a little sick after taking food, but that until six weeks ago he was out with shooting parties every day and was able to do his regular work, which involved much hard

Digitized by Google

hill-climbing, without difficulty. On March 10th he noticed that his skin was yellower than it used to be and that the urine was dark in colour. About the same time he experienced some pain in the upper part of the abdomen, and became so weak that he had to give up work. The weakness and jaundice steadily progressed, and he got thinner. He also suffered from headache and constipation. Latterly his sight became somewhat dim. During the last three weeks he got rapidly worse and vomited occasionally. Up to the commencement of this illness he was a very robust and healthy man; indeed, with the exception of an attack of influenza two and a half years ago, from which he perfectly recovered, he had never been ill. He had always been very temperate with regard to alcohol. He knew of no cause for the present illness. As regards his family history, his parents were long-lived. He had had four children; two died from diabetes at the ages of seventeen and twelve years respectively; the other two were quite healthy. On admission the patient's chief complaint was extreme debility. He was deeply jaundiced and at the same time profoundly anæmic. Instead of the delicate lemon-yellow hue characteristic of pernicious anæmia the colour of the skin resembled that of a ripe banana. The muscles were somewhat wasted and flabby, and there was little fat on the surface of the body. There was some œdema of the feet. The patient's weight was 12 st. 2 lb., and his height 6 ft.; his normal weight was 12 st. 6 lb. On the evening of admission the temperature was 100°F. The patient stated that he was very short of breath on exertion, and that he was giddy when he stooped or suddenly rose from the recumbent to the erect position. The heart did not appear to be enlarged; the cardiac impulse and sounds were very feeble; there were no cardiac murmurs. A well-marked venous hum was present in the neck. The radial pulse, which numbered ninety-six per minute, was small in volume and of low tension. The condition of the blood was highly characteristic of pernicious anæmia. The red blood corpuscles numbered 810,000; the hæmoglobin equalled 20 per cent. On microscopical examination the red corpuscles did not go into rouleaux. Many of them were larger and many of them were smaller than normal. Most of them were irregular in shape. Many of the red corpuscles appeared to be nucleated in consequence of the hæmoglobin being concentrated at one point of the corpuscle; but after staining with various reagents no true nucleated red corpuscles could be seen. Some small deeply pigmented corpuscles (Eichhorst's corpuscles) were present. The leucocytes were not increased in number. The blood plates appeared to be normal. The blood did not seem to contain any organisms. Dr. Robert Muir made and incubated several cultivations, but with negative results. Many minute hæmorrhages were seen in both retinæ; some radiated in striated lines round the discs, others more punctiform in shape were scattered over the retinæ, for the most part in the course of the vessels. There was no optic neuritis. The respiratory system was normal. The appetite was very poor and the tongue was thickly furred. The patient stated that he often felt sick, but rarely vomited. The bowels were constipated. The stools were of a bright orange (burnt sienna) colour. No parasitic organisms could be detected in the stools on microscopic examination. There was some tenderness over the lower margin of the liver, which extended for one and a half inches at least below the margin of the ribs. The upper margin of the liver, as determined by percussion, corresponded to the upper border of the fourth rib. The spleen appeared to be of normal size. The urine was normal in amount, dark amber coloured (much less dark than might have been expected from the acuteness of the anæmia and the intensity of the jaundice), acid, its specific gravity 1016; it contained a small amount of albumin and a trace of bile, and on microscopical examination a few hyaline casts. The patient complained of some headache—sometimes frontal and sometimes occipital. He stated that since his illness commenced he had been more sleepy than formerly. The knee-jerks were markedly diminished, but there were no other symptoms suggestive of disease of the cord. The patient was kept in bed, and milk diet and gradually increasing doses of arsenic (Fowler's solution) were prescribed. On May 7th seven drops of Fowler's solution three times daily were prescribed by Dr. Coleman, the house physician (Dr. Bramwell usually begins with a smaller dose), and this dose was increased by three minims daily until the 20th, when the patient was taking the very large quantity of sixty minims. After this the dose was reduced to forty minims per diem. The daily temperatures were as follows:—May 3rd, E. 100° F.; May 4th, M. 98·2°, E. 100°; May 5th, M. 98·6°, E. 99·6°; May 6th, M. 98·0°, E. 99·6°; May 7th, M. 99·0°, E. 99·8°; May 8th, M. 98·6°, E. 97·8°; May 9th, M. 97·4°, E. 98·6°; May 10th, M. 97·4°, E. 97·4°; May 11th, M. 97·6°, E. 98·2°; May 12th, M. 97·8°, E. 98·2°. On and after May 13th the temperature continued normal. The pulse was 96 on May 3rd, 4th, 5th, and 6th; on May 7th and 8th it varied between 96 and 116, but on the succeeding days it declined. The patient's bowels were moved once daily on May 4th, 7th, 8th, 10th, and 11th. On the 6th the urine deposited a large quantity of orange-coloured sand, which consisted of very minute crystals of uric acid. On the 9th the temperature, which since the patient's admission had risen to about 100° each night, was subnormal. Uric acid was still present in considerable quantity in the urine. On the 10th the jaundice was less marked, and the patient stated that he felt less sick and that his appetite was improving. The red blood corpuscles numbered 970,000, and the leucocytes 13,000 per cubic millimetre; the hæmoglobin equalled 28 per cent. The urine continued to deposit a considerable quantity of uric acid. On the 16th the patient was steadily improving and he felt much stronger. The feeling of nausea in the morning, which had been a good deal complained of, was less. The heart's action was more forcible. The stools still had the same yellow ochre colour, and the urine continued to deposit large quantities of uric acid crystals. The lower margin of the liver did not then extend below the margin of the ribs. A marked improvement had taken place in the condition of the blood. The red blood corpuscles now numbered 1,710,000, and they were much more normally shaped; the white corpuscles numbered 12,000 per cubic millimetre; and the hæmoglobin equalled 40 per cent. The patient was taking forty-eight minims of Fowler's solution per diem. On the 18th the patient complained of irritation of the eyes, as if they were filled with sand, and of a feeling of sickness. The urine still contained a small quantity of albumin and a few hyaline casts, but it no longer deposited uric acid crystals. The feet and legs were still œdematous. The amount of arsenic was increased to fifty-four minims daily. By the 20th the dose of arsenic had reached sixty minims per diem. On the 21st a vesicular (herpetic) eruption commenced on the left side of the forehead, and the dose of arsenic was reduced to forty minims per diem. On the 23rd the patient felt much better; he was much less anæmic, the jaundice had almost entirely disappeared, the red corpuscles numbered 2,650,000 per cubic millimetre, and the hæmoglobin equalled 42 per cent. On the 26th, though the feet were still slightly swollen, the patient was rapidly improving and feeling much stronger. The urine was now free from albumin. On the 30th the red corpuscles, which now numbered 2,950,000 per cubic millimetre, were for the most part normal in shape; the hæmoglobin equalled 46 per cent. The urine then contained phosphates, but no albumin. The vesicular (herpetic) eruption which had developed six days previously on the left side of the forehead had almost completely disappeared. The eyes were still "sandy" and the throat was a little dry. On June 8th it was noted that the patient had been up for the past two days. The lips were red and the face was injected. Retinal hæmorrhages were no longer present. The red blood corpuscles, which were for the most part normally shaped, then numbered 2,700,000 per cubic millimetre, and the hæmoglobin equalled 64 per cent. On the 14th the red blood corpuscles numbered 3,420,000 per cubic millimetre, and the hæmoglobin equalled 64 per cent. Some of the red blood corpuscles were still mis-shaped, and a few Eichhorst's corpuscles were still present. One or two large leucocytes containing numerous minute particles of dark brown pigment were seen in the specimen of blood examined on this date. The patient's weight had decreased during the last fortnight. On May 12th he weighed 12 st. 2 lb.; on the 22nd, 12 st. 5 lb.; on the 29th, 12 st. 5 lb.; on June 5th, 12 st. 1 lb.; and on the 12th, 11 st. 12 lb. The urine was free from albumin. Since May 30th the patient had taken forty minims of Fowler's solution daily. On the 15th the patient left the hospital, feeling, he said, perfectly well. He was advised to continue the arsenic in smaller doses (twenty-four drops daily) and to return at once for treatment if a relapse should occur. The remarkable change in his appearance was shown by the following circumstance. Before his discharge he was sent with a note asking Dr. Muir to re-examine the blood. Dr. Muir did not recognise him, and wrote back requesting that the patient should be sent to him for examination. On July 20th the patient reported himself at the infirmary. He looked the picture of ruddy health and stated that he felt quite well. The red

Digitized by Google

corpuscles numbered 4,010,000 per cubic millimetre, the white corpuscles 14,000; the hæmoglobin equalled 88 per cent. (Gowers's instrument); the red corpuscles were normal in shape; no Eichhorst's corpuscles were seen. The patient was advised to go on with the arsenic. The steady improvement in the condition of the blood is shown in the following table:—

Table showing the Condition of the Blood and Dose of Arsenic at Different Dates.

Date.	Number of red blood corpuscles per cubic millimetre.	Percentage of hæmoglobin.	Number of white blood corpuscles per cubic millimetre.	Dose of liquor arsenicalis per diem.
May 5th	810,000	20	—	20 minims.
May 10th	970,000	28	13,000	40 ,,
May 16th	1,710,000	40	12,000	50 ,,

June 14th	3,420,000	64	12,000	40 ,,
July 20th	4,010,000	88	14,000	

Remarks by Dr. BYROM BRAMWELL.—This highly characteristic case of pernicious anæmia presents several points of great interest. The more important are:—1. The rapid development. It is, I think, the most acute case which has come under my own notice. Though some pain in the region of the stomach was experienced at the beginning of January the patient did not feel ill, and no symptoms were observed until six weeks before his admission to hospital. 2. The causelessness of the attack. So far as could be ascertained there was absolutely no cause (intestinal or other) for the disease. 3. The absence of organisms in the blood. The blood contained no organisms. For many years past I have stated in my lectures that some cases of pernicious anæmia are perhaps due to the presence of some form of micro-organism in the blood. This case, in which the symptoms were so profound, the duration so short, and the course so progressive seemed to be a most suitable case for testing this question, and it is important to note that Dr. Muir's observations were attended with negative results. But this by no means proves that in all cases of pernicious anæmia micro-organisms are absent from the blood; for, as I have stated in a recent article,[1] it is not improbable that the condition which we term progressive pernicious anæmia is perhaps a group of clinical symptoms (which may be due to a variety of causes) rather than a single disease—a single clinical entity. It is possible, if this view is correct, that in some cases of pernicious anæmia organisms are present in the blood, while in others they are absent. 4. The presence of Eichhorst's corpuscles in the blood. These small, deeply stained corpuscles are in my experience rare. I have never seen them so numerous as they were in this case. 5. The intensity of the jaundice. I have never met with any case of pernicious anæmia in which the jaundice was anything like so deep as it was in this case; and yet the stools were of a deep orange (yellow ochre) colour and the urine only contained a faint trace of bile. Further, it should be noted that on the patient's admission the liver was enlarged and tender. 6. The colour of the urine. The urine was never very dark—it was dark amber coloured; it was much less deeply pigmented than one might have expected considering the severity of the case, the acuteness of its development, and the intensity of the jaundice. 7. The absence of parasitic organisms in the stools. 8. The presence of albumin and a few hyaline tube casts in the urine. The albumin and casts were merely temporary; but even the temporary presence of albumin is in my experience quite exceptional in cases of pernicious anæmia. The hyaline casts were probably the result of the jaundice. In my experience—and this important clinical fact is not, I think, sufficiently known—hyaline casts are almost invariably (I am disposed to think invariably) present in cases of well-marked jaundice. 9. The copious uric acid deposits in the urine. I have met with one or two other cases of pernicious anæmia in which large quantities of uric acid were deposited in the urine; in one case the patient suffered from recurring attacks of gout. 10. The absence of any degree of cardiac dilatation and of cardiac murmurs. Considering the extreme degree of the anæmia these were remarkable features of the case, and are perhaps explained by the rapidity of the course of the disease and the short time that it had been in existence when the patient came under observation. 11. The large doses of arsenic which were administered (for several days the patient took no less than from fifty to sixty minims of Fowler's solution in the twenty-four hours) and the remarkably rapid recovery which took place both in the condition of the blood and as regards the jaundice and other symptoms under the arsenical treatment. Since I first employed arsenic in the treatment of pernicious anæmia in the year 1875 I have not met with any case in which the results have been more satisfactory than in this case. It is probable, I think, that in this case the acuteness of the disease favoured the success of the treatment. In the advanced stages of severe and long-continued cases, arsenic, and every other plan of treatment often, as might be expected, fail to produce any beneficial effect. 12. The development of a herpetic eruption on the forehead during the arsenical treatment. Mr. Jonathan Hutchinson has directed attention to the fact that herpes zoster is in some cases apparently the result of arsenic. This is of great interest, especially when it is remembered that arsenic is a specific in many cases of recurring herpes of the vulva and in pemphigus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Hæmorrhage into the Broad Ligament.—Double Ovariotomy.—Dermoid Cysts of the Ovary.

A MEETING of this section was held on May 28th, Dr. LOMBE ATTHILL, the President, being in the chair.

Dr. J. H. GLENN being absent the Secretary read the following notes of a case of Hæmorrhage into the Broad Ligament arising from the Stump of an Ovarian Cyst, and Complicating the Puerperium:—In January, 1894, I removed a left ovarian cyst from a young married woman, whose age was stated to be twenty-seven years. The operation was simple, and the only feature of interest was an excessively varicose condition of the pedicle. This gave rise to a little more hæmorrhage than is usual, but was carefully ligatured and the patient went on uninterruptedly. On Jan. 27th, 1895, I delivered her of a living female child by forceps. On Sept. 19th, 1896, I was called again, but the infant was already born on my arrival; this time it was a boy, which is interesting, as she had only the right ovary. The uterus was firmly contracted and no trouble was experienced with the placenta, as it came away easily, neither was there any oozing. On palpation there was nothing now to be detected, but I did not feel satisfied as the patient's pulse was 110 and her aspect anxious. About fifteen minutes after the expulsion of the placenta I felt a swelling on the left side, which corresponded to the height of the firmly contracted uterus, strangely simulated a uterus bicornis, and soon rose almost as high as the lower border of the ribs in the mammary line, but little over the middle abdominal line. I awaited developments, and the patient recovered, her highest temperature being 99·4° F. I believe that here we had a rupture of one of the varicose veins mentioned above as seen in the pedicle. Five months after confinement the hæmatoma had dwindled to the size of a fœtal head and was distinctly fluctuating.—Dr. EMILY WINIFRED DICKSON said that it seemed difficult to her to imagine how the broad ligament could have suddenly become distended so much as to allow the tumour to reach up to the ribs.

Dr. E. WINIFRED DICKSON read a paper on Double Ovariotomy with eighteen months interval between the operations. The patient, aged forty years, was admitted to the Richmond Hospital, Dublin, in May, 1895, suffering from ascites and an abdominal tumour. An ovarian papillary cystoma was removed from the left side, and the patient made an aseptic recovery. Eighteen months later she presented herself in a very similar condition with ascites and a right-sided tumour. Respiration was very much impeded by the distension of the abdomen, but the laparotomy scar had not yielded. The abdomen was opened for the second time in

Digitized by Google

November, 1896, and a similar tumour was removed from the right side together with about six quarts of ascitic fluid. She rallied well after the operation, but died about six weeks later with all the clinical appearance of malignant disease; the post-mortem examination showed that it was an unusual form of recurrence.—Mr. O'SULLIVAN said that he examined both tumours after their removal and found both of them to be papillary cystic tumours, which appeared to him to be of a benign character. At the post-mortem examination he found an extensive fibrinous peritonitis. No secondary growths were found except in the peritoneum. He regarded it as a case of peritoneal infection by dissemination of the tumour cells through the abdominal cavity.

Dr. ALFRED SMITH showed three large Dermoid Cysts of the Ovary, which extended in each case above the level of the umbilicus. The patients made good recoveries.

Dr. KIDD exhibited a Double Dermoid Cyst removed from a patient aged thirty-three years. The larger tumour was of the size of a fœtal head, and the smaller one of about the size of a goose's egg. The patient made an uninterrupted recovery.

Memories of Seven Campaigns: a Record of Thirty-five Years' Service in the Indian Medical Department in India, China, Egypt, and the Soudan. By JAMES HOWARD THORNTON, C.B, M.B, B.A., Deputy-Surgeon-General, Indian Medical Service (Retired), late Principal Medical Officer, Punjaub Frontier Force. With an Introduction by A. EGMONT HAKE, Author of "The Story of Chinese Gordon," &c., and Editor of "General Gordon's Journals at Khartoum." Illustrated by EDWARD THORNTON, A.R.I.B.A., and KATHERINE MARGARET THORNTON. Westminster: Archibald Constable and Co. 1895.

THIS is an age in which military and naval celebrities have collected and published their experiences and memorials. There has been of late quite an epidemic of this form of literature, beginning with a renewal of interest in everything relating to the greatest military, but not the most benevolent, character of modern times—the first Napoleon. The great literary success of the present time—owing to the easy, fresh, and natural style in which it is written, and the pleasant narrative form and varied character of its author's experiences—is probably the work by Lord Roberts. We are glad to welcome a book by a medical officer of long and distinguished service giving a record of his thirty-five years' service in India, China, Egypt, and the Soudan in connexion with the various campaigns in which he took part, together with the observations and impressions he has derived while serving in those countries. This volume serves to show how interesting and diversified an Indian medical officer's work and experience may be. The author entered as a student at King's College in 1851 and matriculated at the University of London in the same year. After going through the usual course of lectures and hospital attendance for two years he passed his first M.B. examination, and a year later took his degree of B.A. with honours, and in 1855 he became M.R.C.S. of England. He was selected by the Council of King's College Hospital for an appointment of assistant-surgeon on the Bengal medical establishment of the East India Company's service, and pending his reaching the age of twenty-two, before which time he could not be admitted into the service, he passed his final examination for the degree of M.B. Lond. in November, 1855. In March, 1856, he embarked for Calcutta, and the voyage out *viâ* the Cape occupied some three and a half months. He arrived at the mouth of the Hooghly River on June 28th following. It is worth mentioning that he was much struck by the beauty of the river banks and the mansions of Garden Reach scattered at intervals, as well as by the imposing appearance of the city. A closer view, however, soon dispelled these impressions. The sanitary condition of Calcutta is, we know, not all it should be at the present time, but it is certainly better than it was then. After remaining at the General Hospital in that city for about two months he was ordered to the Benares circle for duty. Shortly afterwards the Indian Mutiny commenced, and he was soon plunged into the midst of all the exciting and trying circumstances of that eventful time. This was followed by the war with China and various military expeditions of one sort and another in India, Egypt, and elsewhere, including some of the smaller expeditions involving a good deal of that exposure and hardship which so often accompany our Indian mountain warfare. It would be impossible within the limits of space at our disposal to follow the author in his descriptions of all he saw and did in his diversified career, for these occupy some 359 pages, exclusive of the introduction. The book is well illustrated, and the author in his "memories" has a good deal to recount that is both interesting and instructive, especially to those more or less acquainted with Indian life and travel and desirous of renewing their acquaintance with that country and of tracing some of the changes that have taken place in it since the author first entered the Indian Medical Service. We are glad to notice, by the way, that he speaks highly of the advantages of this service, declaring that these are still, in his opinion, superior to the inducements held out by any other medical service in any part of the world. We wish, however, that he had said more about his medical, as apart from his military, experiences than he has done.

Speaking of the Indian Mutiny Deputy-Surgeon-General Thornton pays a tribute of praise to the admirable conduct of the majority of native domestics in the service of Europeans in India during that crisis. Throughout the volume there are interspersed various practical observations and comments of a medical, sanitary, and administrative character which, if they are of necessity in a work of this kind lightly touched upon and of a somewhat sketchy nature, are, nevertheless, pertinent and useful. For instance, speaking of the climate of Hong-Kong and of the prevalence of malaria in connexion with emanations from disintegrating granite, he adverts to the necessity of leaving newly-erected buildings unoccupied for some time in order to safeguard the inmates against fever—a very necessary precaution where the soil has been excavated to make new foundations. He remarks that he has always regarded the burning of the Summer Palace in the war with the Chinese as a regrettable act of vandalism which destroyed some beautiful buildings and works of art, while it was altogether futile and ineffectual as a punishment for Chinese treachery and cruelty. The chapters dealing with Deputy-Surgeon-General Thornton's experiences in Egypt and at Suakin are distinctly interesting. The absolute immunity of the soldiers of the Indian contingent from enteric fever, from which officers and men of the British force suffered so much, the surroundings and general conditions in both cases being precisely the same, has not, he thinks, ever been satisfactorily explained. In addition to the descriptions of the more purely military part of his experience there are a number of incidents scattered through the volume which serve to enliven its pages. There is, for example, a droll story of an officer having sent in a report to the superintending engineer of the district of some interesting Buddhistic remains he thought he had discovered on the Kashmir road. These remains proved eventually to be the ruins of some bridges which had been erected many years before by an engineer of the district, but had been in great part carried away by the force of hill torrents. The feelings of the superintending engineer when this became clear to him may be readily imagined. We have said enough, however, we hope, to induce our readers to procure and peruse the book for themselves.

On Gall-stones and Cholelithiasis. By EDWARD MANSFIELD BROCKBANK, M.D. Vict., M.R.C.P. Lond. London: J. J. and A. Churchill. 1896. Pp. 301.

DR. BROCKBANK has in the short compass of this very handy volume produced a model monograph. There was, as he says in the preface, a "want in our literature of a work containing an account of the present condition of our knowledge of the disease." This want can no longer be said to exist. The book consists partly of an admirable collation of the latest work on cholelithiasis in this country and abroad, and partly of original researches by the author into the solvent action of various drugs on gall-stones. After a good short description of the biliary passages, and the different forms of gall-stones and their seats of formation, Dr. Brockbank gives a very lucid account of the chemistry of cholesterin and its most probable origin. He accepts the view that it arises chiefly from the mucous membranes which line the biliary passages, and he brings forward many pieces of evidence to support his contention. "With the cystic duct completely obstructed or obliterated, so that the access of bile to the gall-bladder is impossible, the latter is often found to contain fluid without any trace of bile in it, and which to the naked eye is seen to sparkle with crystals of cholesterin, and calculi in such a sealed-up gall-bladder show evidence of growth from the deposition of pure cholesterin on them." "The cholesterin may be formed as a result of the degeneration of the cell elements of the mucous membrane, but it is also possible that some of the glands which exist in profusion in the wall of the biliary passages may secrete it." While this is the main method of formation, a little cholesterin "is secreted by the liver from the blood, in which it exists already as a product of the metabolism of the tissue of the body, especially of the nervous system." After pointing out that cholesterin is soluble in a solution of bile-salts, but naturally insoluble in the bile acid, Dr. Brockbank sums up against the theory that decomposition of the bile-salts in the biliary system is the cause of the precipitation of cholesterin. "In the present state of our knowledge on the subject the change from a bile-salt to its corresponding acid, or the decomposition of bile acids which is supposed to take place during life in the biliary passages, and which lead to precipitation of the cholesterin held in solution by the bile-salts, are points which must be considered to be not proven."

The author describes fully the action of soaps on cholesterin and the transformation of the solid cholesterin into a viscous body. In the third, fourth, and fifth chapters the methods of evolution of a gall-stone are discussed in detail. "In young people the cast-off epithelial cells (of gall-bladder and ducts) are pale, but in older people and those who have died of tuberculosis, acute febrile affections or heart disease, and always where calculi already exist in the gall-bladder, the cells contain many fat globules and myelin forms. The latter have almost the same appearances as the bodies which I have described as forming when a solution of soap acts on cholesterin. These myelin forms exude or escape from the cells and swim freely in the bile either singly or in clusters. ..... Naunyn considers that the above-mentioned soft, amorphous cholesterin masses are one form of rudimentary gall-stone; and he also describes another form of rudimentary stone which consists of cholesterin in a hard, vitreous, amorphous condition, but which sooner or later shows evidence of crystallisation. ..... I have myself frequently seen both the soft and hard form of amorphous cholesterin occurring with the clusters of myelin forms, but I think that rudimentary calculi can arise in yet another way. I have explained previously how the soap-cholesterin bodies under the action of water lose their compound nature and are broken up, the cholesterin being deposited in the crystalline form. I have very frequently watched the myelin forms in bile from day to day, and have seen how they gradually disappear, and how crystals of cholesterin develop with great rapidity and in great profusion, and the question occurred to my mind as to whether the crystals which form in bile might not be deposited from the myelin forms by a process analogous to that which leads to their formation from the soap-cholesterin bodies." The part played by micro-organisms in the production of gall-stones, and the conditions under which they may be present in the bile are amply detailed. "If the presence of micro-organisms is an exciting cause of the formation of biliary calculi, it probably acts by the bacilli setting up a stone-forming catarrh of the mucous membrane of the biliary passages." The effect of nitrogenous food in increasing the production of bile-salts favours the view that gall-stones tend to occur more readily in people who eat sparingly of nitrogenous compounds.

The clinical and pathological portion of this book is well written. All the ordinary forms and complications of cholelithiasis are graphically set down and the differential diagnosis is clearly given, and a brief record is added of the rare abnormalities that may occur.

Chapter XIII., on the Medical Treatment of Gall-stones, shows judgment and balance. Dr. Brockbank admits that "not one new remedy of any great value has been discovered since Coé's time (1750)," and then proceeds to show how the old remedies may help, and in some cases even cure, the patient. He relates some experiments to test the solvent action of alkalies on gall-stones. "I found that the alkaline salts which occur in the various mineral springs, even when in strong solution in water, have not the slightest solvent action on a gall-stone. I kept gall-stones in solutions of the salts of various strengths, maintained at the body temperature, for periods of time varying from two to four weeks without there being any loss in the weight of the calculi at the end of the time." Various means were used for producing movements of the stones in the fluids, to imitate as far as possible the movements of the gall-bladder, but with no better result. And yet for various reasons the good results of a course of Carlsbad waters are absolutely beyond question. The effect of large doses of oil are also discussed. Chapters XIV. and XV. are devoted to the surgical treatment of gall-stones.

The volume is well worth careful reading, and gives a good account of our present knowledge of the subject.

A Practical Treatise on Mechanical Dentistry. By JOSEPH RICHARDSON. Seventh edition, revised, enlarged, and edited by GEORGE WARREN. With 692 Illustrations. London: J. and A. Churchill. 1897. Pp. 670. Price 22*s*.

THIS book is so well known that anything like a systematic review is hardly called for. That a seventh edition has been reached is alone sufficient evidence of its worth as a text-book on mechanical dentistry. The necessary knowledge and skill for the manufacture of dentures, crowns, bridges, &c., can only be properly obtained by constant practice, and it goes without saying that the mere reading of a text-book is not sufficient to make a person proficient in dental mechanics, but when reading is carried out in conjunction with actual practical work, then a book of this character becomes extremely valuable. Mr. Warren, who has edited this edition, is to be congratulated upon his work, for he has included all the most recent improvements, this being more especially noticeable in the chapters dealing with appliances for the Correction of Dental Irregularities and Crown and Bridge Work, while he has also found room for an excellent little chapter on Electricity and its Application in Dental Mechanics. The chapters on the Restoration of Palate Defects and Fractures of the Maxilla and Mandible should prove useful to the general medical practitioner. The latter subject is very fully dealt with, only, curiously enough

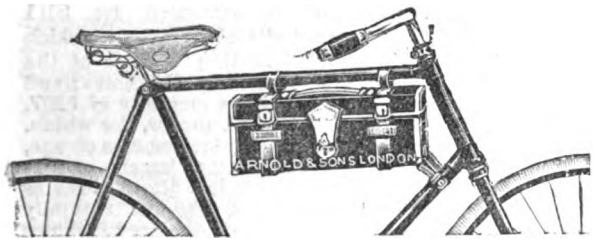
we find no mention of Hammond's splint, a method most valuable in the treatment of fractured jaws.

JOURNALS AND REVIEWS.

THE *Journal of Anatomy and Physiology*. Conducted by Sir WILLIAM TURNER, F.R.S., and J. G. M'KENDRICK, M.D. Aberd., F.R.S. Vol. XXXI. New Series, Vol. XI. Part 4. July, 1897. London: Charles Griffin and Co. Price 6*s*. —The death of Sir George Humphry, who was one of the founders of this journal, has led to the reorganisation of the editorial staff, and in future numbers the editors whose names appear upon the present title-page will be joined by Professor Alexander Macalister, of Cambridge, Professor D. J. Cunningham, of Dublin, and Professor G. D. Thane, of London. The present part contains the following articles: 1. On the Action of Infused Beverages on Peptic and Pancreatic Digestion, by James W. Fraser, M.D. Edin. Dr. Fraser finds that infused beverages, such as tea, coffee, and cocoa, as a rule retard peptic and possibly tryptic digestion of albuminoid food stuffs as compared with the rate of digestion with water as the beverage. There are, however, certain exceptions. Tea and coffee, for example, do not retard the digestion of eggs and salted meats. The active agent in the retardation is chiefly tannic acid in the case of tea and coffee, but in the case of cocoa it is due to the suspended solids. Numerous elaborate tables are given. 2. On the Existence of a Sterno-coracoidal Articulation in a Fœtal Marsupial, by R. Broom, M.D. Glasg. 3. Notes on the Duodenum and the Pylorus, by Thomas Dwight, chiefly dealing with the position, size, and form of these parts as deduced from casts. 4. On Some Points in Comparative Myological Nomenclature, by Professor Bertram, C. A. Windle, of Mason College, Birmingham, and F. G. Parsons, F.R.C.S. Eng., of St. Thomas's Hospital. 5. A Case of an Additional Presacral Vertebra, by Dr. R. J. Gladstone. 6. On the Structure of Cross-striated Muscle and a Suggestion as to the Nature of its Contraction, by W. M'Dougall. In this article the wing muscles of insects and the skeletal muscles of the cray fish are chiefly considered. 7. The Rolandic and Calcarine Fissures: a Study of the Growing Cortex of the Cerebrum, by D. J. Cunningham, F.R.S. 8. Case of Anomalous Kidney and Ureter, by T. W. P. Lawrence. 9. Notes on the Myology of a Negro, by Thomas H. Bryce, M.B. Edin., of Queen Margaret College, Glasgow. 10. Replies to Questions issued by the Anatomical Society of Great Britain and Ireland, by William J. Alexander, M.A. 11. Note on the Dissection of a Third Negro, by Sir William Turner. 12. An Experimental Research upon Cerebro-Cortical, Afferent, and Efferent Tracks, by David Ferrier, F.R.S., and W. A. Turner, M.D. Edin., of King's College. This number contains the completion of the index to Vols. XXI. to XXX.

The *Archives de Médecine Navale et Coloniale* for June contain several interesting contributions, but among them there is nothing *hors ligne*, as our neighbours would say. Dr. Bartet of the *Étoile* leads off with some observations on an infectious disease which he met with at Jeddah in 1895. By the light of subsequent experience he is inclined to think it was Indian relapsing fever, but at the time he believed himself confronted by a new disorder. The paper illustrates the difficulty that is sometimes felt by colonial and naval medical officers in arriving at a correct diagnosis for lack of access to reference libraries. A report on disinfection by means of chloroformol follows; and then, under the head of Practical Surgery, there is a useful paper by Dr. Lassabatie on the necessity for a uniform system of colouration for antiseptic solutions, so that the attendants who are liable to frequent changes of station may not be led into error. According to a tabular statement supplied by the author each naval hospital in France would seem to have its own special colour. Dr. Lassabatie recommends that solutions of corrosive sublimate, carbolic acid, and boracic acid, which are the three microbicide substances generally employed, should be tinted respectively blue, red, and yellow, sterilised water, which is becoming more and more popular every day, alone remaining colourless. Amongst the other papers there is one (illustrated) by Dr. Hercouet on the little known Gilbert Archipelago, which extends on either side of the equator about the centre of Micronesia. These islets are very poor and unproductive, but the writer regrets that his Government failed to establish a protectorate over them when the opportunity offered some time ago. As matters now stand the neighbouring British plantations in Queensland alone derive benefit from the labour of the population, which is estimated at 41,000 persons. The number also contains Notes on a case of Complete Dislocation of the Knee by Muscular Action; a Short Account of a Cure of Snake-bite by means of Dr. Calmette's Serum; a Description of the Effects of Sea-Water on Cast Iron after Prolonged Immersion, by Apothecary Le Naour; and the conclusion of Dr. Neiret's paper on Medical Matters in the Island of Mayotta.

Appleton's Popular Science Monthly. July, 1897.—This number is full of interesting papers. Dr. Shufeldt contributes an attractive paper on "Some Facts about Wasps and Bees." Under the title, "Let us Therewith be Content," Ellen Coit Elliott says some sensible things about "women's sphere." To the questions "Are scorpions matricides and suicides?" Dr. Juan Vilaro replies decidedly in the negative in the first instance and in the affirmative in the second. Professor Charles Ernest Pellew continues his interesting and amusing "History of Alcohol" He comments upon the disastrous results of gin-drinking occasioned by the encouragement given to its manufacture early in William and Mary's reign, when London streets abounded with gin-shops, and one could find placards on them reading "Drunk for a penny; Dead drunk for twopence; Clean straw for nothing"; &c. As is well known, this led to the passing of the famous gin law in 1736, but this did not completely eradicate the mischief, since apothecaries took to selling the stuff duly coloured in small vials, labeled "Colic Water," "Makeshift," and "Ladies' Delight." The writer concludes that the world has at last found out what intoxication means, and the disastrous effects of inebriety have taught a practical lesson which we venture to think has produced a far more salutary result than the fierce and violent, but well-meant, denunciations of teetotal enthusiasts.



The *Dublin Journal of Medical Science* for July leads off with an interesting paper by Mr. C. R. C. Tichborne on the Dissemination of Micro-Organisms and the Best Method of Destroying Germ Emanations from Sewer Gas. After referring to the two methods of germ transmission—namely, the "raft" method, where germs are borne on solid particles floating in the air, as in the desquamation of scarlet fever, and the method in which they are distributed by bubbles bursting on the surface of sewage—he lays down the proposition that sewage ought to be disinfected from the top by a mixture of antiseptics having a lower specific gravity than sewage, and the mixture he advises is made up of crude phenol 1 part, naphthalene ½ a part, and light coal-tar oil 3 parts. When mixed with sewage the tar oils will separate, forming a germicidal pellicle on the surface and trapping any germs sent up by bubbles, while the rest of the mixture will sink through the sewage, purifying it on its way. Dr. A. E. Boyd writes on the Report of the Vaccination Commission. He summarises the facts and conclusions arrived at, and he considers that the weakest part of their recommendations is that regarding revaccination, which he thinks might be made compulsory on school children.

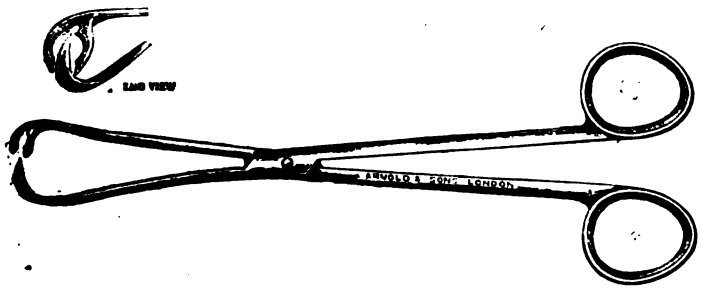
New Inventions.

NEW CYCLE MIDWIFERY BAG.

I HAVE suggested this bag to Messrs. Arnold and Sons, West Smithfield, as I have been unable to find a suitable one in which to carry instruments, &c., when cycling. Although I have planned it for a cyclist's midwifery bag, to be easily adjusted to the cycle even in the dark, it can, however, be



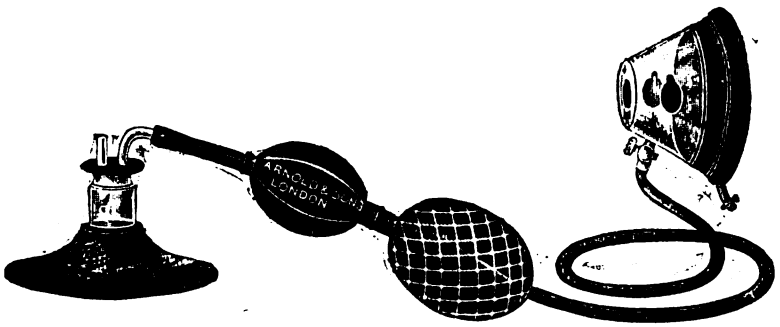
carried in the hand, as the straps are all removeable. It also forms a good useful all-round bag for the practitioner whether cyclist or not. It is of light weight and is made of stiffened water-proofed mail canvas bound with leather. It is carried on the frame of the cycle suspended from the horizontal tube by two detachable leather straps; these are passed through stout india-rubber rings before being attached to the bag in order to safeguard against concussion when passing over rough roads, and as they encircle the bag they give support to its bottom. Another detachable leather strap is attached at one end of the bag near the bottom and passed round the framework to prevent swinging. The bag is fitted with lock and key and a flat leather handle for carrying. Inside it is lined, and as the top is thickly padded and well overlaps the sides, the bag is when closed quite dust-tight. Near the bottom are six lappets of material fastened to the end of the bag. These are to be placed between the instruments. The bag, whilst holding all the usual obstetric instruments, has room for a pocket midwifery case, Higginson's syringe in case, hypodermic syringe in case, and Barnes's bags.

I am much pleased with the manner in which Messrs. Arnold and Sons have carried out my suggestions. The bag is neat, well made, strong, and serviceable, and I have found no harm come to either instruments or bottles, even over rough country roads. It is not in the way when riding, and even when filled its weight is hardly noticeable.

Bedford. JAMES C. CLARK, L.R.C.P. Edin., &c.

A NEW TONSIL FORCEPS.

THIS forceps is designed for use with the bistoury or sickle in removing the tonsils. It consists of a male barbless,



spear-shaped blade, concave below and with cutting edges, fitting into a female divided incurved blade the barbs of which are placed within the fenestrum. Its length is five and a quarter inches, and its end measurement is five-eighths of an inch. Two sizes are made. I claim for it (1) a gripping power greater than that of the forked or toothed volsellum, and that it does not tear through; (2) efficiency in grasping and keeping taut the pedicle of any enlarged growth in a roomy cavity; (3) there is no bar of arrest to its progress, and by keeping the blade of the bistoury close to the convexity of the closed end, there is no danger of wounding other structures or notching the knife, and the growth can be rapidly excised; (4) it can be used either side, and is of service when the guillotine (of which three sizes should always be kept) is objected to; and (5) with a Wingrave's gag and some eucaine both assistant and anæsthetics are unnecessary, and the operation of tonsillotomy is rendered painless and efficient by the use of this instrument and the bistoury. The instrument is made by Messrs. Arnold and Sons, West Smithfield, London.

Ealing, W. HERBERT A. SMITH, M.D. Durh.

A NEW APPARATUS FOR ADMINISTERING ANÆSTHETICS AND OTHER VOLATILE VAPOURS.

THE accompanying illustrations represent several forms of apparatus, designed by Professor Hobday, of the Royal Veterinary College, for the administration of anæsthetics and other volatile vapours, and shown before the members of the Society of Anæsthetists at their meeting in March last. Before being introduced into human practice they were thoroughly and successfully tested on a large number of veterinary patients (including over 400 dogs), in most cases for severe and varied operations, during a period of about two years.

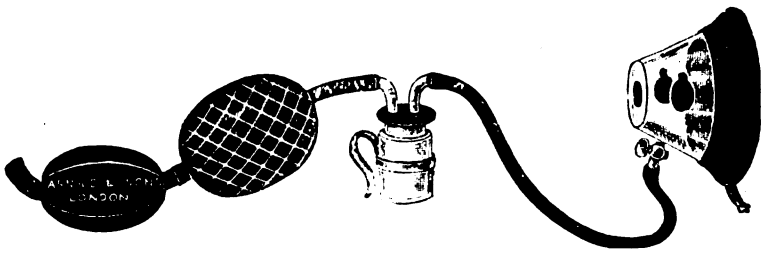
FIG. 1.

Shows the position of the bellows by which a current of air is *sucked* over the surface of the anæsthetic in the bottle, the mixed vapour being passed on into the mask.

The principle of the apparatus in Fig. 1 is to *suck* a current of air over the surface of the anæsthetic and to force a diluted vapour into the mask which is placed on the patient's face; this has been found to work successfully in the case of children, parturition cases, and for prolonged operations where a light degree of anæsthesia is required to be maintained, anæsthesia taking place in most cases quickly and without struggling.

In Fig. 2 a current of air is *forced* over the surface of the anæsthetic by means of the bellows, the size of the bottle and amount of surface exposed, together with the pressure exerted on the bellows, influencing the strength of the vapour; and in Fig. 3, which is designed with the idea of saving the trouble of pumping, the same idea (that of forcing a current of air over the anæsthetic) is maintained. In this latter case the pressure exerted by the compressed gas is regulated by a valve on the end of the cylinder, and the amount of vapour admitted can be adjusted as delicately as required by the aid of the tap on the lower part of the mask; one great advantage of this method is that the anæsthetist has both hands free to manipulate the mask. The cylinder method has been tested with both

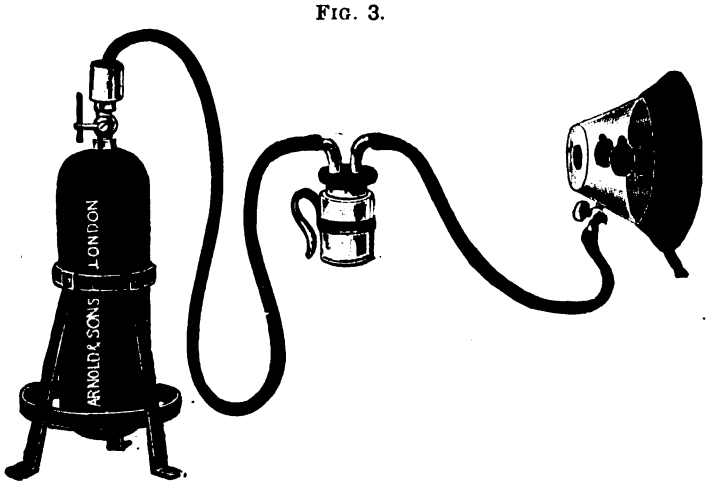
Digitized by Google



pressed air and oxygen, and the anæsthetics used in the bottle have been chloroform, ether, and mixtures of these anæsthetics with alcohol. It has also been used with a Junker's bottle when a more concentrated vapour was required.

It is needless to say that the strength of the vapour given with Figs. 2 and 3 is greater than that given by Fig. 1.

The chief advantages claimed are: 1. That the chances of overdose are minimised, the amount of anæsthetic used being exceedingly small (especially with the apparatus shown in Fig. 1) and only just sufficient to produce and maintain anæsthesia. This pattern is of especial value for midwifery cases where the practitioner often has to trust the administration of the anæsthetic to an unskilled person under his instructions. In a temperature of 60° F., with six drachms in the bottle, the vapour soaked into the mask contains one part of chloroform well mixed with 4200 parts of air. In the dog, on many occasions, unsuccessful attempts were made to destroy the animal by forcing the bellows as hard as possible for over half an hour, no dangerous symptoms even being manifested. 2. That the supply and strength of the vapour is much more regular and constant when taken from the surface than when proceeding from a current of air forced through an ever-diminishing quantity of fluid such as chloroform. 3. That the anæsthetic is less likely to become oxidised or otherwise changed by the air passing over the surface than if it was constantly passing through it. 4. That there is no fear whatever of irritant or rubefacient effects upon the face of the patient. 5. That by administering the anæsthetic so gradually there is no sensation of choking or other objectionable feeling on the part of the patient.



The apparatus can be obtained from Messrs. Arnold and Sons, West Smithfield, E.C. The cylinders can be supplied in any size, from one containing only a few cubic feet to those containing 100 cubic feet or more, the cost of the compressed air being merely nominal.

FIG. 2.

Shows the arrangement of the bellows whereby a current of air is *forced* over the surface of the anæsthetic in the bottle, the mixed vapour being driven into the mask.

FIG. 3.

Shows the arrangement whereby air, oxygen, or other compressed gas contained in the cylinder is made to pass over the surface of the anæsthetic in the bottle without any of the trouble of pumping; the pressure being adjusted by a valve on the cylinder, and the amount of mixed vapour admitted into the mask absolutely controlled by a tap on the latter.

ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH OF LIVERPOOL.

DR. HOPE'S Annual Report, recently issued, shows that the area of the city of Liverpool is now twenty and a half square miles, with an estimated population of 641,063. The chief causes of mortality are stated to be zymotic diseases, which accounted for 2311 deaths; constitutional diseases, to which were due 1809 deaths; diseases of the nervous system, causing 1492 deaths; and lung diseases, with a mortality of 3207. Diarrhœa caused 851 deaths, for which, among infants under three months of age, improper feeding was largely responsible, the deaths being fifteen times as numerous as among children naturally fed. The decrease of small-pox is shown by the fact that during the decade 1866–75 the deaths were 236 annually, against 10 annually during the decade 1886–95 The actual death-rate from all forms of tuberculous disease has similarly decreased from 4·3 to 2·9 per 1000 of the population. As regards rabies, the effect of the muzzling order has been the destruction since the year 1890 of 14,757 dogs, mostly worthless and diseased. The number of lodging-houses, of which at the end of the year 1896 there were 635 on the register, with accommodation for 13,585 lodgers, shows a decrease, due to the smaller houses being replaced by larger ones affording better accommodation. The sub-let houses on the register numbered 17,708 and the inspectors charged with their supervision made upwards of 83,000 visits. There were 5705 inspections of canal boats. The scavenging department removed 282,296 tons of refuse from 62,200 ashpits. The report concludes with the remark that "the diminishing rate of mortality effected in past years has been continued in almost every district of the city, and indicates a great diminution in the amount of sickness of a serious character and consequently suffering and loss." The report also deals with the city burial grounds. Interments still take place in eleven burial grounds within the city. As to the effect of these interments on sanitary conditions, Dr. Hope quotes a report of an inspector of the city engineer's department, in which he states that "a large quantity of black jelly was found adhering to the side of the sewer nearest the necropolis; the other side was of the natural colour of the rock. When this material was touched or pricked it emitted a frightful stench. The opinion of the other men and myself was that it came from the burial ground. One of the men at work was taken seriously ill and died while the work was in progress." The medical officer advocates the closing of all these burial grounds.

REFUSING TO DISINFECT AT BARRY.—On July 12th, at the Barry police-court, the agent of a house in which a case of small-pox had occurred was summoned by the Barry Urban District Council for refusing to disinfect the premises. The inspector stated that he served defendant with notice to disinfect on the 23rd ult, but he refused to comply. The magistrates fined the defendent 8*s*., the cost of the work done, and ordered him to pay the costs of the case.

THE CASE OF LEPROSY AT UPWEY, NEAR DORCHESTER.—Mr. Joseph Chamberlain, M.P., has interested himself in the case of leprosy at Upwey. The boy came with his parents from Singapore, where he is supposed to have contracted the disease. Mr. Chamberlain sent an expert to examine the boy, and on his report the Colonial Department has granted a pension of £15 to the unfortunate lad.

THE LANCET.

LONDON: SATURDAY, JULY 24, 1897.

THE Royal College of Physicians of London has enjoyed during its long career considerable Court favour. Instituted by HENRY VIII. "with a view to the improvement and more orderly exercise of the art of physic and the repression of irregular, unlearned, and incompetent practitioners of that faculty," the first President of the College appointed by the Royal Founder was his own body-physician and personal friend, THOMAS LINACRE. The association of the Court with the College, thus initiated, has been ratified many times in a striking manner by different sovereigns, as all can read by consulting the earlier biographical sketches in Dr. MUNK'S "Roll Call of the Royal College of Physicians"; and has now received its latest and most interesting confirmation by the gracious action of H.R.H. the PRINCE OF WALES in permitting himself to be enrolled as an Honorary Fellow. It had been an open secret in medical circles for some weeks that His Royal Highness might soon be expected to become a member of our profession by accepting a diploma from the College, and on Monday last the expected event became an accomplished fact when the PRINCE was admitted at Marlborough House to the Honorary Fellowship of the College in the presence of the President, Censors, Treasurer, and Registrar of the ancient and dignified corporation.

That members of the medical profession will regard this occurrence in more ways than one we have, however, reason to know, so that a few words explanatory of the significance of the event will not, we trust, be out of place. To some the granting of a purely honorary medical title will seem ridiculous, on whomsoever it is bestowed, if the recipient of the distinction has had no medical training and boasts no medical knowledge. These will hold, and with perfect loyalty in their freedom of thought, that, inasmuch as His Royal Highness cannot possibly know the elements of medicine, to make him a *socius compar* of the learned Fellows of the Royal College of Physicians of London is an idle and unsuitable compliment. The PRINCE OF WALES, they may say, is a practical soldier and expert sailor, so that there is a fitness about his Service titles which does not pertain in the case of his medical diploma. This view, although correct in a sense, gives a false picture of His Royal Highness's position. He is, it is true, a well-instructed military man, and although it is only the ritual of the military life with which he is familiar he is in possession of knowledge equipping him for high station in the Army, while hereditary bent and the necessary environment of the Courts of Europe have all combined to make this knowledge simple for him to comprehend and easy for him to apply. In a similar manner the PRINCE OF WALES is prepared for great offices in the Navy. We do not imply that he could command our fleet, but we more than imply that he could distinguish between good and bad naval policy and between efficient and inefficient nautical measures. But the facts—and this is the point—that the *bâton* of the Field Marshal and the uniform of the Admiral are not without their appropriateness to His Royal Highness's individuality, though true in the main, are quite by-the-bye. Nobody supposes that in actual war the PRINCE OF WALES could, if he were permitted to make the attempt, command our forces by land or sea. Everyone knows—and he as certainly as the rest of us—that he would be unable to meet the responsibilities, exactly as he would be unable to give a name to a nervous disease. He may know more of the elements of strategy than of physic, but his position in a campaign against disease is comparable for all practical purposes to the one he would occupy against an invading army.

The right way to regard the honorary titles of the PRINCE OF WALES is so clear that we are surprised to find that there should be any obscurity in the matter. He is the representative of HER MAJESTY THE QUEEN, who is the Fountain of Honour, and as such it is germane to his position that he should enjoy high official status in all our institutions—in our great departments and no less in our professional corporations. The Army and Navy fill places in our Constitution which no profession aspires to fill, but the professions have a claim upon the personal attention of the Crown which cannot be denied, and which the PRINCE OF WALES has always shown himself prompt to admit. The PRINCE OF WALES has done more than cement an historic friendship between the College and the Crown by his acceptance of an honorary diploma—much more. In his compliment to the College may be seen a pleasing recognition of the whole profession of medicine. We may interpret the event as meaning that the Heir-apparent, desiring to associate himself with all that is best, all that is most useful, and all that is most healthily progressive in the country, has designed to acknowledge the place of medicine in his comprehensive programme by consenting to become a Fellow of the Royal College of Physicians of London.

WE have striven to keep our readers *au courant* with the rise and progress of the epidemic of plague that has prevailed in certain parts of India, and we have also frequently alluded to the disasters by which that country has been afflicted in the shape of famine and quite recently earthquake. There has also been, in addition to the evils of pestilence and famine, a spirit of unrest among the natives which has manifested itself at Calcutta and at Poona. There is no evidence to prove that these two occurrences were directly connected with one another. The disturbances at Chitpur and Calcutta, of a kind not infrequent in India, arose from politico-religious causes, and the tragedies at Poona are supposed to have been connected with, and attributable to, the unpopularity of the measures adopted, and successfully adopted, for the repression of plague. The feeling against the authorities in this respect seems to have been greatly excited and fomented by the disaffected Mahratta press. All the evidence points to the murderous outrages at Poona having been the outcome of

Digitized by Google

a political conspiracy which had been long incubating, and in which a great many natives were involved, and quite probably the native police also. The opposition to the plague suppression measures and the false statements that had been spread abroad in regard to them simply afforded an occasion, however, for letting loose the passions of disaffected people. Still, looked at from any point of view, there is evidence of a spirit of unrest among portions of the native communities in India which cannot be entirely disregarded, although we do not in the least believe that there is any feeling of enmity to, or discontent with, our rule in India among the native population generally. It is easy to understand, of course, that there must be a conflict, whenever they come together, between Eastern ignorance, caste-traditions, and prejudices, and the methods adopted by modern Western civilisation—however carefully and considerately carried out—in regard to sanitation and the repression of epidemic disease. The natives of India are not, as we know, from examples in our own country, peculiar in their opposition and resistance to hygienic measures. But we are glad to learn that the recent crimes in Poona probably had not their roots altogether in this soil of enmity and prejudice, but in other sources of disaffection of a political kind.

The official and medical reports and modern literature regarding plague at Hong-Kong and India are becoming so voluminous that it is not easy to keep pace with them. We have before us an excellent report on the Prevalence of Bubonic Plague in the Colony of Hong-Kong during the years 1895 and 1896, by J. M. ATKINSON, M.B. Lond., D.P.H. Camb., Acting Colonial Surgeon; the report of the Commission sent by the Egyptian Government to Bombay to study plague, with a capital descriptive introduction from the standpoint of the practical sanitarian, by Dr. J. G. ROGERS PASHA, the Director-General of the Sanitary Department at Cairo, followed by observations of a scientific and technical kind on the nature and propagation of the plague, its cause, with the general symptoms and the clinical, pathological, and bacteriological features of the three forms of the disease encountered, by Dr. H. BITTER, the Director of the Institute of Hygiene, Cairo; and the Experiences and Lessons of the Bombay Plague, by THOMAS BLANEY, reprinted from the *Times of India*, dealing with the scourge from an epidemiological and public health point of view in relation to the three stages of its course as seen in Bombay—its initial or spreading stage, its second or stage of general spread, and its third or declining stage, as well as other papers and pamphlets. We have only time at present to glance at these sufficiently to extract and indicate their titles and nature. A Reuter's telegram from Berlin giving the results of the Commission under the direction of Professor KOCH has also just been published. Professor KOCH'S report states that the plague bacillus outside the human body or those of certain animals has very brief vitality. The duration of the life of the bacillus was found to be from eight to ten days at the most. The bacilli do not develop without the influence of atmospheric oxygen. Experiments on animals showed various results. Rats were found to be in the highest degree susceptible, and to be spreading the plague germs and communicating them to human beings. The Commission observed only isolated cases of illness among people camping in the open, while among those who had remained indoors the epidemic continued its ravages without abatement. Professor HAFFKINE'S system of inoculation, which was applied to 1400 patients, showed undoubted protective results, although a number of the patients were, it is stated, taken ill in consequence of the inoculation.

IT is a source of peculiar satisfaction to ourselves that greater attention is now paid to the sanitary condition of the river at Henley during the regatta week. There is, however, still room for improvement; but we believe—and there is visual evidence to that effect—that the worst sources of evil are, as far as possible, removed. It was during the regatta in 1886 that a LANCET Commission[1] conducted a practical inquiry on the spot, and the results of its investigations were by no means assuring. They led, however, to the framing of by-laws, which received the Royal assent in 1887, to the enforcement of which we attribute the improved appearance of the river now evident to everybody. These by-laws were framed to provide against the pollution of the river by sewage and other refuse occasioned by the sojourn of house-boats extending in an unbroken chain for almost a mile in length along the course. It must not be forgotten that the regatta at Henley attracts visitors from almost all parts of the world, and this may occur at a time when cholera is rampant in some parts; and the result of choleraic dejecta being thrown into the river might be the means of disseminating a disastrous epidemic amongst London water consumers. The intakes of the companies supplying London are not a very great distance below the Henley Reach, and at the annual regatta there are hundreds of persons housed on the river whose sanitary wants must of necessity be attended to. The Conservancy apparently kept a sharp look-out on the householders on the bank to prevent them from fouling the river in an open way, but it was obviously absurd and unfair to enforce this step when people living in house-boats for over a week on the spot were considered exempt from a similar enforcement. As we have said, the condition of the river, judging from last week's regatta, is still not entirely free from reproach, and we do not see why the regulations should not be made so rigorous as to stop all unnecessary disposal of refuse into the river. The nooks all along the course were full of pieces of bread, cucumber, tomato, disintegrated salads, and other débris which had at one time been succulent. If people throw these things into the river, wrongly regarding it as a proper receptacle for all kinds of rubbish, they will cast anything else into it without the slightest attempt at discrimination. And we fear it is possible that even human excreta are thus disposed of in contravention of those by-laws which our own inquiries aided in getting framed and enforced. One excellent plan which has been adopted is the attendance of a scavenging barge to collect the slops and dejecta early in the morning and to dispose of them on a comparatively remote piece of ground.

[1] THE LANCET Commission on Henley Regatta, THE LANCET, vol. i., 1886, p. 142; THE LANCET, vol. ii., 1886, p. 175; THE LANCET, vol. i., 1887, pp. 1254 and 1294; THE LANCET, vol. ii., 1887, pp. 28 and 84; THE LANCET, vol. ii., 1888, p. 84.

Digitized by Google

We should like to see this regulation supplemented by an an arrangement for collecting the innumerable floating bottles and items of waste food which accumulate in enormous quantities in the various havens along the course. These are a source of nuisance, not perhaps of the same intensity as human dejecta, but still easily removable. At any rate, the decomposing vegetable matters could be collected without much trouble, since, as a rule, they are located by the eddies of the stream. Such refuse certainly detracts from the beauty of the river. A similar complaint holds good with regard to racecourses and picnic grounds such as Epping Forest, where the visitors, utterly regardless of the comfort of others, cast corks, empty bottles, papers, and the fragments of an abandoned lunch in all directions. Such a disregard for clean and tidy manners may not be so serious a matter as the actual befoulment of a river with human excreta, but in one sense what is displeasing to the eye is objectionable equally with what is offensive to the nose. We do not know whether it is possible to trace the effects of the Henley week upon the purity of the water running down to the intakes below, but the rate of flow being known, and consequently the approximate time when such water is drawn by the companies, it would be interesting to observe the differences, if any, in regard to the quality of the water supplied to the metropolis during that period. It may reasonably be anticipated that a material increase would take place in the amounts of organic carbon and nitrogen, and *pari passu* the brown colour would exist in much greater relation to the blue, which is the normal colour of pure water.

THE Council of the Royal College of Surgeons of England at its last meeting repeated the expression of its inability to question the legality of the conduct of those of its Fellows or Members who accept the posts of medical officers of Medical Aid Associations and to endorse the refusal of any Fellow or Member to meet in consultation (particularly in urgent cases) registered practitioners if acting in conformity with their legal rights. This *non possumus* position of the College must be taken into serious consideration by the profession. The College is the disciplinary authority of the greatest number of the practitioners of the country. It has charge, not only of the major morals of its members, but, in a sense, of those minor professional morals which Sir JOHN SIMON said the General Medical Council could not undertake to regulate. It has powers of remonstrance and censure which in a large number of cases it is quite sufficient to use without proceeding to extremities. But, even so, it does not see its way to question the legality of conduct which on a large scale is lowering the public estimate of medical science and medical service. When medical men undertake the care of patients in such numbers as are inconsistent with due attention to individual cases, and when crowds of patients are gathered into monster associations by a system of touting which sweeps in thousands who are quite able to pay the ordinary charges of medical men, and which is grossly unfair to private medical men, we might have thought that a case had arisen for the exercise of the minor degrees of discipline of the Royal College of Surgeons and of its sister corporations. But the Council of the College has decided otherwise, and declares *non possumus*.

We need not suppose that the Council was unanimous in this finding. It may well be that opinion was divided on the subject, and that a little more importunity or the presentation of particular facts in some given case may suffice to move the majority of the Council to more activity and to more courage in the assertion of its disciplinary powers, given for the very purpose of upholding the methods of the profession and the essential conditions of honourable and successful practice. Another very important fact for the profession to notice, and especially those members of it who live in places where the working of medical aid associations and other such-like combinations do so much harm, is that the Royal College of Surgeons is only acting in this matter like all the other medical authorities. They all with one consent make excuse of one sort or another for doing nothing. The Royal College of Physicians of Ireland has expressed a pious opinion that its Members and Licentiates ought not to accept office in such associations. But it has gone no further. The reasons for such inaction and timidity are subjects for speculation. Perhaps the bodies which express them are acting on legal advice, though it is certain that if lawyers saw their profession degraded by such methods and systems they would undoubtedly find means within the domestic courts of their profession to check and control them. There have been some very gross cases of "touting" by associations which clearly violated all the rules that medical men in their personal capacity observe towards each other as well as the spirit and letter of the by-laws of the Colleges touching unprofessional methods of practice. One chief part of the explanation is an indisposition, as it were, on the part of the corporations to undergo the trouble and the expense of using their disciplinary powers, and a desire to throw such trouble and expense on the General Medical Council, which has no mandate to deal with professional misconduct short of that which is "infamous," and which has only one punishment—that of removal from the Register. Clearly the framers of the Medical Act in so restricting the disciplinary powers of the General Medical Council never contemplated relieving the qualifying bodies of their proper duties towards their members.

All this is very obvious. The situation is serious. The profession is left without any help from its authorities, and medical officers of medical aid associations may well retort on their accusers and say: "You see we are doing nothing that the bodies which gave us our diplomas disapprove or find illegal." It may be said that there is no more to be done. Let things drift, and let each man do what seems right in his own eyes. We do not take that view. We would urge the profession to organise itself in every important town and centre, and to assert itself. Combination in the trade-union form of "striking" is not, perhaps, to be commended. But there is such a thing as the public opinion of the profession, and we have great faith in that if temperately expressed and asserted. We are quite at one with the Royal College of Surgeons in thinking that, in urgent cases at least, consultation should not be denied. But, short of the extreme course of denying consultation, much may be done

Digitized by Google

to make the medical officers of these associations feel that they are acting selfishly and contrary to the interests alike of the public and the profession. The profession must save itself and show itself superior to the corporations, which act too much as if they had no interest in the profession further than to submit students to examination and to receive their fees. The profession will err deeply if it depends on either the General Medical Council or the medical corporations. It must in every district assert itself in strictly professional ways. One way that has, perhaps, not been tried quite so much as it should have been is that of treating directly with the leaders of the associations which are acting with such a high hand and with so little apparent generosity towards the profession. We do not share in all the sentiments that are expressed about working under a working-man's committee. Working men are not naturally ungenerous or ill-disposed towards the profession. They are amenable to reason and to argument. And we should advise in such centres as Portsmouth, Norwich, and Beckenham further attempts to treat directly with the associations themselves.

Annotations.

"Ne quid nimis."

UNHEALTHY PAUPER CHILDREN.

WE have already referred at some length to the important subject of the disposal of pauper children suffering from ophthalmia, ringworm, and other contagious diseases, and such as are suffering from some mental or bodily defect.[1] An order was issued on April 2nd, 1897, by the Local Government Board placing the several classes of pauper children referred to under the care of the Metropolitan Asylums Board. The last-named authority has set to work with laudable promptitude, and has just received a report from a special committee appointed for that purpose. Considerable difficulty has been experienced in arriving at approximate numbers of the several classes for which the Board will have to provide, but the urgent necessity for some change of the kind now taking place is apparent from the figures given, which for obvious reasons are probably under- rather than over-estimated. At the present time it is reckoned that provision will have to be made for about 800 cases of ophthalmia, 400 cases of ringworm and contagious diseases of the skin, approximately 360 children showing some mental or physical defect, about 150 children remanded under a magistrate's order (Industrial Schools Act, 1866), and an unknown number of children requiring "convalescent" treatment—a total, excluding the latter, which amounts to 1710 children. It is proposed to take over and utilise existing institutions as far as possible, with the important provision that the existing cubic space shall be revised. We notice with pleasure that it is proposed to deal with mentally and physically deficient children quite apart from the others, and under the care of foster-mothers, in batches of about eight each. A special point is also wisely made in the report that in all cases such education as these several classes are capable of receiving shall be given to them; moreover they shall also be under medical treatment. We notice with some regret, on the other hand, that no recommendation is made as to the appointment of any medical inspector. Without competent medical inspectors, of whom one might perhaps be a woman, this scheme, which otherwise promises so well, will fail as surely as did the old system.

EGYPTIAN ANATOMICAL NOMENCLATURE.

M. VICTOR LORET, of Lyons, has recently succeeded in determining the true signification of two anatomical terms used in the most celebrated of ancient Egyptian medical papyri—that which is known by the name of its owner, Dr. Ebers. M. Loret has been enabled to succeed because of the large number of new texts of Egyptian writings, both upon monuments and manuscripts, that are now annually published. These two terms, which are among the very few in the papyrus which were still imperfectly understood, are those for groin and perineum. The former word had been recognised by Professor Stern in his "Glossary of the Ebers Papyrus," but he assigned no reason for its meaning, and the matter had been deemed unproven. M. Loret quotes some twelve texts corroborative of the conclusion and the matter is now beyond doubt. The other hieroglyphs denoting perineum have been deciphered by means of the contents of a magical papyrus in the Vatican, recently edited by Dr. Erman. This manuscript gives a series of incantation formulæ appertaining to every member and portion of the body, commencing with the head and terminating with the feet, the order being strictly preserved. The title for the perineum is placed in the list in the following succession: "dorsal vertebræ, anus, perineum, viril member, thighs." In conclusion, a hope may be expressed that among the thousands of Greek papyri discovered last winter in Egypt some translations of old Egyptian medical records may be found and thus render superfluous the time and learning hitherto expended in laboriously wresting the secrets of the ancient hieroglyphic writing.

THE CONSTITUTION OF DEAD AND LIVING PROTEID.

IT is simple enough by the ordinary process of permutation to suggest different constitutional structures of complex substances, but it is more satisfactory if the formulæ so derived are found to stand the test of investigation. There is not a more complicated substance than albumin or the proteid constituents which play so important a part in the human economy. Their percentage composition is easy enough to establish, but their exact constitution is another matter. It is comparable to the difference existing between the substance or bricks of a building and the architecture or structural form it exhibits when the bricks are placed in position. Chemically analogous examples afford a strong line of deduction in throwing light upon the constitution of complex substances, and Dr. P. W. Latham, of Cambridge, in a Croonian Lecture in 1886, based his arguments on the constitution of dead and living proteid on some simpler types of chemical change. He assumed that the action of the liver on the amido bodies, glycocoll, taurine, leucine, tyrosine, &c., is one of dehydration similar to that by which glycogen is produced by the dehydration of glucose. Again, in accordance with Pfluger's view, ammonium cyanate is the type of living and urea of dead nitrogen, the conversion of the former into the latter being an image of the essential change which takes place when a living proteid dies. Further, in many of the cyanogen compounds condensation of three molecules take splace, forming compounds much more stable than those consisting of one molecule only, such as is exemplified in cyanuric acid, which results from the condensation of three molecules of cyanic acid. Dead albumin may be built up on the evidence furnished on the lines here suggested. The change from the dead to living albumin may be similarly supposed to take lace as from urea into ammonium cyanate. Dr. Latham

Digitized by Google

proceeds to adduce evidence explanatory of the changes which take place as the living proteid dies. His latest conclusions are as follows: (1) that living proteid consists of a series of cyan-alcohols with one thio-alcohol united to a benzine nucleus; (2) that when a proteid dies it gives off carbonic and lactic acid, the thio-alcohol by oxidation being converted into a sulphonate which combines with ammonia, and by the conversion of CNOH into NH = CO the cyan-alcohols are changed into a series of amido bodies; (3) that by condensation of the lower cyan-alcohol and the separation of CNOH the higher cyan-alcohols are formed; and (4) that urea is formed by the separation of carbamic anhydride (CO = NH), which either combines with ammonia to form urea or is hydrated to form carbonic acid and ammonia.

SPORADIC INFLUENZA.

DR. OTTO LINDENTHAL, of the Vienna Pathological Institute, who has had an opportunity of examining eight cases of fatal influenza-pneumonia, contributed an interesting paper recently to the *Wiener Klinische Wochenschrift*.[1] He believes that during periods when there is no influenza epidemic the microbe which is the cause of it passes from one individual to another, producing sporadic cases which are indistinguishable, clinically and bacteriologically, from the regular affection as met with in epidemics. The microbe does not multiply in the air or ground or even in water, but seems to require the body tissues and secretions as a medium. He finds that the pleuritic effusion in influenza is not always purulent, but may be croupous, sereus, or even sanguineous; also that the nasal inflammation can be, and perhaps always is, due to the influenza bacillus alone, but that very frequently the pneumonia coccus and other pyogenic microbes are associated with it. The influenza bacillus varies a great deal in size and shape from the smallest coccus-like rod to bacilli as large as those of diphtheria. All forms, however, retain their characteristic properties—difficulty of staining, immobility, refusal to take the Gram stain, special development in hæmoglobin, and deficient development at summer temperature or when deprived of oxygen. The colonies are at first developed in an arched or semi-spherical form and are homogeneous and transparent, and when allowed to grow freely have a friable appearance in the centre, afterwards becoming less arched and bluish when seen by transmitted light, or even so dark that they lose their translucency. As to the so-called pseudo-influenza bacillus which has been described, Dr. Lindenthal does not appear to believe in its existence.

MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE additions to the Museum of the College during the past twelve months include many specimens of great interest and importance. Among the pathological specimens may be mentioned the scalp of a Chinaman which had been torn off owing to the pigtail having become entangled in some machinery (presented by Mr. Stanley Boyd); three very interesting specimens of diffuse sarcoma (lymphadenomatosis) of the sternum, ribs, and spinal column (the bones are extensively invaded by the new growth); a specimen of the sac of an obturator hernia, and one showing the partial enterocele which had been contained in it. Mr. D'Arcy Power has presented six specimens which illustrate the pathology of experimental intussusception. A very good specimen of dissecting aneurysm of the aorta was presented by St. Bartholomew's Hospital, and Mr. J. Tweedy and Mr. C. D. Marshall have given fifteen specimens exhibiting various macroscopic lesions of the eye. A very good example of a conical stump is shown; the bone projects about three inches beyond the muscles, but is covered with skin; it was removed from a boy, fifteen years old, who had had his arm amputated nine years previously. Among the teratological additions two specimens are especially worthy of note; one was a case of complete ectopia cordis, the heart lying uncovered on the surface of the thorax, yet the child lived some hours; the other specimen was presented by Mr. Bilton Pollard; it is a diverticulum of the ileum, which was contained in the sac of a congenital umbilical hernia; it measures nearly three feet in length, and was attached about five feet and a half above the ileo-cæcal valve. In the physiological series fourteen specimens illustrating elastic structures have been added, the tunica abdominalis of the horse and elastic spinal ligaments of several animals being especially well shown. Then follows a large group of specimens illustrating the varieties of joints; these are divided into (1) joints without known function, mostly the result of periodicity in rate or nature of growth; these are illustrated by specimens of the jointed branches of some euphorbiæ; (2) joints which are points of development of organs, separated by internodes that effect the necessary elongation, well shown in an equisetum; (3) joints that allow of continuous growth (the best examples of this form are the "shell" of an echinus, the separate plates of which it is composed having been taken apart), and the carapace and plastron of a tortoise; (4) joints that by allowing motion diminish the risk of fracture; in a multi-nucleate calcareous alga (cymopolia barbata) the branches have flexible nodes alternating with brittle calcareous internodes, and in a bryozoan (membranipora membranacea) encrusting a seaweed the calcareous lateral walls of each zoœcium are interrupted in certain places by flexible areas that allow the bryozoan to adapt itself to the movements of the seaweed; and (5) joints that allow of voluntary motion, as in the chelæ of a lobster (homarus vulgaris) and in the joints of vertebrates. Many other specimens might be mentioned, but we have space for a few only: several most exquisite dissections of the nervous systems of a scorpion, a cuttlefish, and other invertebrates, and a skeleton of a snake (dasypeltis scabra) which feeds on eggs that it swallows whole, the shell being afterwards broken in the throat by the sawing action of thirty-two tooth-like processes borne on the anterior vertebræ. Professor Stewart and Mr. Targett are to be congratulated on the excellent specimens which have been added to the Museum, and great praise is due to the anatomical assistant, Mr. R. H. Burne, for the numerous careful dissections which he has made.

THE HOXNE DISTRICT COUNCIL AND THE NOTIFICATION ACT.

THE Hoxne District Council have some curious notions as to the duties of medical officers of health. The chairman of the council has evidently been under the impression that it was a necessary part of the duty of a medical officer of health to visit and see each patient concerning whom he had received a notification certificate; but, having been to head-quarters in London to ascertain whether he was right, he announced at a recent meeting of the council that there was no such compulsory duty on the part of the medical officer of health. We have explained again and again that the responsibility of visiting or not visiting premises on which there is infectious disease rests with the health officer and with no one else. He is the judge as to whether such a visit is necessary. It would, indeed, be absolutely impossible for medical officers of health in London and other large towns or in combined districts to make such visits in all cases, even if their authorities supplied them with

[1] Wiener Klinische Wochenschrift, No. 17, quoted in the Allgemeine Medicinische Central-Zeitung, No. 57, 1897.

Digitized by Google

unlimited means for travelling in the swiftest manner possible. Besides which, ten cases of scarlet fever—or of measles where notifiable—may not in one case call for a personal visit, whereas one single case of scarlet fever at a dairy, or of typhus fever in an ordinary town, would probably call for an immediate visit. The question is one for medical judgment, and this has been explained clearly by the Local Government Board. But the chairman and others referred also to visiting the "patient." As a general rule, this is absolutely unnecessary and altogether uncalled for. The medical officer of health is bound to act on the diagnosis formed by the certifier unless he has ground for suspecting fraud or unless some imminent danger to the district is involved. Visits by medical officers of health to patients of other practitioners have been officially denounced as unjustifiable except under the circumstances named; and even where they have to be paid, any such visit should only be made after communication with, and in conjunction with, the medical practitioner in attendance on the case. In 1895 we dealt in a series of articles (which have since been issued in pamphlet form) with all the various "Difficulties under the Infectious Disease (Notification) Act" which had been met with by medical officers of health and sanitary authorities, and we quoted at length a large number of decisions that had from time to time been given by the Local Government Board on the various questions that had been submitted to them in this matter. We cannot help thinking that if this *résumé* of difficulties and official decisions on them were better known there would be fewer instances of "allegations" against medical officers of health either as to excess of duty or failure of duty on their part. It behoves district councils like that of Hoxne to learn their powers and the duties of their officers before casting blame; and there are few points in which decisions have been more clearly enunciated than those which have, in this instance, led the Hoxne District Council into a wrong and altogether untenable position.

HIGH TENSION AND HIGH ALTITUDES.

A HOLIDAY contributor writes from Andermatt, Switzerland, on the 17th inst.:—"Alpine misadventure is a wide word and is made to include victims to pathological conditions unrecognised by the victims themselves, whose sudden fall into a crevasse or mountain torrent is set down to 'loss of balance,' 'misplaced footing,' or one or other of the many mishaps besetting the mountaineer, when syncope due to cardiac lesion was the real cause. In August, 1894, THE LANCET pointed out this 'error in classification' when Baron Paccoy, who had for two days been acting as guide to the Queen of Italy, stumbled and fell into a crevasse on the Lyskamm, not, as was at first thought, by inadvertence in walking, but by instantaneous heart failure occurring at the dangerous spot in question. May not this account for the strange disappearance of Mr. Cooper at Zermatt, now being investigated at the instance of our Foreign Office by the cantonal authorities? May he not have fallen into the Visp when suddenly overtaken by the syncope not unusual in a septuagenarian beside a rushing, brawling mountain stream? The hypothesis is well worth entertaining, strengthened as it is by the circumstances under which, on Sunday, the 11th inst., the burgomeister of a Westphalian town met his death on the Furka Pass. This gentleman, with his wife and a young Italian officer as *compagnon de voyage*, left Andermatt on the morning of that day for the Rhone Glacier. Everything went well till they came within sight of the object of their journey, when the burgomeister, rising in the carriage to get a better view, had barely uttered, 'Oh! C'est magnifique!' when he dropped down dead. The great altitude, the rarefied air, the high tension — conditions inseparable from Alpine ascents—were too much for a 'chronic sufferer from weak heart,' and he collapsed accordingly. Now, had this syncope occurred at a difficult spot of the Rhone glacier itself, had it supervened on the edge of a crevasse into which the victim fell, would not the incident have been classified as 'accident due to misadventure'—to one or other of the merely pedestrian risks encountered by every Alpine climber? The whole question opens up a series of considerations very gravely present to the Swiss medical faculty, in view of the multiplication of such engineering enterprises as the Jungfrau Railway, for example, which will shortly be 'ballooning' passengers of all ages and bodily conditions to a height of over 12,000 feet above the sea level. At a congress of the said faculty, held some time ago at Arona, the perils and the precautions incidental to such railway development were fully discussed, and an impressive warning was given to the travelling public not to venture on rapid ascents above the snow-line without previous sanction on the physician's part. To no section of that public is the warning more immediately addressed than to the British, who, after the exhaustion of the London season or a nine months' spell of work, professional or other, are found thronging every Swiss mountain inn, and in sheer holiday exultation qualifying by every kind of imprudence for some such fate as comes under the all too elastic heading of 'Alpine misadventure.'"

UNNECESSARY STREET NOISES IN AMERICA.

EFFORTS are being made in New York and in some other large cities in the United States to prevent as far as possible the unnecessary street noises. All over the world street noises in the large towns are a nuisance as well as a serious menace to health. Some of the noise must be endured as a necessary evil, but a great part of it might be easily abolished by judicious legislation, and to the lasting benefit of the general public. The worst feature of the case is that it is not only in the day time that the pandemonium is rampant; but at night too, when the nervous system absolutely requires rest, it is often almost impossible in a large city to obtain undisturbed repose. The matter is a serious one and will sooner or later have to be gravely considered. The noises prevailing by day and by night in New York are almost beyond belief. Englishmen are rightly prone to think that London is a noisy place, but compared with New York the American, we believe, looks upon London as a village. The noises in New York have a peculiarly jarring, irritating effect on the nerves; the booming rumble of the cable cars, the metallic rattle of the trains on the elevated railway, the jolting of the carts and heavy traffic over the rough, uneven roadways, the continual sounding of the gongs on the cars, the ringing of the bells attached to hucksters' carts,—all these combine to make up an aggregation of sounds which, happily, can be equalled in no part of London. In all large towns unnecessary street noises of any description should be sternly repressed. It seems absurd in these days of high pressure that to the unavoidable sounds should be added those which might be stamped out without doing harm to anyone.

MILK LEFT ON THE DOORSTEP: A SERIOUS POSSIBILITY.

ONE of the most curious early-morning sights in residential London is the innumerable cans of milk left on the doorsteps, or hung upon the railings, or upon the door-knobs, awaiting the advent of the domestic to take them inside in readiness for breakfast. Of course, it is done because the milkman calls at an inconveniently early hour, but the system has its decided disadvantages, not to say grave dangers. A case was reported at the Marlborough-street Police-court this week in which a man was charged with stealing two quarts of milk from outside a house in

Digitized by Google

Shaftesbury-avenue. The temptation to a famished man in the early hours of the morning, when he finds excellent food placed at the street-doors on every side, is indeed great, and so the magistrate thought, and taking that into account he sentenced the man to fourteen days' hard labour. This case prompts us to quote an instance known to ourselves in which the milk left in a can on a doorstep had been actually tampered with. Some maliciously disposed person had opened the lid and dropped inside a vermin-killing powder containing strychnine. Fortunately it was noticed that there was something wrong with the milk by the appearance of a blue powder in it, otherwise the consequences might have been very grave indeed, and with little chance of tracing the villain. We hardly like to suggest that there are miscreants amongst us who would be guilty of committing such a heinous offence, but the ease with which it obviously can be done, and was done in this case, should be a serious warning to the public to effectually prevent any such possibility. Milk consumers should insist on their milk cans being sealed, and should reject the early morning milk if it be found that the seal is broken.

MULTIPLE MELANOTIC SARCOMATA RESULTING FROM A MOLE.

The following case has recently been published by Dr. D. Grant.[1] The patient was a muscular, exceptionally healthy man, aged twenty-seven years. He had a black mole on the right arm ever since birth. Three years ago it was torn by the horn of a sheep and soon healed. Some time afterwards he injured it again, and it spread to the size of a finger-tip. A year after the first injury he showed it to a medical man, who thought little of it. Six months later he bruised it again. Healing did not take place readily, and a few satellites appeared. Another medical man excised the whole affected area of skin. Five months later a lump appeared in the axilla which was promptly excised. However, a large number of secondary growths appeared. The surface of the body was thickly sprinkled with melanotic growths, varying in size, depth, and colour, and a much larger number could be detected by touch. The whole skin of the trunk was thickly infiltrated with minute growths. This case, unfortunately, is a type of all. That melanosis may result from a mole is but a commonplace doctrine; yet in no case has free excision be resorted to in the first instance. The reason is that the first changes—increase in size or ulceration—appear trifling. The nature of the disease is recognised too late—when secondary growths have appeared. How many more such cases must occur before it becomes generally realised that a mole is a potential sarcoma and should be promptly and freely excised on showing the slightest activity?

RAILWAY NOISE AND VIBRATION AND THEIR EFFECT UPON HEALTH.

VIBRATION and noise are factors well known not only as producing temporary discomfort but also injurious effects upon the health. In these days when travelling rapidly from place to place is a *sine quâ non* both causes of disturbance are to some extent inevitable, but we cannot help thinking that much more might be done to alleviate the distress arising from our incessant recourse to the many and various means of moving from place to place. Speed is the craze, but there is no reason why speed should not be attained without the discomfort due to noise and rapid vibration, not to mention the, perhaps, permanently ill-effects which a constant series of joltings may have upon the nervous passenger and invalid. The various railways running out of London afford a good illustration of what is, and what is not, done in this direction. Passengers, for example, cannot fail to have noticed how smooth and free from vibration is the travelling on the Great Western Railway. On the London and North-Western and the Midland Railways it is still good from this point of view, but not quite so free from shock and noise. The trains of the former company running on the Underground Railway are, however, excellent examples of smooth and comfortable travelling. The trains running south create, as a rule, an endless clatter, so that on these lines a journey, say of fifty miles, produces as much distress and fatigue as a journey of over 300 miles north by the east and west coast and the Midland routes. It is fair to add, however, that the London and South Western Railway has of late years considerably reduced the amount of shaking which passengers on this line were wont to experience. The Great Eastern Railway, though well to the fore in enterprise, is, perhaps, one of the worst from the point of view of a rattling, shaking, and noisy journey. These differences are, of course, easily explained on engineering grounds. The character of the "run" is dependent upon the degree of perfection of the rolling stock and the track. What we should like to know is why the same standard of smoothness and regularity in both these engineering details cannot be adopted by all companies alike. The question is not one that affects the interests of the passengers only, because surely the more smoothly a train runs over the metals the less must be the wear and tear to both the train and the track. It will be generally conceded that every effort should be made to minimise the ill-effects which travelling at a high speed is apt to induce.

[1] Intercolonial Medical Journal of Australia, May 20th, 1897.

HOT WEATHER IN NEW YORK CITY.

THE weather in New York is said to have been the hottest on record for the first week in July. Heat makes itself felt in a peculiar degree in New York owing to the humidity of the atmosphere. When the thermometer approaches the hundred mark the heat is almost unbearable in the sun. Already there have been many casualties from the effect of the heat. On July 5th, when Independence Day was celebrated, what with the thermometer at 94° F., and the noise and smell of the numberless crackers and other descriptions of fireworks which supplied a vent for the overflowing patriotism of young America, life (a correspondent writes) was scarcely worth living. Without doubt, if this weather continues, as it is predicted it will, the scenes of last July will be repeated, when horses and men died in large numbers in the streets.

THE PHYSIOLOGY OF THE ADRENALS.

A LONG and interesting article on the Physiology of the Suprarenal Bodies is to be found in the June number of *Pflüger's Archiv*, written by Dr. Arthur Biedl, one of the assistants in the Vienna Institute. The points to which he has directed his particular attention are the vaso-motor nerves and the secretory nerves of these organs. He describes in detail the operative procedure he adopted in his experiments, and arrives at the conclusion that certain vaso-dilator fibres run in the splanchnic nerves to the adrenals, partly because no other explanation can be offered of the rapidity with which hyperæmia follows stimulation of these nerves, partly on account of the steady increase of the hyperæmia as the stimulation is continued, and partly because of its continuance for some time after the cessation of stimulation quite independently of the blood pressure in the arteries. He has observed that in the dog the splanchnics, after traversing the diaphragm, give off on each side, before they enter into the formation of the solar plexus, a single large branch to the adrenals, and these, he believes, contain the chief vaso-dilator fibres, since, if divided, the stimulation of the splanchnics in the

Digitized by Google

thorax is without influence, whilst stimulation of the distal extremities of the divided nerves is followed by active hyperæmia. From a critical review of the researches of previous investigators he considers the facts actually established in regard to the vaso-dilator nerves distributed to the abdominal viscera to be that these nerves leave the spinal cord chiefly by the anterior roots of the lower dorsal nerves and, running in the rami communicantes, enter the sympathetic in the dorsal region and are distributed with the branches of the splanchnic nerves to the large and small intestine, the liver, kidneys, pancreas, and adrenals. He has satisfied himself that there are ganglia on the vessels distributed to the adrenals, and that although their presence has not been anatomically demonstrated vaso-constrictor nerves exist. The two sets of nerves, vaso-dilators and vaso-constrictors, run in the same trunks, their relative proportion varying to a considerable extent. Dr. Biedl has devoted much time and attention to the secretory nerves of the adrenals. These organs belong to the class of those which have an internal secretion discharging the materials they elaborate into the blood. Various investigators have been led to the belief that the granules well known to exist in the blood of mammals proceed from the adrenals. Others have shown that the venous blood of these organs resembles arterial blood in colour, and yet another observer has demonstrated that the peculiar extract of the adrenals is not a post-mortem product, but is contained in the venous blood returning from these organs during life. Dr. Biedl, in his experiments directed especially to the determination of the changes in the morphological elements of the venous blood and the behaviour of the extract with its peculiar action on the blood pressure, found that after stimulation of the suprarenal branch or of the splanchnic nerve in the thorax the number of bright granules or little masses of protoplasm was diminished, and at the same time the number of the leucocytes of the blood was reduced, these bodies being apparently retained within the organ. In regard to the active extract, Dr. Biedl believes that the splanchnic nerves do not only contain vaso-dilators, but that they are also associated with the secretory nerves of the adrenals, which run in the same trunks, and that stimulation of these nerves leads to some, though not material, increase in the quantity of the active extract produced.

DILATATION OF THE STOMACH IN INFANCY.

IT is well known that dilatation of the hollow viscera is a morbid condition commonly gradual in its development and equally, if not more, slow in its amendment. It derives, moreover, a peculiar interest from the fact that it constitutes a form of change which marks the transition between functional and organic disease—a stage at which overwork and weakness of tissue account for the whole pathology, and which is therefore often well within the hope of a healthy reversion. Additional light has recently been shed on this subject by a paper published by Dr. Comby in the *Journal de Clinique et de Thérapeutique Infantiles* of July 1st, 1897. The writer's observations have been limited to the study of gastric dilatation during infancy. He finds that at an age when the newly-formed organ might be expected to be fully competent the stomach frequently shows a marked degree of dilatation. In 64 children who died in the Hospital for Sick Children, Paris, this viscus was found to be dilated, its volume varying from 200 c.c. to 310 c.c. In 16 others it was contracted. Dr. Comby explains the former condition as being due to atony produced by an auto-infection by putrescent matters resulting from an improper diet, the latter as an evidence of the refusal of such food by the child, who is consequently starved. He believes that infantile dilatation is by no means always recovered from, and that many cases of a like kind which are discovered only in the adult or the aged have had their true beginning in the earliest months of life. As the best means of treatment besides a suitable diet, he advocates irrigation of the stomach, a catheter being passed along the gullet into the stomach, and this organ repeatedly washed out with fifty or sixty grammes of tepid boiled water or Vichy water. He has never known this method to give rise to any serious inconvenience.

THE GENERAL MEDICAL COUNCIL.

THE committee appointed to consider the Midwives Bill now before Parliament, in pursuance of the request of the Lords of the Privy Council, will meet at the offices of the Council on Monday next, the 26th inst. It is understood that the usual July meeting of the executive committee will not be held in the absence of any urgent business.

CEREBRAL ABSCESS IN CHILDREN.

AT the recent meeting of the American Pediatric Society Dr. Hott gave an account of four cases of this condition which had come under his notice. Details were published in *Pediatrics* of June 1st. The first case was that of a child, aged six weeks, and this has the peculiar interest of being the earliest age at which an intracranial abscess has been described. The child was born easily and naturally and there was no history of injury or disease. It was a fat, healthy-looking infant, with nothing abnormal until four days before death, when swelling of the left thigh commenced. On admission to hospital the child was found to be almost moribund, with a feeble, almost imperceptible pulse, and a temperature of 99·5°F, but without coma. The thigh was incised, but no pus was found, only disorganised blood. The patient died, and examination of the brain revealed an abscess in the parietal lobe, with some recent local meningitis on the inner surface of the dura mater. The abscess cavity was 7 cm. long and 5 cm. deep, and contained two ounces of pus. The only likely source of infection was from the external ears, each of which had been punctured, and the punctures were found covered with dirty fluid encrusted with pus. The second child was three months old. The symptoms developed acutely—viz., irregular shallow respiration, retracted abdomen, and fever. There was also opisthotonos in the last few days and convulsions on the last of all. There was found to be a large abscess of the right parietal lobe, which communicated with the ventricles, and pus was found in the left petrous bone, although there was no discharge from the ear during life. The third patient was also three months old and was said to have been well and strong until seven weeks before, when it fell from the bed on to the floor. Three days later the patient cried out sharply and vomited. On admission to hospital there were emaciation, occasional vomiting, and discharge of blood from the left ear. Death took place suddenly, and there were found to be meningitis of the inferior surface of the cerebellum and an abscess as big as a hazel nut. The fourth case was that of a child nine months old. On admission the patient was found to be in excellent condition as regards nutrition, but there were internal strabismus, dilatation and inactivity of pupils to light, and increased knee-jerks; there was no fever. Vomiting occurred occasionally, and symptoms of irritation alternated with drowsiness. Gradually rigidity developed in the lower extremities and hands, and there were slight paralysis of the left side of the face and discharge of pus from the ear. The child died in the eighth week of the illness, and at the necropsy two abscesses of considerable size were found in the right lateral lobe of the cerebellum. These did not communicate, and no pus was found in the

Digitized by Google

auditory canal. In conclusion Dr. Hott gives a short account of the different conditions in which cerebral abscess occurs in children. It is rare in the first four years of life, more common later, and the first case referred to is the youngest case recorded.

A PROFESSORSHIP OF PUBLIC HEALTH AT LIVERPOOL.

WE notice with pleasure that the Council of University College, Liverpool on the recommendation of the Senate and Medical Faculty, have converted the Medical Lectureship of Hygiene into a Professorship of Public Health, and that the appointment has been given to Dr. E. W. Hope, medical officer of health to the corporation of Liverpool, Lecturer on Hygiene in University College, Liverpool, and Examiner in Public Health in Victoria University, Manchester. The creation of the professorship and the appointment of Dr. Hope are creditable to the authorities of the College. Liverpool long had an unenvlable distinction as the unhealthiest of our largest cities. The steady removal of this scandal is due very largely to the clearness with which Dr. Hope and his predecessor, Dr. Taylor, demonstrated the causes of this high mortality, and to the perseverance with which they urged the Corporation of Liverpool to wage incessant war with the causes of disease which existed in the cellars and other unhealthy dwellings, and with the intemperance and other evil habits of many of its crowded population. The action of the authorities has been rewarded by a large measure of success, so that Liverpool can now boast a lower rate of mortality than other towns the density of the population of which is much less, such as Dublin and Manchester. There is a large decrease in the number of deaths from the principal zymotic diseases. Typhus fever is not so effectually extinguished as in London and Ireland; but according to Dr. Hope's recent report its mortality in 1896 was at the rate of 5·6 per 100,000 of the population, as compared with 132·1, the rate for the decennial period 1866-75. Mortality from tuberculous disease is also being largely reduced. There is still, however, much to be done, and the death-rates from fever, diarrhœa, and measles testify to a large preventable mortality. There can be no better way of securing this than by magnifying the office of the medical officer of health; and this is especially wise when the officer is one so capable as the present occupant of the post.

POSSIBLE EXCEPTION TO COLLES'S LAW.

AT the recent meeting of the American Dermatological Association Dr. Corlett, of Cleveland, recorded an interesting case[1] of great importance, although, unfortunately, not complete and conclusive. He urges that we may look for an occasional exception to this law, which need not necessarily impair its general value as a clinical fact. The case was as follows. A woman applied to the Charity Hospital on account of an extensive eruption on her infant. It was discovered that there was also a suspicious looking lesion on her own breast. The child was two months old, with a dark reddish macular eruption over the entire body, including the palms and soles. Over the buttocks extensive excoriations were present and the infant had snuffles and mucous patches, and was small and shrivelled in appearance. The child had apparently been born at full term and was healthy for three weeks after birth. There seemed to be no doubt that the child was syphilitic. The mother was anæmic and complained of aching in the bones of her legs. There was a sore on the left breast about two inches from the nipple, which had appeared about two weeks after the child's mouth became sore. This sore was a superficial ulcer about the size of a split pea, indurated and with a slight serous discharge. The axillary glands were enlarged, freely moveable, and painless. The post-cervical lymphatic glands were also enlarged, and there was slight redness of the mouth. The skin was free from other scars or eruption, but the sore looked extremely like a primary sore, and there seemed to be a presumption that the infection was from the child. The history of the mother was that she had enjoyed good health and had borne to her first husband two healthy children still living. She had never miscarried. She had been married a second time a year before she came under observation, her second husband having been a widower for three years and having had by his first wife four healthy children. According to his wife's statement he had been under treatment for some disease recently, but he was said to appear well, often, however, taking medicine for a "cold." An effort was made to see the husband, but it was unsuccessful, and the mother and child also disappeared, so that the case is incomplete. But the evidence, such as it is, seems at least to suggest that the cases may illustrate, as some hold, that Colles's law is by no means one without exceptions. It is unfortunate that it was impossible to follow the cases through their subsequent history.

[1] Pediatrics, June 1st, 1897.

ON July 14th H.R.H. Princess Christian laid the foundation-stone of the new cancer wing at the Middlesex Hospital. The new building will accommodate thirty-six female patients who, in the words of the founders of the cancer wards, are never discharged until "relieved by art or released by death."

DR. HERMANN WEBER, the President, will preside at the thirty-ninth annual meeting of the New Sydenham Society at 20, Hanover-square, on Tuesday next, at 4 P.M. All interested in the society, whether members or not, will be welcome at the meeting.

THE *London Gazette* of Tuesday, the 20th inst., announces that the Prince of Wales has been pleased to appoint Sir William Mac Cormac, Bart. (President of the Royal College of Surgeons of England), and Mr. Alfred Downing Fripp (M.S. Lond., F.R.C.S. Eng.), to be Surgeons-in-Ordinary to His Royal Highness.

AT a recent meeting of the council of the British Institute of Preventive Medicine, Dr. Allan Macfadyen was appointed Director of the Institute.

THE *London Gazette* of Friday, July 16th, announces that the dignity of a Knight of the United Kingdom of Great Britain and Ireland has been conferred on Mr. Thomas Naghten Fitzgerald, F.R.C.S. Irel., senior surgeon of Melbourne Hospital.

EDINBURGH DENTAL HOSPITAL AND SCHOOL.—The summer meeting of the Edinburgh Dental Hospital and School was held on the premises in Chambers-street on July 16th, Bailie Sloan presiding. The report for the past session showed that there were at present forty-nine students, twenty-two of whom had been enrolled during the past year. The increasing attention paid to the conservation of the teeth was referred to, and it was stated that the prosthetic possibilities of the cases were carefully observed by the students entrusted with the construction and fitting of the dentures. During the year from July 1st, 1896, there were 6075 conservation cases and 4545 patients underwent operations in the surgical department. The chairman afterwards presented the medals and prizes to the successful students.

The Lancet Special Commission
ON
SICILY
AS A HEALTH RESORT.

IV.[1]

Public Health Questions in Sicily.—Rates of Mortality.—The Amount of "Fever," Malaria, Typhoid, Diphtheria, Dysentery, Diarrhœa, &c.—Rate of Incidence of Respiratory Affections.—Favourable Statistics regarding Phthisis.—Spas and Mineral Springs of Sicily: Termini, Sciacca, Acireale, Sclafani, Barcellona, and Acqua Santa di Palermo.—Sanitation and Water Supply.—Analyses of Waters made in THE LANCET *Laboratory.*

IT would be beyond the scope of these articles to attempt to give an exhaustive account of public health and disease in Sicily. Attention must be limited for the most part to those phases of the subject which affect the suitability of the island as a health resort. Sicily has the reputation of being one of the healthier portions of the Italian kingdom, and this reputation would appear to be well founded. Malaria, though somewhat widely prevalent during the summer months, is not usually of a severe type, and the deaths from this disease per 10,000 inhabitants are given by Dr. Andrew Davidson[2] as 8·4, which may be compared with the figures for Latium (13·2), Calabria (20·4), Campania (2·5), and Sardinia (20 0). "Fever" prevails somewhat extensively, but it is a moot point whether this is usually typhoid fever or the much less serious "Mediterranean fever" or "Malta fever." To this point we shall return, as a definite view upon the subject is indispensable for a correct interpretation of the Sicilian mortality tables. Dysentery, diarrhœa, and diphtheria are relatively somewhat prevalent, while, on the other hand, diseases of the respiratory organs (including pulmonary tuberculosis) are below the European average. Ophthalmic affections are common. Rheumatism is common. Under the other heads of disease there does not appear to be anything characteristic to note. The annual rates of mortality in the principal towns, though somewhat high if tried by the British standard, are moderate for Southern Europe. The rate for Palermo is about 24 5 per 1000, for Catania 28 4 per 1000, and for Syracuse 25·4 per 1000. These figures are calculated from the officially certified number of deaths and probable population, and may be accepted as at least approximately accurate. When it is remembered that there is much poverty in Sicily, and that poverty has a considerable influence upon mortality, and when the higher average mortality in warm as compared with temperate countries is borne in mind, these returns must be regarded as not unfavourable. The general death-rate of the entire kingdom of Italy for the ten years ending 1887 was 28·1 per 1000, so that the Sicilian towns are, on the whole, below the general average. The special questions in this connexion which most directly affect the suitability of Sicily as a health resort are the following: (1) the character and amount of "fever" (including malaria) prevalent in the island; (2) the amount of dysenteric and diarrhœal affections; and (3) the amount of respiratory disease, including phthisis. These questions will now be examined in detail.

1. Visitors to the various Mediterranean sanatoria are familiar with the fact that at most of these resorts there prevails an affection known as "low fever," "coast fever," "continued fever," "Mediterranean fever," "Neapolitan fever," "Malta fever," &c. Surgeon-Colonel Lane Notter defines this disease as "an endemic fever of long duration, accompanied by profuse perspiration and constipation, and often followed by pains of a rheumatic or neuralgic character, swelling of the joints, or orchitis, and tenderness or enlargement of the spleen. The disease is further characterised by a small mortality, tedious convalescence, a constant liability to relapses, and well-marked anæmia. It is not contagious." The question whether this fever is a variety of typhoid fever or distinct from that disease has excited much controversy, but the great preponderance of opinion amongst experts is in favour of the differentiation of the two affections. This is the view upheld by Bruce, Davidson, Hughes, Maclean, Notter, and others. The subject has an important bearing upon the nosology of Sicily, where forms of low continued fever are common. The Sicilian practitioners are by no means agreed as to the proportion of these fevers which should be regarded as Mediterranean fever and as mild typhoid fever. By some genuine typhoid fever is regarded as quite rare in Sicily, while others regard it as common, though usually somewhat mild in its course and favourable in its event. The subject is involved in great obscurity aad is one upon which a difference of opinion is natural and inevitable. Professor L. Giuffrè, of the University of Palermo, gives an opinion that in that city "la febbre tifoidea genuina è molto rara" (genuine typhoid fever is very rare), and in summing up his conclusions in his learned monograph upon "The Continued Fevers observed in Italy from 1872 to 1886" he regards the continued fever common in Sicily as "a definite species absolutely distinct from typhoid fever, and up to a certain point distinct also from the classical "miliary" fever, of which it is in all probability a recent transformation." Professor Cervello, of Palermo, also regards genuine typhoid fever as rare, but this view is not universally held by the Sicilian practitioners, some of whom believe that many of these cases of obscure continued fever are really mild cases of typhoid fever. Turning to the official returns, it appears that at Palermo (where compulsory notification of disease is in force) the number of cases of typhoid fever notified in recent years was as follows:—1893, 76 cases; 1894, 151 cases; 1895, 58 cases; and 1896, 112 cases. The above figures are those officially supplied by the municipality, and they are remarkably low for a city of 280,000 inhabitants. They cannot be reconciled with the statement of Dr. Andrew Davidson,[3] that the average death-rate from typhoid fever per 10,000 living is in Sicily 14·3. There is here a radical discrepancy which can only be explained by assuming that the returns are calculated on different principles. There seems no doubt that typhoid fever is generally very prevalent in Italy. Hirsch[4] remarks that "in Italy, while the deaths from typhoid fever in the army in 1877 were 342, in a general mortality of 2072 among an effective force of 193,650 men, or 1·8 per 1000, the deaths from this disease in the country generally reached the enormous figure of 16·5 per cent. of the total mortality." The true rate of prevalence of typhoid fever in Italy and Sicily must remain doubtful while the nosological relation of that disease to "Mediterranean fever" (the "febbre infettiva" or "febbre innominata" of the Sicilian authorities) remains undetermined, or, at least, disputable. What seems certain is that in the various Sicilian towns there is a large amount of low continued fever—whether mild, typhoid, or Mediterranean fever—but that well-marked typhoid fever of the type familiar to English observers is not common. The facts regarding malarial fever are clearer and less open to controversy. Malaria is widely prevalent in Sicily, but it is not usually of a severe type; it is almost confined to the summer and autumn months; it hardly exists in the large towns except as an importation, and its importance to winter visitors is practically *nil*. Professor Cervello has kindly favoured THE LANCET Commissioner with the following memorandum on the subject: "It is undoubtedly true that there are in Sicily certain localities infected with malaria, but this need not by any means be a danger to strangers who come to pass the winter with us, since the places where they sojourn—such as Palermo, Catania, Acireale, Taormina, &c.—and those to which they pay a passing visit are absolutely exempt from malaria and perfectly healthy. The infected localities are circumscribed and distant from the great centres ..... hence the question of malaria concerns the inhabitants of the island exclusively, and not all of these, but only those who cultivate these infected districts. Further, the malarial fevers occur from the end of June to the beginning of October, a period in which travellers do not come to Sicily." Inquiries made in many parts of Sicily confirmed the above statement, and Dr. Tommasi-Crudeli, of Rome, the well-known authority on malaria, has verbally given the Commissioner his views on malaria in Sicily, and these views do not differ in any material point from those of Professor Cervello. Catania is probably the most malarious commune in Sicily, so that an examination of the figures for Catania will show the worst phase of the island from the point of view of malaria. The average deaths per annum from malaria

[1] Nos. I., II., and III. were published in THE LANCET of June 5th and 12th, and July 3rd, 1897, respectively.

Digitized by Google

in Catania were (1878–1895) 39. It must be remembered that the cases do not arise in the city, but almost without exception come from the Piana di Catania, parts of which are highly malarious in summer and autumn. As regards Palermo Professor Giuffrè writes: "Le febbri di malaria in Palermo non esistono." (Malarial fevers do not exist in Palermo). Cases occasionally arise in marshy land some miles distant from the city, but these are practically confined to the cultivators of the soil. Girgenti, Syracuse, and Taormina are also virtually exempt from malaria, so far as the towns are concerned, although the disease is frequent in their vicinity during summer and autumn. The subject of malaria in Sicily is one of great importance to the inhabitants of the island, and is of much interest to the scientific observer, but it may be affirmed with confidence that it is one with which the invalid visitor has no practical concern. In winter and spring and in the districts frequented by foreigners malaria may be said to have no existence.

2. Dysenteric and diarrhœal affections are, as already stated, common in Sicily, especially in summer and autumn. They are probably due to heat, imperfect sanitation, and the consumption of unwholesome fruit. In Catania the deaths from dysentery (1881–95) averaged 69 per annum, nearly twice as many as the deaths from malaria. It is satisfactory to note that a marked improvement seems to be in progress as regards this disease. Thus the deaths from dysentery, which were 161 in 1881 and 124 in 1882, had fallen to 53 in 1893 and to 35 in 1894. Catania has been improving its water-supply, and the above is the satisfactory result. Diphtheria is somewhat common in the Sicilian towns, and forms one of the chief items in the bills of mortality. The deaths from this disease in Palermo during recent years have been as follows: 1893, 126 deaths; 1894, 305 deaths; 1895, 267 deaths; and 1896, 138 deaths. In Catania the deaths from this disease have averaged (1878–95) 103 per annum, but in the case of diphtheria, as in the case of dysentery, Catania can show a marked improvement in recent years. Thus, the deaths from this cause, which numbered 229 in 1878 and 316 in 1879, had fallen to 29 in 1894 and to 39 in 1895. The disease is one which varies much from year to year, but the progressive improvement is striking and creditable. Although Catania comes so well out of these comparisons, it must be borne in mind that the general mortality there is considerably higher than in Palermo.

3. The subject of the prevalence of respiratory diseases in Sicily is one of great interest and importance, since sufferers from these maladies furnish the chief contingent of those who seek climatic change in winter. The general consensus of opinion among the Sicilian practitioners is that bronchitis and pleurisy are somewhat common, pneumonia not common, and pulmonary tuberculosis common, but below the general European average. Professor G. B. Ughetti's memoir, "Sulla Tubercolosi in Catania," contains much interesting information regarding the prevalence of the last-mentioned disease in Sicily. It would appear that in the year 1878, when the population of Catania was 90,423, the deaths from pulmonary tuberculosis were 120, a rate of 1·32 per 1000 inhabitants. In 1888, when the population of the city had increased to 106,847, the deaths from pulmonary tuberculosis were 127, a rate of 1·18 per 1000. In 1895 the population of Catania was 115,992 and the deaths from pulmonary tuberculosis 144, a rate of 1·24 per 1000. These are remarkable figures, and would tend to show that the rate of prevalence of pulmonary tuberculosis in Catania is far below the ordinary European average. Hirsch, whose authority is not only high, but free from any suspicion of bias in favour of Sicily, gives the rate in Catania as 1·42 per 1000 inhabitants. How very favourably this contrasts with the general average of cities will be apparent from the following table, which is also derived from Hirsch's great work, "Handbook of Geographical and Historical Pathology."

Table showing the death-rates from pulmonary tuberculosis per 1000 inhabitants.

Christiania	3·45	San Francisco	2·97
Stockholm	4·1	Edinburgh	3·0
Copenhagen	3·0	Glasgow	4·0
Berlin	3·8	Geneva	2·2
Leipzig	3·5	Paris	4·1
Dresden	3·8	Milan	3·6
Munich	4·0	Rome	3·42
Cologne	4·4	Naples	2·75
London	3·2	Palermo	2·64
Melbourne	2·2	Algiers	2·9
Boston	3·3	Catania	1·42
New Orleans	3·9		

The table shows how ubiquitous a disease is pulmonary tuberculosis, and also how uniform on the whole are its ravages in the great cities of the world. Professor Ughetti claims for Catania the lowest relative mortality from this disease of any of the Italian and Sicilian cities. He also finds that Sicily as a whole compares very favourably with the Italian kingdom in general, and gives a table to show that the deaths from tuberculosis (pulmonary and meningeal) in Sicily are only about half the average for Liguria, Lombardy, and Tuscany.

The interesting and important subject of the natural mineral and thermal waters of Sicily will now be considered. The geological formation of the country, the wide diffusion of sulphur-producing strata, and the large amount of volcanic activity present conditions which lead the observer to expect numerous spas and mineralised springs, and this expectation is found to be justified. The following list (though probably not exhaustive) comprises the chief thermal and mineral waters of Sicily:—(1) Termini-Imerese; (2) Sciacca; (3) Acireale; (4) Sclafani; (5) Barcellona; and (6) Acqua Santa di Palermo. Full analyses of the majority of these waters have been furnished to THE LANCET Commissioner, but considerations of space compel a somewhat summary treatment of the subject.

1. *Termini-Imerese.*—There are two springs at Termini, known as the South-west spring and the North-east spring. The former is called "salino-alcalino-acidulo-terrosa," and its characters, according to the analysis of Professor Paternò, are briefly as follows. The water is perfectly limpid as it comes from the spring, but becomes turbid after a considerable exposure to the air. It is colourless and odourless, and has a saltish and bitter taste. Its temperature is uniformly 43° C. (= 109·4° F.). Its specific gravity is 1·0119. It slightly reddens blue litmus paper. It does not decolourise a solution of permanganate of potassium. A kilogramme of the water contains: Nitrogen, 0·0168 gramme; oxygen, 0·0011 gramme; carbonic acid, 0·1300 gramme; sulphurous acid, 0·1078 gramme; chlorine, 8·3072 grammes; sodium, 4·6927 grammes; magnesium, 0·3492 gramme; and calcium, 0·5291 gramme. The chlorine is present in the form of sodium chloride, calcium chloride, and magnesium chloride—the first being much the most abundant. A kilogramme contains 0·0166 gramme of free carbonic acid. The north-east spring, according to the analysis of Dr. Oliveri, has the following characters. The water is perfectly limpid and does not become turbid on exposure to the air. The taste is saltish and the reaction neutral. The temperature is 42·50° C. (= 108·5° F.). The specific gravity is 1·011575. The amount of free gas in a litre is 26·60 c.c.—viz., carbonic acid, 12·35 c.c.; nitrogen, 10·05; and oxygen, 4·20. The chief mineral ingredients are chloride of sodium, chloride of potassium, chloride of magnesium, chloride of calcium, bromide of magnesium, sulphate of calcium, sulphate of magnesium, carbonate of calcium, carbonate of magnesium, and silicon. These waters are used both externally and internally, and Dr. Battaglia, the medical director of the baths of Termini, recommends them in the following affections—viz., muscular and articular rheumatism, chronic exudations, remains of inflammatory affections, various neuralgias, peripheral paralysis, some forms of spinal neurasthenia, passive congestion of the liver and spleen following malaria, some forms of gout, chronic adenitis, osteitis, and periostitis.

2. *Sciacca.*—Sciacca is situated on an eminence overlooking the sea upon the western coast of Sicily, and is distant about twenty-four miles from Castelvetrano. It occupies the site of the Thermæ Selinuntinæ of antiquity. The sources of the hot springs are situated in the valley between the town and Monte S. Calogero. The mineral waters of Sciacca are numerous and of varied composition. There is (*a*) a sulphur spring, of which the temperature is from 50° to 52° C. (= 122° to 125·6° F.), and the chief constituents sulphuretted hydrogen and chloride of sodium. A litre of the waters contains 1·5 grammes of the former and 8·026 grammes of the latter ingredient. (*b*) The Acqua Santa of Sciacca, which has a temperature of from 30° to 32° C. (= 86° to 89·6° F.), and of which the composition closely resembles the mineral waters of Vichy and of Casamicciola. The free carbonic acid present in a litre of this water amounts to a gramme, and fifty-eight centigrammes carbonate of iron to twenty-three centigrammes and chloride of lithium to 0·31 gramme. (*c*) The Acqua Ferrata of Sciacca, which has a temperature of 28° C. (= 82·4° F.), and which is very rich in bicarbonate of iron, a litre of the water containing

Digitized by Google

eighty-three centigrammes of this salt. It also contains a considerable amount of free carbonic acid. The vapour baths of S. Calogero, which are close at hand, add to the extensive resources of Sciacca. The temperature of the vapour in these grottoes varies from 36° to 42° C. (= 96·8° to 107·6° F.).

3. *Acireale.*—Acireale rests upon the lava streams of Mount Etna, at an elevation of 560 ft. above the sea-level and distant about nine miles from Catania. The waters (Terme di Santa Venera) are not thermal. The gases present in the waters in the free state include sulphuretted hydrogen (10·508 c.c. per litre), carbonic anhydride (95·704 c c. per litre), oxygen, and nitrogen. The chief mineral ingredients are chloride of sodium (2 68466 grammes per litre), sulphide of sodium, chloride of potassium, chloride of magnesium, chloride of lithium, iodide of sodium, carbonate of calcium, carbonate of magnesium, manganese, and silica. The climate of Acireale resembles that of Catania, but its greater elevation gives it some advantage. The late Professor Cantani, of Naples, who esteemed Acireale very highly, attached great importance to the fact that the town being built upon the "terreno vulcanico" had a very dry soil, while the humidity of the air was moderate, thus ensuring equability of temperature. The mineral waters of Sclafani, Barcellona, and Acqua Santa of Palermo are of less importance.

It will thus be seen that the resources of Sicily in spas and mineral springs are ample and varied; they have not, however, been developed in any thorough or systematic way. The bathing arrangements and hotel accommodation are good at Termini and Acireale, fair at Barcellona, elsewhere mediocre. The bathing season, as generally in Europe, is from the end of spring to the beginning of autumn.

The important subject of the potable waters of Sicily may fitly conclude this article. The Sicilian towns have been making great progress during recent years as regards their water-supply. Public interest has been aroused in the subject, which, it need hardly be said, is one of the first importance both to the inhabitants of the island and to tourists and invalids. Palermo has recently introduced an admirable water (the "Scillato") from sources in the Madonian Mountains seventy kilometres from the city. It has also other sources of supply showing a high degree of purity. Marsala has recently introduced a new water-supply. The water-supply of Girgenti is limited in amount, and, on the whole, defective in quality; but the spring from which the sample examined in THE LANCET Laboratory was drawn shows an admirable degree of purity. Professor Ughetti certifies that the water-supply of Catania is "good and sufficient." Taormina has a very limited water-supply, but the quality is good.

It has been pointed out that the Sicilian towns have shown considerable enterprise in improving their water-supplies, and the analyses made in THE LANCET Laboratory show that this enterprise has had its reward. It cannot, however, be affirmed that they have made equal progress as regards drainage, cleansing of streets and harbours, &c. Most of the towns have a very antiquated system of drainage, the soil is in many cases much impregnated with organic refuse material, the outfall is in close proximity to residential quarters, and the almost tideless Mediterranean increases the difficulty of disposing satisfactorily of sewage matters The flushing of the sewers is done somewhat imperfectly and intermittently. The cleansing of the streets is not effected in any thorough or efficient manner, decaying vegetable matter and various kinds of garbage being freely exposed to the powerful rays of a southern sun. In all these respects much work remains to be done to render the sanitary condition of Sicily satisfactory. The energy shown in providing new sources of water-supply encourages the hope that in time sanitation will be dealt with in a like spirit. The results of the analyses of the samples of Sicilian waters forwarded to THE LANCET Laboratory are appended.

THE LANCET ANALYSIS OF SICILY WATERS.

The samples were received on June 15th at THE LANCET Laboratory, where they were submitted to chemical examination and analysis at some length. In all eight specimens were examined. Of these seven were distinctively labeled, while the eighth sample was unlabeled. The stopper of the ninth sample had evidently become detached, since there were not more than a few ounces of water in the bottle. This sample and the eighth are, therefore, omitted from the list. The waters were contained in clean, colourless, stoppered bottles of about two litres capacity. The stoppers were tied down and covered with a leather cap and sealed. The results of analyses, expressed in grains per gallon, together with other observations, were as follows:—

SAMPLE 1.—*Scillato Serpatoio S. Ciro.*

Appearance	Clear, bright; no deposit.
Colour	Faintly blue.
Odour	None.
Total solid matter	16·80
Change on ignition of solids	None.
Total hardness	11·20.
Chlorine	1·05.
Equal to common salt	1·73.
Nitrogen in nitrites	0·050.
Nitrogen in nitrates	None.
Free ammonia	None.
Albuminoid ammonia	None.
Oxygen absorbed in fifteen minutes	0·0018.
Oxygen absorbed in four hours	0·023.
Reaction	Slightly alkaline.

This is a sample of the new water-supply recently introduced into Palermo. The catchment area is at Scillato in the Madonian mountains 70 kilometres from Palermo. The S. Ciro reservoir is within three or four miles of Palermo and is a service reservoir. The soil of the catchment area is composed of secondary calcareous rocks. The temperature of the water in the basin at Scillato was 54·2° F., and of the air 57° F. The water shows that admirable organic purity characteristic of water derived from an uncontaminated chalky area. The mineral matter in solution consisted almost entirely of lime salts. The water is practically free from nitrogen either in mineral or organic form. It contained absolutely no free ammonia and yielded no ammonia (albuminoid) on boiling with alkaline permanganate; neither did it abstract oxygen to any appreciable extent when mixed with a weak solution of acidified permanganate. The water is irreproachable in quality.

SAMPLE 2.—*Acqua del Gabriele, from the Piazza Sant Annuzza.*

Appearance	Bright, no deposit.
Colour	Slightly blue.
Odour	None.
Total solid matter	27·3.
Change on ignition of solids	None.
Total hardness	19·68.
Chlorine	1 69.
Equal to common salt	2·78.
Nitrogen in nitrates	0 252.
Nitrogen in nitrites	None.
Free ammonia	None.
Albuminoid ammonia	None.
Oxygen absorbed in fifteen minutes	0·0046.
Oxygen absorbed in four hours	0·022.
Reaction	Slightly alkaline.

This is the "Gabriele" water of Palermo collected from a fountain in the Piazza Sant Annuzza in the city. The catchment-area is a few miles from Palermo, and the geological formation of the soil is triassic. The temperature of the water was 55·7° F., and of the air four degrees higher. Like the previous sample this water shows again a very remarkable degree of organic purity. The presence of an increased proportion of nitrates is noteworthy, but the amount, taking into consideration the environment of the water, presents no objection from a sanitary point of view. In considering other results—as, for example, those showing the complete absence of free ammonia or of organic nitrogen or any oxygen-absorbing capacity and of the source of the water—there can be little doubt of its freedom from any source of impurity. It contains more solid matter than the previous sample, which is to be attributed chiefly to the increase of lime salts. The quality of the water for drinking purposes is excellent.

Digitized by Google

SAMPLE 3.—*Sorgina Girgentis.*

Appearance	Brilliant, no deposit.
Colour	Slightly blue.
Odour	None.
Total solid matter	25·9.
Change on ignition of solids	None.
Total hardness	18·42.
Chlorine	1·82.
Equal to common salt	3·00.
Nitrogen in nitrates	0·252.
Nitrogen in nitrites	None.
Free ammonia	None.
Albuminoid ammonia	None.
Oxygen absorbed in fifteen minutes	0·008.
Oxygen absorbed in four hours	0·017.
Reaction	Slightly alkaline.
Metals	No trace.

This is a sample of water derived from a spring at Girgenti. The soil is pliocene. The temperature of the water at the time of collection was 56·4° F., and the air one degree higher. The water shows a chemical composition very similar to Sample 2. Its organic purity is, again, a feature. This is evident from the insignificant or practically negative results reported under chlorine, nitrates, free ammonia, albuminoid ammonia, and oxygen absorbed, and the fact that the residue on evaporation remained unchanged on heating. In respect of organic purity, as well also as in chemical composition, the water somewhat closely resembles the composition of the well-known pure waters derived from the deep chalk wells in Kent.

SAMPLE 4.—*Acqua di Scillato, from the Piazza di Cupo.*

Appearance	Quite brilliant.
Colour	A blue tinge.
Odour	None.
Total solid matter	15·4.
Change on ignition of solids	None.
Total hardness	11·8.
Chlorine	0·91.
Equal to common salt	1 50
Nitrogen in nitrates	0·056.
Nitrogen in nitrites	None.
Free ammonia	None.
Albuminoid ammonia	None.
Oxygen absorbed in fifteen minutes	0·007.
Oxygen absorbed in four hours	0 011.
Reaction	Slightly alkaline.
Metals	No trace.

This is another specimen of the Scillato water drawn from a fountain in one of the squares of Palermo, and, as will be seen, its composition differs but little from Sample 1, which is derived from the same source. These results are all the more satisfactory in showing that there is absolutely no exposure to objectionable contamination along the line of conduits. The high standard of purity is still maintained.

SAMPLE 5.—*Acqua Maurigi, from the Fonte nel Cortile Cascino.*

Appearance	Quite bright.
Colour	Slight blue.
Odour	None.
Total solid matter	23·8
Change on ignition of solids	None.
Total hardness	16 90.
Chlorine	2 31.
Equal to common salt	3 80.
Nitrogen in nitrates	0 252.
Nitrogen in nitrites	None.
Free ammonia	None.
Albuminoid ammonia	None.
Oxygen absorbed in fifteen minutes	0·005.
Oxygen absorbed in four hours	0·009.
Reaction	Slightly alkaline.
Metals	No trace.

This is a specimen of the Maurigi water, another of the Palermo potable waters. The specimen was drawn from a fountain in the city. Like the previous samples of potable water the results give not the faintest evidence of the presence of organic matter. Its composition is closely allied to Sample 2 except that there is a slight, but unimportant, increase in the amount of chloride. The relative proximity to the sea-border may probably account for this small difference.

SAMPLE 6.—*Acqua Corrao.*

Appearance	Brilliant, no deposit.
Colour	Faint blue.
Odour	None.
Total solid matter	28·0.
Change on ignition of solids	None.
Total hardness	18·68.
Chlorine	1·82.
Equal to common salt	3·00.
Nitrogen in nitrates	0 280
Nitrogen in nitrites	None.
Free ammonia	None.
Albuminoid ammonia	None.
Oxygen absorbed in fifteen minutes	0·009.
Oxygen absorbed in four hours	0 015.
Reaction	Slightly alkaline.
Metals	No trace.

This is another of the Palermo potable waters. The specimen was derived from a fountain in the city supplied from the Corrao reservoir. The catchment area is composed of calcareous rocks. The temperature of the water at the time of collection was 64·2° F. As might be expected, considering the nature of the area from which this water is collected, it shows a somewhat high proportion of mineral matters—in fact, the highest of the series—with a correspondingly increased degree of hardness due to chalk removable on boiling. In character it resembles Sample 3, some of the results being identical. The nitrates, however, are slightly increased. There is not a particle of evidence in the analysis that the water sustains the slightest pollution at any point.

SAMPLE 7.—*Acqua Santa.*

Appearance	Bright and clear.
Colour	Slight green.
Odour	None.
Total solid matter	1291·5.
Change on ignition of solids	None observable.
Total hardness	—
Chlorine	652·4.
Equal to common salt	1075·1.
Nitrogen in nitrates	0·056.
Nitrogen in nitrites	None.
Free ammonia	Trace.
Albuminoid ammonia	0·0084.
Oxygen absorbed in fifteen minutes	0·008.
Oxygen absorbed in four hours	0·022.
Reaction	Distinctly alkaline.
Metals	No trace.

This is a mineral water, as is obvious from the analysis, which has its source in the environs of Palermo and arises in a grotto. It possesses a strong saline taste. The temperature varies from 64 4° to 66·2° F. The results show a high standard of organic purity. Its saline strength is about half that of sea-water, the constituents being similar. In addition to common salt it contains also important quantities of sulphate of lime and magnesia, while a distinct indication of lithium was afforded on examination of the residue by spectroscopic analysis.

To sum up, it is evident that the potable waters of Sicily submitted to us for examination show an exceptional purity. In not a single sample of water examined could any evidence be traced of organic impurity. It is remarkable also that the whole of the drinking waters with not one exception yielded absolutely no free ammonia, or even ammonia when boiled with alkaline permanganate. As is well known, any nitrogen present in an organic form, as in the form of albuminoid, is converted into ammonia on heating with a solution of permanganate of potash and caustic alkali. Under the heading of albuminoid ammonia in the foregoing results it will be observed that the satisfactory result, "none," is recorded all through the series. In the same way the

Digitized by Google

complete absence of organic matter is shown in the results coming under the heading of "oxygen absorbed." In every instance the amount was insignificant and quite negligible. Again, the residues obtained on evaporation showed not the least sign in any single instance of charring, so that not only is the presence of animal matter excluded, but also that of vegetable matter. The waters were clear and bright, fresh to the taste, and well oxygenated. According to the evidence furnished in the foregoing results these potable waters of Sicily are admirable in excellence and purity.

MEDICAL AID ASSOCIATIONS AND THE NORWICH MEMORIAL.

A MEETING of the medical profession in Norwich was held on the 17th inst., Sir Frederick Bateman, consulting physician to the Norfolk and Norwich Hospital, being in the chair, to consider replies from the Royal Colleges of Physicians of London and Surgeons of England (already given in THE LANCET) and from the Council of the British Medical Association, in answer to a memorial addressed to these bodies with regard to a medical institute and consultations with the medical officers thereof. The following resolutions were unanimously passed:—

1. *Royal College of Physicians of London.*

"That whilst the thanks of this meeting be given to the Council of the Royal College of Physicians for their reply to the memorial, the medical men of Norwich desire to express the hope that the College will in due course so alter its By-laws that it would not be considered 'a departure from its customary procedure' to forbid its Fellows, Members, and Licentiates from accepting positions derogatory to the honour and contrary to the best interests of the profession."

2. *Royal College of Surgeons of England.*

"That this meeting, whilst acknowledging with thanks the reception of their deputation and the reply of the Council of the College of Surgeons to the memorial, desire to express an opinion that steps should be taken so to amend Section XVI. of the College By-laws as to enable the Council to prevent its Fellows and Members accepting positions derogatory to the honour and contrary to the best interests of the profession."

3. *British Medical Association.*

"That a vote of thanks be accorded to the Council of the British Medical Association for so far answering their memorial in undertaking to memorialise the Medical Council to take further steps to prevent the growing evils of medical aid associations, but that this meeting regrets that the Council of the B.M.A. declines to give an answer to that part of the memorial which referred to consultations with the medical officers of these trading societies."

General Council of Medical Education and Registration.—The secretary reported that the memorial had been acknowledged by the Medical Council, but no reply had been received.

The Royal College of Physicians of Ireland passed the following resolution on Nov. 3rd, 1893, and confirmed it by a subsequent resolution of May 28th, 1897:—

"That the Royal College of Physicians, Ireland, desire to express their disapproval of their Licentiates accepting office in medical aid associations as at present conducted in England, inasmuch as the independence of the physician is destroyed by the system and the services of the physicians are used so as to produce a profit for lay persons, &c."

It was unanimously resolved that no further steps be taken with regard to meeting the medical officers of the Norwich Institute in consultation, as this had been decided by a large meeting of the profession (33) held on Jan. 16th, and subsequently endorsed by the signature of forty-one medical men in the city of Norwich.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

DELAY AT HEAD-QUARTERS.

AS was indicated in our columns last week, the organizers at headquarters are not beforehand with their arrangements for their visitors. We have heard from several gentlemen who have sent their cheques that they have not been credited with the full amount of roubles necessary to become members, and that not having received their railway passes they remain in ignorance if these are being withheld because of incomplete payment or because the passes are not ready for distribution.

Mr. Makins, upon whom has devolved the practical work of the English Committee, tells us in another column that he has learned from Professor Roth that cheques for £1 are received in full discharge of the fee of membership, and that the free railway tickets are in active course of preparation—so that we can only preach counsels of patience.

We have been asked by Professor Roth to announce to our readers that the free railway tickets will not be available till after Aug. 1st, and the Secretary-General repeats his request for early information from members as to the frontier town at which they intend to arrive. This information should be sent to the Secretary-General before Aug. 1st, and we may add that for the purposes of these passes St. Petersburg is to be considered a frontier town.

The English Committee is now issuing the following letter to such intending members as have entered into correspondence with that Committee:—

International Medical Congress,
47, Charles-street, Berkeley-square, London, W.,
July 19th, 1897.

DEAR SIR,—As it appears possible that the delay in the receipt of tickets and certificates for the journey to Moscow may in some cases be due to defective fulfilment of the "conditions de voyage en Russie" laid down on pages 6 and 7 of the pamphlet "Renseignements divers," previously sent to you, the English Committee has prepared the form at the back, which should be torn off, filled up, and sent at once to Professor W. K. Roth, Secrétariat Général du XII. Congrès International de Médecine, Moscow.

If no acknowledgement of your cheque has been received the form can be altered to meet the case.

May I take this opportunity of pointing out that the English Committee is an honorary body and not a part of the Executive of the Congress, hence all questions regarding the business of the Congress, or relating to excursions, lodging, accommodation, &c., must be sent direct to the Secretary-General (in the case of lodgings to Professor Chervinsky, care of Secretary-General).

Yours faithfully,
G. H. MAKINS.

On the back of this letter is printed the following form:—

DEAR SIR,—I beg to inform you that I sent my subscription to the Congress last, and have received from you a post-card acknowledging the same.

I intend travelling to Moscow viâ (*here state route chosen*)

.....

entering Russia by (*here state frontier town of entry*)

.....

and leave by (*here state frontier town on return journey*)

.....

and I shall be much obliged by your forwarding the necessary tickets and certificates at your earliest convenience.

Name.....

Address.....

N.B.—The route chosen must be a direct one from the frontier to Moscow, and *vice versâ*. See "Renseignements divers," p. 7.

A FEW HINTS.

Intending visitors to Russia will do well to remember the following points:—1. A passport is absolutely necessary, for no one can enter Russia without one. 2. Any traveller staying in a hotel or an inn must hand over his passport to the landlord, to be by him passed on to the police. This and the following regulation hold good for every town visited. 3. If he is staying in a private house he must himself take his passport to the nearest police office. 4. Permission must be obtained to leave the country as well as to enter it.

Digitized by Google

5. Travelling in Russia is just as easy as anywhere else, provided the traveller conforms to the customs of the country and the police regulations, which are not irksome.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE continue below our record of some of the principal amounts received at the Mansion House, the lists of which have been forwarded to THE LANCET office. The total sum now amounts to over £37,000:—

	£	s.	d.
The Very Rev. the Chief Rabbi, from London Synagogues including—	1259	16	9
Great Synagogue	507	9	6

THE EARTHQUAKE IN INDIA.

THE Anglo-Indian papers contain, as might be expected, a good deal about the late earthquake in India, but full details of the disaster had not been received by them at the date of publication. The issue of some of the journals published in Calcutta must have been a matter of much difficulty and have given rise to a good deal of strain under the circumstances. The shock in Calcutta was the most severe that has been known to the oldest residents. The office of our contemporary, the *Indian Lancet*, for example, suffered severely. "Though a large two-storied building," we are told, "it rocked as if made of cardboard, and we expected it every moment to collapse. The whole building, as a result, has been very severely damaged, and it is with a great effort that the paper is being issued on due date."

The damage done to property has been considerable; indeed, there is scarcely a house that has escaped entirely. The *Indian Medical Record* of June 16th says that the scare in Dharamtala-street, where its office is situated, was one of intense excitement. The Medical College Hospital suffered seriously, and the panic among the patients was almost indescribable. The *Indian Medical Record* states that "most of the patients rushed out of doors, but some of the hospital staff with exemplary courage remained with those who were unable to move. It was some time after the shock before the terrified patients could be persuaded to return to their beds. There are some bad cracks in the walls and over the archways. The second surgeon's ward has suffered most. In the south verandah of the hospital the massive pillars are cracked to a dangerous extent. The Calcutta General Hospital has also suffered a good deal. The two ends of the structure are badly damaged, while the centre hall, set apart for some of the European patients, is in a dangerous condition. The patients have been removed from the hall to other quarters. One European patient named Clive, an actor by profession, had a narrow escape. He is suffering from enteric fever, and was lying unconscious at the time in a special ward, the walls of which were observed by his servant, who was with him, to crack. The man lifted his master out of bed, and just as he emerged from the room the walls caved in. It is reported that some, if not all, of the wards intended for the use of female patients and children cannot be availed of just now."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Friern Barnet Urban District.—Mr. Hugh Stott calls attention, in his annual report for 1896, to a case of enteric fever which was, he considers, caused by the consumption of oysters at Southend. The person in question, a hospital nurse, visited Southend with two friends, and all consumed oysters. A short time afterwards all three were attacked with diarrhœa and vomiting, and the nurse subsequently developed enteric fever. Mr. Stott communicated with the medical officer of health of Southend, but no other cases of enteric fever could be traced to this source. It appears from a report that has recently reached us, that the oyster merchants at Southend have so fully recognised the danger to which certain "layings" on the Southend foreshore were exposed that they have removed the oysters therefrom. It may be remarked that instances of vomiting and diarrhœa after the consumption of oysters are by no means rare, and in certain cases some of those thus affected have subsequently developed enteric fever.

Wigan Urban District.—The county borough of Wigan has not hitherto deemed an annual report from its medical officer of health a necessity, and has apparently contented itself with monthly reports. We are glad to see that the borough has now fallen into line, and we shall look forward to some interesting reports from Mr. William Berry, the present medical officer of health. The Wigan guardians, like many others, during the epidemic of small-pox at Gloucester, decided, at the earnest request of Mr. Berry, to enforce the Vaccination Acts; and it is to be hoped that they will have the courage to continue their enforcement now that the Gloucester "scare" has passed away. It is, however, a sad satire upon the whole system that those responsible for the administration of the Acts should have needed to be stirred into activity by the sanitary authority. Mr. Berry has, too, we note, prevailed upon the sanitary committee to adopt the compulsory notification of measles for three years. Wigan, or at least certain parts of it, still affords, it seems, a suitable nidus for typhus fever, and during 1896 twenty cases with seven deaths occurred.

Hull and Goole Port District.—Dr. J. Wright Mason draws attention in his current report to the necessity in new vessels of increased cubic space for the seamen, of covering the iron work so as to prevent sweating, of the provision of proper lavatory accommodation, and for the placing of berths further away from the sides of the vessels. Dr. Mason thinks that much good might be accomplished in regard to existing vessels if there were more uniformity among port sanitary officials in the several ports of Great Britain. Special attention was given during the past year to vessels from India, 15 having arrived from Bombay and 7 from Kurrachee.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6608 births and 3501 deaths were registered during the week ending July 17th. The annual rate of mortality in these towns, which had been 14·7 and 15·1 per 1000 in the two preceding weeks, further rose last week to 16·6. In London the rate was 16·3 per 1000, while it averaged 16·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 11·2 in Croydon, 11·4 in Halifax, 11·6 in Derby, and 11·7 in Bristol; the highest rates were 23·5 in Salford, 24·2 in Sunderland, 24·5 in Wolverhampton, and 32·2 in Preston. The 3501 deaths in these towns included 572 which were referred to the principal zymotic diseases, against 409 and 504

Digitized by Google

in the two preceding weeks; of these, 244 resulted from diarrhœa, 147 from measles, 73 from whooping-cough, 52 from diphtheria, 32 from scarlet fever, 23 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Croydon, Brighton, Blackburn, and Bradford; and the highest rates in Manchester, Burnley, Salford, and Preston. The greatest mortality from measles occurred in Birmingham, Birkenhead, Manchester, Salford, Burnley, and Preston; from whooping-cough in Salford and Huddersfield; and from diarrhœa in Plymouth, Bolton, Leicester, Sheffield, Liverpool, and Wolverhampton. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 52 deaths from diphtheria included 36 in London, and 4 in Birmingham. One fatal case of small-pox was registered in Hull, but not one in any other of the thirty-three large towns, and there were no cases of small-pox under treatment during last week in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospitals at the end of the week was 2903, against numbers increasing from 2380 to 2885 on the eleven preceding Saturdays; 381 new cases were admitted during the week, against 267, 310, and 349 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 127 and 116 in the two preceding weeks, rose again last week to 138, but were 51 below the corrected average. The causes of 28, or 0·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Manchester, Bradford, Newcastle-upon-Tyne, and in seventeen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4 and 17·7 per 1000 in the two preceding weeks, rose again to 17·9 during the week ending July 17th, and exceeded by 1·3 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·8 in Aberdeen and 15·6 in Glasgow to 24·9 in Leith and 32·4 in Perth. The 534 deaths in these towns included 34 which were referred to diarrhœa, 23 to whooping-cough, 12 to measles, 7 to scarlet fever, 3 to "fever," and 1 to diphtheria. In all, 80 deaths resulted from these principal zymotic diseases, against 69 and 82 in the two preceding weeks. These 80 deaths were equal to an annual rate of 2·7 per 1000, which corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The 34 fatal cases of diarrhœa showed a further increase upon the numbers recorded in recent weeks, and included 15 in Glasgow and 6 in Dundee. The deaths referred to whooping-cough, which had been 16 and 20 in the two preceding weeks, further rose to 23 last week, of which 12 occurred in Glasgow and 5 in Edinburgh. The 12 fatal cases of measles showed a further decline from recent weekly numbers, and included 6 in Edinburgh and 6 in Leith. The 7 deaths from scarlet fever corresponded with the number recorded in the preceding week, and included 3 in Aberdeen and 2 in Glasgow. The 3 fatal cases of "fever" were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 104 and 69 in the two preceding weeks, were 68 last week, and were 16 below the number in the corresponding week of last year. The causes of 43, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·3 and 21·6 per 1000 in the two preceding weeks, further fell to 24·2 during the week ending July 17th. During the thirteen weeks of last quarter the death-rate in the city averaged 27·3 per 1000, the rate during the same period being 15·5 in London and 24·9 in Edinburgh. The 162 deaths registered in Dublin during the week under notice showed an increase of 17 upon the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 11 and 9 in the two preceding weeks; of these, 4 resulted from "fever," 3 from whooping-cough, 2 from diarrhœa, 1 from measles, and 1 from scarlet fever. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 2·8 in London and 2·7 in Edinburgh. The 4 deaths referred to "fever" exceeded the number recorded in any week since March last. The 3 fatal cases of whooping-cough showed a further increase upon the numbers returned in recent weeks, while the mortality from scarlet fever and from diarrhœa corresponded with that recorded in the preceding week. The 162 deaths in Dublin last week included 26 of infants under one year of age, and 38 of persons aged upwards of sixty years; the deaths of infants showed a slight further decline, while those of elderly persons showed a further increase upon recent weekly numbers. Seven inquest cases and 4 deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of 16, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN JOHN D. FERGUSON and Surgeon-Captain George S. McLoughlin are seconded for service in East Africa. Surgeon-Major Patrick J. Nealon, M.D., is placed on temporary half-pay on account of ill-health.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant Cochrane is reported to have passed the required examination in Urdu. Surgeon-Captain W. C. Sprague is appointed to act as Civil Surgeon, Karwar. Surgeon-Major J. P. Barry, on relief, is appointed to act as Superintendent of the Lunatic Asylum, Colaba. Surgeon-Captain J. L. T. Jones, on relief by Surgeon-Major A. W. F. Street, is appointed to take over the duties in Poona performed at present by Surgeon-Major J. P. Barry and Surgeon-Captain W. W. O. Beveridge. Surgeon-Captain A. E. Berry is appointed to the Officiating Medical Charge of the 4th Madras Pioneers. Surgeon-Captain A. W. Dawson, on plague duty, has been transferred from Lucknow to Hardwar in the Saharanpur District, and Surgeon-Captain J. F. Kelly, on plague duty, has been transferred from Hardwar in the Saharanpur District to Lucknow. The services of Surgeon-Captain C. D'Alton, A.M.S., and Surgeon-Captain J. F. M. Kelly, A.M.S., are replaced at the disposal of the Government of India, Home Department. Surgeon-Captain Jay Gould has been appointed an additional Health Officer of the Port of Calcutta. Dr. C. Banks, Superintendent of Emigration, has been appointed an additional Health Officer of the Port of Calcutta in addition to his own duties. Surgeon-Captain D. R. Hamilton, A.M.S., has been appointed to have charge of the Civil Medical duties at Dum Dum, in addition to his own duties, during the absence on leave of Surgeon-Captain M. Morphew, or until further orders. Surgeon-Captain H. A. Stalkartt, A.M.S., has been appointed to have Medical Charge of the Civil Station of Dinapore in addition to his own duties, vice Surgeon-Captain B. K. Basu, transferred.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Staff Surgeons: J. C. F. Whicher to the *Scout*; H. J. McC. Todd to the *Caledonia*; and J. R. McDonald, M.D., to the *Flora*. Surgeons: H. St. D. Griffiths to the *Barrosa*, and for charge of the *Flood* on the way out; G. McGregor to the *Vernon*; and O. Rees, M.D., to the *Pembroke*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain John P. Atkinson, M.D., and Surgeon-Captain John P. Massingham to be Surgeon-Majors.

MEDICAL STAFF CORPS.

A concert was given by the detachment of the Medical Staff Corps at the Station Hospital, Gibraltar, in commemoration of Her Majesty's Diamond Jubilee by permission of His Excellency the Governor and the Principal Medical Officer, Surgeon-Colonel Catherwood. The stage was erected in the patio of the hospital, and over it was displayed a picture of Her Majesty illuminated by lamps. The convalescent patients were allowed to attend the concert, a privilege which was much appreciated.—No. 9 Bearer Company and No. 4 Field Hospital, made up to war strength, assembled at the Curragh Camp on the 13th inst. for field training. The

Digitized by Google

Bearer Company is commanded by Surgeon-Major J. Grove Crofts, the officers for duty being Surgeon-Captains J. S. Green and V. Davoren. The Field Hospital is under the command of Surgeon-Lieutenant-Colonel J. C. Dorman, Surgeon-Majors R. D. Donaldson and H. A. Haines, Surgeon-Captain E. G. Browne being one of the duty officers.—The annual sports of No. 12 Company (Woolwich) were held on the 8th inst. at Charlton-park, and included corps competitions illustrating the various modes of dressing and removing the wounded on the battle-field. Among the company present were Surgeon-Major-General and Mrs. Jameson, Surgeon-Colonel and Mrs. Ferguson, Brigade-Surgeon-Lieutenant-Colonel and Mrs. Fawcett, Brigade-Surgeon-Lieutenant-Colonel Allin, Colonel Yorke, R.A., and many other officers of the garrison. Surgeon-Major Bedford acted as judge in the corps competitions. At the close of the meeting the prizes were distributed by Mrs. Fawcett.

VOLUNTEER CORPS.

Artillery: 1st Norfolk (Eastern Division, Royal Artillery): Surgeon-Lieutenant S. W. Woollett to be Surgeon-Captain. 1st Ayrshire and Galloway: Thomas Easton, M.D., to be Surgeon-Lieutenant. *Royal Engineers* (Volunteers): 1st Lanarkshire: Surgeon-Captain A. Mechan, M.B., to be Surgeon-Major. *Rifle:* 3rd Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon-Lieutenant A. W. Dalby to be Surgeon-Captain. 5th Volunteer Battalion the South Wales Borderers: Charles Evan Humphreys, gent., to be Surgeon-Lieutenant. 1st Nottinghamshire (Robin Hood): Robert Plenderleith Shearer, M.B., to be Surgeon-Lieutenant. 22nd Middlesex (Central London Rangers): Surgeon-Lieutenant G. Herschell, M.D., to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Woolwich Company: Thomas William Bartlett, gent., to be Surgeon-Lieutenant.

DEATH OF SURGEON REGINALD JAMES FYFFE, R.N.

Surgeon R. J. Fyffe, M.R.C.S. Eng., L.R.C.P. Lond., of H.M.S. *Rattler*, died under distressing circumstances on July 12th, at the early age of thirty years. The deceased had only recently returned from the China station, on leave, to be present at the naval review, his home being at Southsea. On July 10th he went to Bratton, near Westbury (Wilts), to his brother-in-law, the Rev. R. S. Jacobs, the vicar. The deceased was riding a bicycle on July 12th to Trowbridge, when he was seen to fall off the machine, and it is surmised that he missed the pedal, which caused the accident. Mr. Fyffe was picked up in an unconscious state, from which he never recovered, and died about eleven o'clock the same evening. At the inquest evidence showed that he had sustained a fracture of the skull, and a verdict of accidental death was returned. Much sympathy is felt in the district at the death of so promising an officer.

A vacancy in the list of Honorary Physicians to the Queen has been filled by the appointment of Surgeon-Major-General William Roche Rice, M.D., C.S.I., late chief of the Indian Medical Department, Sanitary Commissioner with the Government of India, and in earlier years Chief Inspector of Hospitals in the North-West Provinces and Oudh. He joined the service in November, 1856, and has the medal for the Indian Mutiny.

Correspondence.

"Audi alteram partem."

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

To the Editors of THE LANCET.

SIRS,—I have to-day received a letter from Professor Roth in which he states (*a*) that cheques of £1 are received in full discharge of the membership subscription; (*b*) that the preparation of the free railway tickets in Russia and the *cartes de legitimation* is in active progress, but that delay is occurring from the want of exact information from members as to the route chosen by them in entering and leaving Russia; and (*c*) that in a few days a fresh supply of the pamphlet "Renseignements divers" will arrive. To meet the second difficulty a small form, to be sent at once to Professor Roth, has been prepared and issued to every member who has received his form of inscription from me, and copies of this form will be issued to anyone requiring them. I am, Sirs, yours faithfully,

G. H. MAKINS.

47, Charles-street, Berkeley-square, W., July 19th, 1897.

"CYCLING FOR WOMEN: ITS EFFECTS ON PARTURITION."

To the Editors of THE LANCET.

SIRS,—The opinion given by Mr. J. W. McVitie in THE LANCET of July 3rd as to the effect of bicycle exercise on parturition seems to be rashly gratuitous when only based on observations that have been made on two cases; but, more than this, it is one that may be calculated to arouse some misgiving, and even fear, in a section that is very largely represented in cycledom. Such an idea may go far towards casting into disrepute a form of exercise that is now universally recognised as being of very considerable value. The evidence upon which Mr. McVitie bases his conclusions is, indeed, slender—if he is not altogether mistaken about his instances. In the first place, primiparous cases almost invariably exhibit delay during the second stage of labour, whether they be cyclists or not, and therefore it would seem almost absurd for such cases to be taken for the purpose of advancing an alarming theory. But your correspondent exposes himself to controversion on a point of simple physical and physiological effect. The long-continued or oft-repeated pressure of a saddle would not render the perineum "unusually tough and unyielding." To argue that it would do so is merely to indulge in hasty speculation. If the pressure were sufficient to cause an amount of perineal muscular inaction, then the result would be the very opposite to that complained of; there would be atony and want of resiliency, instead of tone and increased resistance. And, on the other hand, if the movement of the perineum on the saddle exercised the muscles to the extent of an over-development of them, then, other things being equal, if the parturient cases were "of good physique" and had the ordinary expulsive forces unimpaired no unusual opposition to the passage of the child would be encountered. Instances go to show that the higher the muscular development the more perfect is any function that is concerned. Savages go through child-birth with much greater ease that do the more civilised, and the tone and development of their muscular system ensures a more rapid and perfect involution. It is extremely likely that cycling is an advantage rather than a disadvantage in the particular respect under consideration as well as in others, and that excessive riding, either on account of atony caused by the pressure thereof or through muscular development induced by the exercise, helps rather than hinders.

Mr. McVitie applied short forceps to his cases "without tearing the perineum in the slightest." Does this argue in favour of his skill, or is it the plainest proof that there was nothing "unusually tough or unyielding"? Perhaps it indicates both, but most assuredly the latter. If the perineum in each of his cases had been so unusually tough and unyielding as to cause delay during the second stage, then it would almost certainly have given way under the strain of instrumental assistance. The class of case that exhibits an inordinately rigid perineum is that affected by age. A patient approaching forty years of age will generally suffer considerable delay, and her perineum will commonly tear under the use of forceps. There is toughness and rigidity, not on account of muscular atony or even through exercise and development, but on account of age pure and simple.

The advantages of cycling are so great—and none the less to women who contemplate marriage as well as those who may be living in their first years of married life—that it would seem to be undesirable that a pet diversion should have a stigma thrown upon its character unless the circumstances upon which it is founded are overwhelming and convincing. Cycling has saved many lives in both sexes, and no section has derived more benefit from the exercise than that consisting of the married and those about to marry. It would be monstrous if the idea were widely disseminated that such a class should strictly limit the amount because

Digitized by Google

certain primiparæ displayed symptoms that, after all, most practitioners have to deal with in all primiparæ.

Mr. McVitie's warning against "immoderate use of the wheel" is a good one for all ages and both sexes, but he should not proceed to abstract from the general bliss of a married existence one of the most enjoyable, popular, and healthful exercises ever made fashionable by throwing out such an awe-inspiring warning as he has without further reason than that given. Such a theory as he has presented might not only help to limit the amount of cycling in a particular section, but would most likely conduce to an unpopularity quite incommensurate and entirely undeserved.

I am, Sirs, yours faithfully,

Buckhurst-hill, July 5th, 1897. HAYDN BROWN.

"SOME NOTES ON THE LATE GRECO-TURKISH WAR."

To the Editors of THE LANCET.

SIRS,—In justice to my colleague Mr. Abbott, I should inform you that it was he who was in charge of the whole English expedition in the Greco-Turkish War, and had control of the larger Hospital at Chalkis. I would also add that Sir William MacCormac is the chief surgeon of the St. John Ambulance, whereas I am only chief surgeon of the Metropolitan Corps.

I have the honour to be, Sirs, yours obediently,

10, Maddox-street, Regent-street, W. SAMUEL OSBORN.

"THE VALUE OF AN EXCLUSIVE RED MEAT DIET IN CERTAIN CASES OF CHRONIC GOUT."

To the Editors of THE LANCET.

SIRS,—Mr. William Armstrong's paper under this heading in THE LANCET of July 3rd has shown the good that can be done by sometimes using what on the face of it appears to be a theoretically wrong diet. Reasoning as the writer does on the subject of auto-intoxication the diet has much in its favour; its results are good in his practice.

Speaking of children in whom the uric acid diathesis is sometimes very marked, I will give a case in my own practice which supports the assimilation theory. A child at two days old passed a quantity of red urine which alarmed the nurse, so much so that she saved me a specimen which on being tested was found to contain pure uric acid crystals. This urine was constantly being passed by the child, who screamed a great deal, had flatulence and sickness, and seemed very miserable altogether. The mother's milk was rich in cream, but turned acid rapidly. Careful dieting of the mother had no effect on the child for good. I found eventually that no milks would agree, so I abandoned milk and put the child on mutton juice. This agreed perfectly, the crying and sickness ceased, the general aspect of the child changed for the better, and the uric acid ceased to be marked after twenty-four hours of mutton-juice feeding. I gradually brought the feeding back to a sterilised cream mixture; the child is now well and taking food without difficulty. Curiously enough the family history of this infant reads like a list of Spa patients—viz., paternal grandmother has rheumatoid arthritis; the father has passed quantities of uric acid calculi; the mother has what Sir Willoughby Wade would call gouty neuritis accompanied by acid dyspepsia.

When Dr. Eustace Smith introduced meat-juice feeding he saw the wonderful way in which the albumin was assimilated, and I am quite convinced that it is in cases of uric acid diathesis that milk-mixed carbohydrate diets often disagree. Beef-tea I never give to children, as I only see harm from its use. In several other cases of children unable to digest milk well I have noted uric acid, but the family history is not so marked. When one considers that sugar, which is almost harmless in itself, can (as Sir Dyce Duckworth has pointed out) by setting up fermentation produce flatulence and acidity, it is obvious that carbo-hydrates may retard stomach digestion by acting as diluents alone, as well as by improperly fermenting and throwing the whole digestive tract out of gear by sending into the duodenum a fermenting mass, the toxins of which are absorbed—veritable taskmasters to an overworked system. Sir William Roberts has called attention to the value of mixed diets, and they certainly are more comfortable than the single red meat and water or vegetarian; but in the special cases mentioned by Mr. Armstrong the microbes must be mastered.

I am, Sirs, yours faithfully,

LENNOX WAINWRIGHT, M.D. Brux., &c.

Folkestone, July 19th, 1897.

CERTAIN POINTS IN THE CAUSATION AND TREATMENT OF SPINAL CURVATURE.

To the Editors of THE LANCET.

SIRS,—In a paper recently published on the above subject Mr. Barwell again draws attention to the condition which he terms "amesial pelvis," and he alludes to a figure of this condition in the last edition of his work on Spinal Curvature. In a work on the same subject now in the press I have discussed this condition, and I have shown that the "amesial pelvis" is not the whole story. Briefly the facts are these. Mr. Barwell has only taken his plumb-line from the "vertebra prominence," and noticed that the rima natium is to one or other side of it. If Mr. Barwell had taken the plumb-line from above the patient's head to the ground between her feet he would have found not only the pelvis but also the whole body amesial. The figure he alludes to in his book has the plumb-line passing through the middle line of the head to midway between the heels. This I believe to be a most unusual condition for a curvature patient. Mr. Barwell's account of how he arrived at this diagram explains the error. She was examined "piecemeal," "and the result embodied in an outline sketch." If in his second figure a vertical be drawn up from between the knees, it will not pass through the middle line of the head, but very much to one side of it. It would pass still more to one side if drawn up from between the heels. Therefore the head as well as the pelvis and all the intermediate portions are amesial. This condition I have found to be nearly if not quite universal in cases of lateral curvature. As to the reason of this amesiality, I believe it has its first cause in general muscular weakness. The body bends to one or other side because the muscles are not strong enough to hold it straight, much as a willow stick bends to one or other side when stood on end, whilst a brass rod of the same diameter would remain straight. The side to which the amesiality occurs, depends on any cause, such as an habitually bad position, which weakens the ligaments on one side of the spine by frequently over-stretching them. Once amesiality has commenced, curvature has begun. Amesial pelvis is, therefore, but a part of a general amesial condition. This amesiality causes an inequality in the amount of weight borne by each foot. If Mr. Barwell will examine the boots of his second case with amesiality to the right he will probably find that the outer side of the right sole and the inner side of the left show most signs of wear. I can quite corroborate Mr. Barwell's statement that the amesial pelvis "is generally also oblique." It must be so if the legs are of equal length. This is obvious from ordinal mechanical considerations.

Mr. Barwell has undoubtedly proved the uselessness of most spinal supports. The revulsion of opinion has, as usual, gone too much the other way, and I should like to say a good word for Fig. 3 in his paper. This is one of the modifications of the late Mr. Chance's instruments, and is notoriously very largely used by another eminent spine specialist. At the present time I am treating several patients with them, and though I am even more alive than Mr. Barwell to the amesial pelvis, I do not find it a bar to fitting the instrument and getting a great deal of good from it. The plates are not meant to act "with sufficient power and constancy to have an effect on the most prominent part of the curve," nor *when properly applied* can one "with the greatest ease sway the whole thing from side to side." What is claimed for these instruments, I can testify that they do: (1) they keep the spine in as upright a position as possible, for flexion increases the deformity and especially increases the rotation; (2) this is done by shoulder-straps, which only prevent the shoulder from falling forwards and do not otherwise limit their movements; (3) this constant keeping back of the shoulders tends to develop the flattened chest, removes stoop, and therefore cures part, whilst it removes an active cause, of the deformity; (4) they limit movement into a worse position when the patient is erect, and when at rest

Digitized by Google

they form a portable spinal chair on a principle I have described elsewhere; (5) they do not limit, but rather tend to produce, movement into a better position and are, therefore, actively curative. It is not my object to advocate their use for all cases of curvature, such as, I believe, has been done. In a certain minority of cases I have found them useful adjuncts to other treatments.

I am, Sirs, yours faithfully,

Folkestone, July 18th, 1897. PERCY G. LEWIS.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editors of THE LANCET.

SIRS,—You were good enough last year to substantially help the Factory Girls' Holiday Fund by publishing an appeal on its behalf, and we trust that you will again grant it a similar favour. As might have been expected in view of the heavy demands which have been made this year upon our sympathy and resources, the amount of support the fund has received is as yet quite insufficient for its work; but we earnestly appeal to the generous not to allow our year of rejoicing to bring disappointment to the hundreds of poor women and girls who are at this moment eagerly counting upon a week or fortnight's escape from the unchanging drudgery of their toiling lives. The conditions of modern industry make it a sad necessity that women must work as hard as men, and as a result our hospitals are full of overworked and underfed women and girls. On the principle that prevention is better than cure it is wished to give as many of them as possible the chance of breathing pure air, of having good food, and of enjoying the unwonted luxury of rest for at least one week of their weary year. Short as the holiday is it makes a wonderful change in the pale, dull-eyed workers, and all who help would feel well repaid to see the sunburnt, happy faces that come back to work. We know the physical benefit it is to them, and we know the happy memories of their short stay in the country does something to soften and purify their hard lives in London.

Subscriptions will be gladly received by the honorary secretary, Miss Canney, St. Peter's Rectory, Saffron-hill, London, E.C., or by the honorary treasurer, Miss M. Wyatt, 1, Routh-road, Wandsworth-common, S.W.

We are, Sirs, yours obediently,

HENRY SCOTT HOLLAND. ROBERT F. HORTON.
ELIZABETH GARRETT ANDERSON. FRANK LLOYD.
H. ADLER, Chief Rabbi.
M. C. TREVOR.
NORFOLK. EDWARD CANNEY, Chairman of the Executive Committee.

July 19th, 1897.

*** DR. BYROM BRAMWELL has written to us pointing out that one sentence in our leading article of July 10th on Aphasia and Disorders of Speech "might be likely to convey to the readers of your article the idea that my views as to the action of the right hemisphere were formed subsequently to, and based upon, Dr. Bastian's lectures." We have, therefore, pleasure in stating that the simultaneous publication in our columns of Dr. Byrom Bramwell's papers and Dr. Charlton Bastian's Lumleian Lectures was an accidental coincidence due to the fact that the great pressure on our space inevitably leads every now and then to delay in the insertion of contributions, more especially when they are of such a length that they can only appear in successive issues of THE LANCET. Dr. Byrom Bramwell's series of cases of aphasia was an instance of this kind, the manuscript having been in our hands for a considerable time (several months) before the first instalment appeared in our issue of March 20th last; it was completed in eight articles, the final one of which was contained in our issue of May 22nd.—ED. L.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD, LONDON.—The Goldsmiths' Company and the treasurer of the hospital, Mr. Hope Morley, have respectively sent £100 and 50 guineas to the Royal Chest Hospital, City-road, E.C.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Society of Chemical Industry.

THE annual general meeting of the Society of Chemical Industry was held on the 14th inst. at the Owens College, under the presidency of Dr. Edward Schunck, F.R.S., who gave a most interesting address. A large portion of it consisted of personal recollections of some of the most notable men connected with the history of chemical technology in the Manchester district, especially of Dr. Dalton and Dr. Charles Henry, who practised for some time as a physician in Manchester. He was a favourite pupil of Dalton, and after a time gave up the practice of medicine for that of chemical manufacture, in which his family had been successfully engaged for some generations. His grandfather was the first to prepare the so-called "Henry's magnesia," the distinctive merit of which consisted, according to Dr. Schunck, in its forming with water a soft, milk-like emulsion, without any grittiness, giving no deposit even on long standing. This property was said to be due to precipitation with potassium carbonate in place of sodium carbonate, and to using the solution of magnesia in a very concentrated state, "a proof, if correct, of how often success in manufacturing manipulation depends on minute details." Dr. Charles Henry wrote a life of Dalton, "a classic production, forming one of the most important volumes of the Cavendish Society's series," and to him Dalton bequeathed the whole of his scientific apparatus, which was afterwards given to the Manchester Literary and Philosophical Society, in whose rooms it is still to be seen.

Incidentally the colouring of pickles was referred to in connexion with the chemistry of chlorophyll. The opponents of what Dr. Schunck speaks of as the "so-called adulteration" producing "the much admired vivid green colour" say that it is produced by the addition of some salt or compound of copper. He says the point to be determined is whether the quantity of copper present is "as injurious as has been represented." The green colour is that of a derivative of chlorophyll—cupric phyllocyanate—which has a considerable tinctorial power. Most vegetables contain less than 1 per cent. of chlorophyll, which itself "yields by decomposition a not very large amount of phyllocyanin, and that the cupric phyllocyanate contains, according to my determination, only 9 per cent. of copper, and when we consider, moreover, that the copper is contained in the cupric phyllocyanate in a form in which it cannot be detected by ordinary reagents, then, I think, we may arrive at the conclusion that the small quantity of copper contained in a green pickle or vegetable cannot be very injurious." He goes on to say, however, that the mischief is "that the pickling vinegar, containing usually an excess of copper salt, is allowed to stand in contact with the pickles, and may be taken with them to some extent." The conclusion he comes to is that if this vinegar is poured off, the vegetable washed with water, and this also poured off before fresh vinegar is added, "then I feel convinced any quantity of the product may be eaten with impunity." Very consolatory to the devourers of pickles, but it would be better to have them without copper, even though in the form of cupric phyllocyanate.

Dr. Schunck also referred to the condition of the Ship Canal. He said that when Manchester was smaller and sanitary conditions not much thought of "it seemed only natural that our one river should carry away the sewage and waste water of the town to the sea," but now the effluent water is impounded in the Ship Canal, where it ferments and decomposes, giving off fœtid gases. With regard to purification, all that he thinks certain is that a successful scheme, even if possible, is sure also to be costly. Then follows some curious reasoning. Some of a sceptical turn may ask if there is evidence to satisfy a scientific inquirer that our polluted streams are as injurious to health as is sometimes asserted. Sentimental and æsthetic objections must not be brushed aside as of no importance, because what depresses the mind affects also the bodily health; "but the question is whether we are justified, except on the highest and most urgent grounds, in saddling the towns and manufacturers of Lancashire—in face of a declining trade—with the enormous outlay which, according to experts, would be necessary to effect the purification of our rivers to the satisfaction of the authorities." Dr. Schunck does not tell us

Digitized by Google

what death-rate, what amount of ill-health and depression—most costly as they are to a working population—he would require before cleansing our rivers. It is not encouraging to hear that he has no doubt as to the increased pollution of the air by coal smoke, and that it is much greater than it was years ago. Sometimes it is contended that this is due to the number of small tenements erected of late years, but he is certain that "the chief part of the smoke comes from factories and works," and it is satisfactory to find that he thinks it "is a disgrace to our manufacturers, a disgrace to our municipalities, a disgrace to the community generally." We may hope that his audience took this to heart, for chemical manufacturers are among the greatest polluters of the air of Manchester, and not long ago sought special privileges as to evolving smoke. Dr. Schunck, noting the much greater purity of the air after rain, suggests the possibility of producing artificial showers by means of a rose attached to the end of a water-hose to wash down the suspended carbon, the sulphurous acid, and other impurities, at the same time watering the streets. When this is carried out Manchester will more than ever deserve its reputation of being a rainy city.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Rabies and the Muzzling Order.

IT is with much regret that I have to record the occurrence of a serious accident to Dr. Allen, Professor of Physiology at Mason College, on Sunday last. It seems that a fox-terrier dog without a muzzle had been lurking about the district of Dr. Allen's residence for some days, and on Sunday found its way into the drive approaching the house. Dr. Allen offered some water to the dog, whose excitement was increased by being followed by a number of children. This the dog refused, and Dr. Allen, fearing for the safety of the crowd, put on a pair of kid gloves and seized the dog by the back of the neck, forcing it into the stable. During the struggle the dog bit Dr. Allen twice on the right hand and once on the left. The dog was afterwards killed by the police and its body examined by a veterinary surgeon, who pronounced that it had been the subject of rabies. A portion of the remains was packed up and sent to the Pasteur Institute at Paris, whither Dr. Allen proceeded at once for treatment himself. The many friends of Dr. Allen are hopeful that his injuries may not be serious and that the result of his journey to Paris may prove beneficial and permanent.

Epidemic of Brutality.

The periodic element of ruffianism which seems to be endemic in large towns has broken out recently in the midst of the city, as shown by violent attacks upon the police. Last Sunday night the disturbance resulted in the death of a fine young policeman, whose head was fractured by a brick thrown by one of the crowd. The patient, aged twenty-eight years, was conveyed at once to the General Hospital, where he succumbed in four hours, not regaining consciousness. These savage attacks upon the police in the execution of their duty demand prompt and even drastic measures from the authorities. Law-abiding people are not safe and dread certain localities of the town after daylight hours, when drunken and disorderly mobs of roughs make the neighbourhood dangerous. A salutary punishment of a number of the residuum of this class would do more to suppress these disturbances than the appeals to humanitarian sentiments which generally accompany the magisterial sentences.

Lavatories for Females.

The Public Works Committee have decided to erect two lavatories in the centre of the city for the convenience of females. The necessity for this action is obvious from a sanitary point of view, and if well managed and properly kept no doubt they will add to the comfort of a large number of people.

The New General Hospital.

On the invitation of the medical staff, the day after the opening of the hospital by Princess Christian a large number of the profession were entertained and shown over the new buildings. Some three or four hundred responded and evinced their approbation of the admirable arrangements made for the reception and treatment of patients. The adaptation of the various parts of the building for the purposes intended gave unqualified satisfaction. Much interest was shown in the chapel, which is fitted with beautiful marble, the gift of Mrs. J. C. Holder, and in the fittings of the children's wards, which have been mainly carried out by the girls of King Edward's High School. Considerable advance has been made towards the completion of the building, and it is hoped that it will be ready for patients by the end of September. The details are infinitely numerous, and require constant supervision which is ably supplied by the committee and house governor, Mr. Collins.

July 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Anderson's College Medical School, Glasgow.

THE governors of this school have decided not to re-appoint Dr. Campbell Black to the chair of Physiology. Dr. Black has occupied the chair during the last six years. From a correspondence printed in the *Glasgow Herald* it appears that some difference of opinion has arisen between Dr. Black and the governors in reference to certain addresses which Dr. Black delivered to his class, and which were reported in the public prints. A committee was appointed to meet Dr. Black, and though, according to his published statement, he "besought instruction in the matter" the issue is as stated above. The chair is now advertised as vacant.

Glasgow and the British Association.

At a meeting recently summoned by Lord Provost Richmond, and attended by representatives from the magistrates, the University, St. Mungo's College, the Philosophical and other scientific societies, it was unanimously decided to invite the British Association to meet in Glasgow in the autumn of 1901. The date selected is the year in which Glasgow is to have its second international exhibition. The first exhibition was in 1888, the year when the British Medical Association held its annual meeting in the city.

Medical Appointments, &c.

Mr. J. A. Anderson, M.D. Glasg., and Mr. Andrew Cluckie, M.B. Glasg., have been elected district medical officers by the Stranraer parish council. Mr. J. Duffus, M.D. Aberd., and Professor J. G. McKendrick have been admitted to the commission of the peace for the county of Kincardine.

Model Lodging-house, Aberdeen.

Rapid progress is being made with the construction of the corporation lodging-house, East North-street, Aberdeen, where 261 male lodgers will be accommodated. The scheme is being carried out under the Housing of the Working Classes Act. The total cost of the buildings will be £12,000, and the town council entered into contracts just in the nick of time, the prices for building work having greatly increased since then. There are in all five blocks, three of which will be four storeys in height. The front dressings are of fine white granite, and those in the back walls are of red granite. There is a large amount of masonry work in the contracts. The reading and recreation rooms, lavatory, and bath accommodation, and the lighting and ventilation will be excellent, so that the lot of the "dosser" who is able to pay the fee expected will be a great improvement on the previous state of affairs among the itinerant population in Aberdeen. The undertaking will be a source of considerable profit to the corporation. Messrs. Marshall and Dick, Newcastle-on-Tyne, are the architects of the buildings, and Mr. John Ogilvie is inspector of works for the corporation.

(FROM OUR OWN CORRESPONDENTS.)

The Dublin Sanitary Association.

AT the last meeting of the council of the Dublin Sanitary Association the President, Dr. J. W. Moore, Mr. Frank Newell, one of the honorary secretaries, and Mr. Jonathan

Digitized by Google

Pim, were selected to represent the association at the approaching twelfth annual meeting of the International Medical Congress at Moscow.

Pauper Nursing at the North Dublin Union.

The city coroner held an inquest on the 20th inst. on the death of a child, aged five months, who died in the institution, and who was found in a half-starved condition. During the inquiry it transpired that the child, who was an orphan, was left in the charge of unskilled and pauper nurses. The jury, after a long investigation, found a verdict of manslaughter. This will probably have the effect of directing public attention to the state of things which prevails in connexion with union nursing.

The Coombe Lying-in Hospital, Dublin.

At the recent annual meeting of the friends and supporters of this old-established institution the master (Dr. Kidd), in submitting the report, called attention to the fact that among the 418 patients treated in the internal midwifery department during the past twelve months the mortality was *nil*. In other words, no death occurred.

New Police Cells at Belfast.

At an inquiry held in Belfast on July 15th by the inspector of the Local Government Board the Belfast Corporation applied, among other things, for leave to borrow £11,000 on the proposed new police cells, which are so desirable, the present arrangements being in a very unsatisfactory state. There are to be 51 cells for the accommodation of 107 prisoners—namely, 19 single cells for males and 4 for females, and 18 large cells for males and 10 for females, each capable of containing three prisoners. There are to be new offices for the Commissioner of Police, the detective department, a medical man and matron, and all the most recent improvements will be embodied in the plans.

The Infectious Diseases Hospital, Belfast.

Dr. Clibborn, the medical inspector of the Local Government Board, held an inquiry on July 19th in Belfast as to the suitability of the proposed site at Purdysburn for the new infectious diseases hospital. The chairman of the Public Health Committee (Alderman Graham, M.D.) having given evidence in support of the situation, Dr. Clibborn said that he had received a printed memorial from a number of medical men of Belfast objecting to the site on various grounds, but, properly speaking, as they were not there he did not think he should go into that; but, to prevent any discussion afterwards, or any statement to the effect that the views of those objectors were not taken into account, he would ask Alderman Graham's opinion about certain statements in the memorial. The main objection was in reference to the distance from the centre of the city—four miles; but Alderman Graham gave statistics of other places in which the infection hospital was also at a distance from the towns. He also added that the Ulster Medical Society has unanimously come to a conclusion that they would offer no further objection to the site. The President of Queen's College had also written a letter opposing the site, and the medical inspector said that if he had been present he would have been very happy to have heard him. The Corporation ask a loan of £20,000, and Dr. Clibborn will report on the whole matter.

A Question of Fees for Expert Evidence.

Last week, at the Cork summer assizes, Dr. O'Connell, dispensary medical officer, Castlemartyr, appealed from a decision of the Recorder dismissing a claim of one guinea which he sought to recover from the Midleton Board of Guardians for attending a sanitary prosecution on behalf of the guardians. The defence was that the fee of one guinea was included in the salary of £25 paid to the plaintiff as sanitary medical officer of the union. After arguments on both sides his lordship, Mr. Justice Murphy, said that as the Medical Association appeared to be practically the plaintiffs in this action, and as the question was a serious one, he was prepared, if necessary, to state a case, but his present impression was that the law was with the defendants, and that the fee was included in the fixed salary of £25 as sanitary officer. He would let the case stand for some time to give the plaintiff an opportunity of considering whether he would have a case stated.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Serum Treatment of Plague.

AT the Academy of Medicine M. Roux read for the writers the long report of MM. Wyssokowitch and Jobobat upon the plague in Bombay. These gentlemen made exhaustive experiments in the laboratory which they set up immediately upon their arrival, and reported that the first cases were all bubonic in character, but that later the type changed and pneumonia became the prominent symptom. They found general hypertrophy of the lymphatic system to be common, and due rather to the swarming of the bacilli than to any hyperplasia of tissue. In the pneumonic cases, as would be expected, the bronchial glands were attacked. In the intestines they found punctiform hæmorrhages, while the mesenteric glands were engorged, but according to MM. Wyssokowitch and Jobobat these lesions were all secondary to the general "*septicémie pesteuse.*" The bacillus they considered to obtain entrance both by the integument and by the mucous membrane, so that while external buboes were formed a fatal pulmonary condition could be set up at the same time by the affection of the bronchial glands. In support of their hypothesis that the bacillus can traverse healthy skin they conducted some experiments upon macaque monkeys, which are very susceptible to plague, the slightest scratch made upon the palm of the hand of one of these monkeys with a needle dipped in plague culture causing bubonic plague to develop without it being possible to detect the original scratch. The result of their experiments was to convince them that the healthy skin could be traversed by the bacillus. The plague they found could be artificially produced in the pneumonic type by introducing the poison into the trachea under chloroform, but the mucous membrane of the œsophagus and stomach were more resistant, supporting their view that the punctiform hæmorrhages found post mortem were part of a general condition, and were not a spread of local mischief. With regard to the protective action of the serum MM. Wyssokowitch and Jobobat treated monkeys with variable quantities of Yersin's preparations, but the state of immunity when reached did not last for more than ten or fifteen days, and a like temporary result was arrived at when a method proposed by Haffkine, in which the culture to be injected was sterilised by heat, was employed. The immunity in each case appeared to commence immediately after the injection. The importance of these observations seemed to them to lie in the fact that it was possible to immunise the human subject for definite periods by repeated injections. With regard to the curative action of the serum, they experimented with ninety-six monkeys, which they inoculated and then injected at varying times and in varying doses. From their experiments they concluded that careful dosage, and especially early employment of the serum, were necessary for the success of the treatment. When the injection was made during the first two days of the attack the serum seemed to have its full curative power. Later in the disease it lost its efficacy, although improvement had been observed up to the sixteenth or eighteenth day. On the whole, they considered that mortality from plague might be diminished by one-half by employment of the serum, although the pneumonic form was not affected by the injection but remained uniformly fatal.

X Rays and Tuberculosis.

M. Bergonié, of Bordeaux, has recently made some researches into the action of the x rays upon the progress of pulmonary tuberculosis. The patients were laid out on beds, and the surface of the skin being covered with a light covering the Crookes's tube was placed over the affected region at a distance of twenty centimetres. The exposures lasted for ten minutes and resulted in no erythema or injury to the skin. In five of the patients only was the treatment persevered with. In two of these, where acute phthisis chanced to be aggravated by the results of alcoholism and poor living, there was no improvement whatever either in the general or the local conditions. Three chronic cases of pulmonary tuberculosis showed some amelioration of general condition, but no alteration at the seat of mischief and no arrest of the disease. In three other cases the rays

Digitized by Google

had no appreciable action. The bacillus of Koch seems not to have been modified in its behaviour, an observation which was supported recently at the Biological Society by M. Blaise, who read a note affirming that the x rays had absolutely no action whatever upon microbic cultures.

France and Foreign Medical Students.

At the Municipal Council a resolution has just been adopted that the Government should be asked to annul the by-law of two years' standing under which foreign students desiring to study medicine in France were sent to the provincial universities. Previously to this by-law the foreign student was in a better position than the French student because he was not compelled to serve three years in the army or to pass a matriculation examination of equal severity. As a set off to this great advantage foreign students were therefore drafted to the provincial centres instead of being permitted to work at the *Faculté de Paris*. But more recently a rule has come into force whereby the degree of Doctor of Medicine shall only give the right of practice in France or French possessions to such students as shall have passed the usual French preliminary examinations and have served three years in the army. Native talent is considered by the Municipal Council to be sufficiently protected now, and the Prefect of the Seine has promised to communicate this view to the Government. The commencement of the next November session will therefore probably see foreign students again inscribing their names at the *Faculté de Paris*, but the degree which they expect will not give them the right to practise in France unless they conform to the new regulations.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Poisoning by the Fumes of Nitric Acid.

ON May 17th a serious fire, caused by the bursting of a carboy filled with nitric acid, broke out on the premises of the well-known chemical factory of Bayer and Co. in Elberfeld. The conflagration very soon involved the whole building where the stock of this chemical was kept, and a high wind drove the smoke and fumes towards the firemen, who were immediately seized with violent cough, dyspnœa, nausea, and headache, rendering it necessary for them to be relieved every few minutes. Strange to say, the men who were thus attacked soon felt quite well again, so that they were able to continue on duty and to walk home when the fire was over, but after several hours thirteen of them developed symptoms of poisoning, the consequence being that eleven were taken to the hospital, whilst two died before they could be admitted. Dr. Künne, chief physician to the hospital, has described the cases in the last number of the *Deutsche Medicinische Wochenschrift*. The symptoms differed much in their intensity, but all the patients suffered from dyspnœa, vomiting, cyanosis of the skin, sopor, and clonic convulsions. The heart's action was at first accelerated, but within a few hours became very slow, making only from forty-five to fifty-four beats per minute; sometimes the pulse was irregular. All the patients, even those who did not cough very much, complained of oppression in the chest and great pain near the sternum. This was followed by severe bronchitis, the expectoration being sometimes of a yellow colour and sometimes tinged with blood. Some of the patients had a difficulty in swallowing, due to inflammation of the fauces. Of course they were unable to sleep, but only a few became feverish. Albumin was found in the urine of three of them for periods varying from three to eight days. Seven of the men recovered completely within ten days, but the remaining four were very weak and off duty for about a fortnight longer. It appears from these cases that nitric acid has a very injurious influence on the human body, and that the opinions to the contrary effect formerly held by some medical men were erroneous; the nature of the chemical substance which is formed when it is introduced into the blood is not yet known, but it obviously affects the vaso-motor and respiratory organs, the kidneys, and the nervous system. Medical treatment is restricted to the alleviation of symptoms. Fires in chemical works are often extremely dangerous to firemen. An occurrence similar to that at the Elberfeld factory happened recently in Schering's chemical works in Berlin, when no less than three officers and sixty men of the fire brigade showed symptoms of poisoning, and were rendered unfit for duty; their cases, however, have not yet been described in the medical journals.

Vaccination and Tuberculosis.

The Government having asked for information as to whether vaccination makes the individual more liable to tuberculosis, the scientific committee of the Royal Medical department (Wissenschaftliche Deputation für das Medicinalwesen) has given the following opinion. Tuberculosis being the most frequent of all existing diseases a considerable number of vaccinated or re-vaccinated persons must inevitably suffer from it sooner or later, but there is no reason for supposing that such persons have an exceptional liability to tuberculosis. If the spread of tuberculosis were caused by vaccination the mortality from it would have increased since the introduction of compulsory vaccination, but the fact is that the army returns prove that tuberculosis has become less frequent since the enactment of the vaccination laws. Diseases produced by a faulty method of vaccination, such as erysipelas, septic infection, &c., may impair the health and render the tissues less able to resist the entrance of the tubercle bacilli; the dissemination of tubercle bacilli previously present in the glands of children may also be facilitated by feverish complications of this kind, but apart from these exceptional cases the opinion that vaccination may be the cause of tuberculosis is erroneous.

July 19th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Missing Surgeon of the Bottego Expedition.

IN THE LANCET of May 15th. p. 1379, I gave some account of the destruction of Captain Bottego and his expedition, indicating at the same time that the fate of Dr. Maurizio Sacchi, who acted as surgeon to the force, was as yet uncertain. Information just received by the Sacchi family appears, happily, to put his safety beyond a doubt. The moment the disaster that befel the expedition was known they addressed a communication to the Abyssinian Ras Maconnen, begging him to afford them what details he could gather as to the fate of Dr. Sacchi. To that communication they have now had a reply from the Ras himself, written in French, and dated Harrar, June 28th. "Doctor Maurizio Sacchi," he says, "is alive, and in the day now passing is at Shoa." Then follows the comforting assurance: "You may be quite at your ease on his account. No harm will overtake him. When he passes through Harrar I promise you that I shall protect him and assist him to the best of my ability." The joy of the Sacchi family may be imagined, and all Mantua, city and province, the natal district of Dr. Sacchi, is naturally jubilant. It has further been announced that the survivors of the Bottego expedition, Lieutenant Vannutelli and Sub-Lieutenant Citerni, are at present at Adis Abeba, in good health and under the roof of the Italian envoy, Major Nerazzini. According to these gentlemen Dr. Maurizio Sacchi happened not to be with the expeditionary force on the fatal day, having had occasion to detach himself from the main body on its reaching the elevation of Lake Rodolfo. Meanwhile, Itallans are commenting with admiration on the courtesy and neighbourly kindness of Ras Maconnen—qualities displayed towards them not for the first time, and, indeed, quite in keeping with all their more intimate experience of King Menelik and his allies.

Anthropometry of the Italian Army.

The colossal armies of the great Continental powers present facilities, otherwise unattainable, for more than one department of anthropological inquiry. Italy, if she has not led the way in utilising those facilities—Germany, I believe, having the priority—has followed suit in a commendable manner. As far back as 1879, at the instance of Lieutenant-Colonel Guida, M.D., the War Office gave instructions that for every soldier on his joining a regiment there should be kept a "foglio sanitario" (sanitary sheet), noting his general physique (colour of hair, eyes, and skin; development of forehead, nose, mouth, and chin; eyesight; the maximum antero-posterior and transverse diameter of the cranium;

Digitized by Google

stature; thoracic perimetry; and weight); while progressively, throughout his period of service, recording the limits of stature, thoracic perimetry, and weight, repeated year by year; and, finally, registering all the sanitary vicissitudes of which he was the subject. Between 1879 and 1883 the "fogli sanitari" were 300,000 in number, and the War Office charged Captain Livi, M.D., with digesting and analysing the material thus collected. A most instructive and interesting work is the outcome, the title of which I transcribe from the copy now before me for the benefit of those of your readers engaged in anthropological study: "Livi, R——, Antropometria Militare, Parte I., Dati Antropologici ed Etnologici. Con Atlante. Roma." Another publication, now in the press, will take note of the pathological, hygienic, and demographic conclusions to be drawn from the "fogli sanitari," with their suggestions for modifying regulations hitherto in force, for improved methods of recruiting, and thereby for diminishing the "morbosità" (tendency to disease) and "mortalità" of the soldier.

July 18th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The International Medical Congress in Moscow: The Reception by the Czar.

IT has been known for some time that His Majesty the Czar, as patron of the Congress, has consented to receive deputations from all the foreign countries represented at the Congress. The arrangements for the reception have now been made public. It will take place before, not after, the Congress, on Aug. 5th (17th); that is to say, two days before the opening of the proceedings in Moscow. There will be only one representative from each country, his selection being left to the national committee of the particular country. Professor Sklifosovski, the president of the organising committee, will have the honour of making the presentations to the Emperor. It is not stated where the reception will be held, but it will certainly be either in St. Petersburg itself or in the summer palace at Peterhof, where the Czar is at present residing.

The Moscow Municipality and the Congress.

The Executive Committee of the International Congress recently approached the *Duma*, or Town Council, of Moscow, suggesting that it was desirable that the municipal authorities should entertain the members of the Congress at some form of reception or rout. The council has, however, by a small majority rejected the proposal, although it was supported by the "finance" and "social" committees of the council. Instead of entertaining the members the council proposes to commemorate the Congress by instituting an international prize, to be given every three years, for the best work upon Public Health or Epidemiology. The sum set aside for this purpose is 16,450 roubles, or about £1800, and the value of the triennial prize is fixed at 5000 francs, or £200.

Other Arrangements in Moscow.

There will be three general meetings of the Congress, and these are fixed for Thursday, Aug. 7th (19th), Sunday, the 10th (22nd), and Thursday, the 14th (26th) of that month. The Grand Theatre in Moscow was originally proposed as the most suitable place for the general meetings, but it seems that it will only seat some two thousand people; so the first, which is expected to be the largest gathering, will take place in the Nobility Club (*Blagorodnoé Sobranjé*); the other two will be held in the Theatre. The Preliminary Programme of the Congress has just been published, and from this it will be gathered that there will be no lack of material for discussion either at the general or the sectional meetings. Already over 970 communications are promised, and it is rather curious to note that the three sections in which the largest number of papers will be read (if the present proportion be adhered to) are those of Hygiene, Surgery, and Nervous and Mental Diseases, in each of which over 100 papers are at present promised. Those with the smallest numbers are in the sections of Anatomy and Physiology.

Additional Orations at the General Meetings.

A list of the principal orators and the subjects of their communications was published in THE LANCET of May 29th. This can now be supplemented by the following. Professor Virchow's paper will be entitled, "On the *Rôle* of the Vessels in Inflammation"; Professor Lukianof's will be "On Inanition of Cell Nuclei"; Professor Metchnikof will discuss "The Plague"; Professor Robert (of Barcelona) will read a paper on "The Characteristics of Human Pathology in Relation to Therapeutics," and Professor Lannelongue (of Paris) one on "The General Treatment of Surgical Tuberculosis." Professor Danilevski (of Kharkof) will not read one of the orations as originally announced.

Official Representatives at the Congress.

It is said that official invitations to attend the Congress have been sent to the Bavarian Prince Ludwig Ferdinand and the Bavarian Duke Carl Theodore, both of whom are Doctors of Medicine. The names of a large number of official representatives at the Congress of Universities and medical and governmental institutions of all sorts are now published, and of these the following may be mentioned:—Edinburgh University will be represented by Professor T. R. Fraser; Glasgow University by Professors McCall Anderson, Ferguson, Macewen, Cameron, and Yellowlees; Cambridge University by Professor Clifford Allbutt; Dublin University by Professors Finny and Purser. France will be unusually well represented at the Congress. The Paris Medical Faculty alone is sending fourteen representatives, including such well-known names as those of Professors Potain, Lannelongue, Tillaux, and Le Dentu. The French army and navy will be represented by four medical men, one of whom will be Professor Dujardin-Beaumetz. It may be added that an unusual number of lady practitioners have become members of the Congress.

Reception and Accommodation of Members.

It is stated that twenty-three members of the Congress will be treated as guests of the Russian Court and provided with accommodation in one of the official residences of the Kremlin. The immense *Manége* in Moscow is to be put at the disposal of the Congress, and in this room will be found for many of the special offices in connexion with it. Each section of the Congress will have a separate office here under the same roof. Buffets will be provided, at one of which light refreshments in the form of "butterbrods" and beer will be obtainable without charge by members of the Congress. The reception of members on the first day will take place in the upper *Torgovie Riadui*—that is to say, in the large new arcade close to the Kremlin. The entertainment given by the medical profession of Moscow to members of the Congress will take the form of a concert, at which the excellent orchestra of the Philharmonic Society will perform. As in Russia the theatres are always closed during the summer months, and the actors and actresses (who are here, as of old in England, servants of the State) dispersed, it has been found impossible to arrange for a gala spectacle in the Grand Theatre, as had at first been hoped.

A Practical Hint.

A few words as to the weather which may be expected in Moscow in the month of August may be welcome to some Englishmen who are intending to come to Russia now for the first time. On the whole the climate of Moscow at that time is not at all unlike that of England at the same period. In both there is a certain element of uncertainty which it is well to be provided for. It is just possible that the week in August during which the Congress is to be held will be very hot, but so late in the summer the heat is scarcely likely to be intolerable. It is far more probable that the weather at that time will be but moderately warm; and the nights, it is more than probable, will be distinctly chilly. No member who brings a warm change of clothing in his portmanteau and a good warm travelling rug will be likely to regret it.

A Proposed International Jenner Society.

Dr. Hubert, Secretary of the Russian National Health Society, and author of the work on Jenner and Vaccination, more than once mentioned in the columns of THE LANCET, intends to propose at the Congress in Moscow a scheme for the formation of an International Jenner Society, for which he suggests the title "Jennerianum." There would, under the scheme, be a division of the society in each country, and the object of it would be to collect observations and statistics upon small-pox and vaccination. This would appear to be an appropriate time for starting a movement of the kind, and the proposed society would be a worthy commemoration of the centenary of Jenner's great work, more particularly if it led to a still wider spread of the practice of vaccination. The details of the scheme will be looked forward to with interest.

St. Petersburg, July 3rd (15th), 1897.

Obituary.

SIR JOHN CHARLES BUCKNILL, M.D. LOND., F.R.C.P., F.R.S., J.P., &c.,

FELLOW OF UNIVERSITY COLLEGE, LONDON; LATE LORD CHANCELLOR'S MEDICAL VISITOR OF LUNATICS.

ON July 20th Sir John Charles Bucknill died, after a long illness, at Bournemouth, aged seventy-nine years. He was born in the year 1817 at Market Bosworth, in Leicestershire, in which town his father, Mr. John Bucknill, was practising as a surgeon. At an early age he was sent to Rugby School, where Dr. Arnold had recently been appointed headmaster. Bucknill did not, however, remain at Rugby very long, but after a year or two was removed to the Grammar School of his native town, Market Bosworth, where he became a day scholar, living at home with his family. About 1835 he proceeded to University College, London, then possessed of the most notable teaching staff—certainly in London, and probably in the world: Samuel Cooper, author of the great dictionary, Robert Liston, and Richard Quain being the surgeons, Jones Quain the anatomical teacher, Robert Carslake the pathologist, John Elliotson and Anthony Todd Thomson being likewise members of the staff. Among his contemporaries at University College Hospital were the late Sir John Eric Erichsen and Sir Richard Quain.

In 1840 Bucknill took the degree of Bachelor of Medicine at London University, being placed first in the honours division in surgery and third in medicine. From the time of his graduation his association with the University was continuous. He became Doctor of Medicine in 1852, and shortly afterwards a Fellow of University College, and was for some years a member of the council of that body. Having qualified he became house surgeon to University College Hospital under Liston, who died shortly afterwards. In 1842 Bucknill married. His wife, who died in 1889, was the only child of Mr. Thomas Townsend, of Hillmorton.

In 1844 what may be truly termed his life's work began. He was appointed first medical superintendent of the new Devon County Asylum, which appointment he held for the eighteen most active years of his life. His work here was marked by a zeal and enlightenment which was a rare feature in asylum management in those days—days when the madman's usual lot taxed even the pen of Charles Reade to describe. His energy and success attracted the attention and earned the friendship of Dr. Daniel Hack Tuke, and it was at this time that the literary partnership which afterwards bore fruit of almost incalculable value to the profession was initiated. While at the Devon County Asylum Bucknill conceived the idea of a periodical journal to be devoted to asylum management. This project saw the light in the form of the *Journal of Mental Science* in 1853 under his editorship. This journal he personally continued to conduct until his retirement from Devonshire nine years later. His next journalistic venture was in 1855, when he founded the short-lived *Asylum Journal*. In 1857 he secured the Sugden Prize for a thesis on "Unsoundness of Mind in its Relation to Criminal Actions," a masterly exposition of the nature and limits of the criminal responsibility of the mentally afflicted, the result of long study and careful observation by one who possessed exceptional opportunities of arriving at the pith and essence of his subject.

Dr. Bucknill's time was not, however, entirely occupied by his asylum work and literary projects. His ever active and alert nature found fresh scope for the exertion of his energies in the direction of the National Defence movement. To him the great Volunteer movement of 1852 in no small degree owed its origin. Early in the year a meeting was convened at Exeter, presided over by Lord Fortescue, to consider the necessity for the enrolment of a corps of citizen soldiers, especially with relation to coast defence. It was pointed out that the last successful invasion of England—namely, that by William of Orange—was achieved by the landing of an army on the South Devon coast. Dr. Bucknill was the active spirit in this agitation, and in the end a resolution was unanimously passed in favour of memorialising the War Office asking for permission to raise a force to be known as the Exeter and South Devon Volunteers. The required powers having been obtained, Dr. John Charles Bucknill was enrolled as the first recruit in the first regiment of Volunteers established on the new system in the United Kingdom. The new corps was officially named the 1st Exeter and Devonshire Rifle Volunteers. From this time forward he was an enthusiastic volunteer and took a very prominent part in the duties, both official and social, of the corps, gaining thereby wide popularity in the county, and earning the respect and friendship of his comrades.

In 1859 he became a Fellow of the Royal College of Physicians of London, and held in that body the posts of Censor from 1879 to 1881 and of Lumleian Lecturer in 1877. In the latter year he also delivered the presidential address in the Physiological Section at the annual meeting of the British Medical Association in Manchester. Being appointed in 1862 by the Lord Chancellor to be Medical Visitor of Lunatics, Dr. Bucknill resigned his appointment at the Devon County Asylum and also the editorship of the *Journal of Mental Science*. He held his new position for fourteen years and during his tenure of the office did a great deal towards abolishing several then surviving anomalies in the management and inspection of lunatic asylums. He likewise succeeded in getting his sphere of jurisdiction into a thoroughly workable state, to the great advantage of his successors. As a public servant he showed himself a thorough man of business with a rare grasp of detail; it is, in fact, as an indefatigable and fearless official that he will long be remembered with feelings of gratitude. In 1876 he retired from this position and devoted himself to private practice, retaining, however, the deepest interest in the affairs of asylum management and the relations between crime and mental disease. Two years later—namely, in 1878—he was instrumental in founding the journal *Brain* and became its editor, which position he occupied for many years. His work in the columns of this magazine was one of the most successful of its features and showed no mean literary power apart from the sound knowledge which was only to be expected from so profound a psychologist.

The literary works of Sir John Bucknill are not voluminous, but all that he wrote was worthy of his high reputation as a physician and scholar. His love of, and close acquaintance with, the works of Shakespeare was throughout his distinguished career a notable factor in his personal life, and his two books, "The Pyschology of Shakspeare," published in 1859, and the dissertation printed in the following year on "Shakspeare and the Medical Knowledge of his Time," were valuable contributions to the literature of English poetry—the former disquisition, in particular, demonstrating in an exceptional degree the sympathetic insight which characterised all his literary work. His style as exhibited in this essay was marked by a rare ease of language and a thoroughness of erudition. His greatest work, "A Manual of Psychological Medicine," written in collaboration with his friend, Dr. Daniel Hack Tuke, contains, perhaps, the largest amount of useful information concerning insanity and allied neuroses of any work of similar scope in the language, the portions relating to criminal responsibility or irresponsibility being justly regarded, by jurists as well as medical witnesses, as authoritative. The arrangement of this work was somewhat new in the days when it appeared, it being based mainly on a statistical and tabular plan. "Care of the Insane and the Legal Control of the Mentally Deficient" appeared in 1880, and has been of the greatest value in the clear definition of the state of English law as regards the custody and restraint of the unsound in mind. "Habitual drunkenness" in its relation to crime was during this period (1878-1880) exercising the minds of the heads of the medical and legal professions to a great degree. The famous "Alcohol Controversy" had been carried on for some time in the pages of various reviews and journals. Among those who took a prominent part were Sir James Paget and the late Sir Benjamin Ward Richardson, but the medico-legal side of the question was almost entirely in the hands of Dr. Bucknill and Dr. Daniel Hack Tuke. The former contributed a very valuable essay on the Psychology of the Habitual Drunkard, which appeared in 1878 and caused at the time a considerable amount of controversy. Besides these, his more permanent works, Sir John Bucknill was the author of a large number of papers in the medical journals and was a frequent correspondent to the numerous learned societies of which he was a member. His last work, published in 1884, was "The Relation of Madness to Crime," a work of much practical value as well as interest, and may be fairly taken

Digitized by Google

as an example of the fruits of his long practical experience. Although a specialist he was in no way narrow. His own words, addressed to the Physiological Section of the British Medical Association at Manchester in 1877, although not intended to refer in any way to his own career, exemplify in a particularly apt manner his position. "This occasion seems opportune for speaking on a subject of great and general importance to us as specialists—viz., whether the customary practice of our speciality does not frequently tend to impair our usefulness by impairing our field of observation and narrowing our views of men and of society. ..... There can be no doubt that all special employment tends to narrowness of mind and that the learned professions suffer from this most notably. This was, indeed, long ago pointed out by Archbishop Whately in his work on 'Rhetoric,' and there can be no doubt there is a legist's narrowness, a priest's narrowness, and a physician's narrowness." He went on to insist on "the great need of the mental physician to breathe much of the pure air of rational life for the sake of both himself and his patients." "If there be one man more than another," he finally added, "who ought to be a man of the world it is the physician who has the care of the insane, for if he allows himself to become ignorant of the outside world he will make no comparison of the sane with the insane, and therefore will be liable to consider opinions and conduct morbid which are only strange." Sir John Bucknill carried out the precept here laid down. His social virtues will long be remembered by all who had the privilege of his acquaintance. He was throughout his career a man of the widest interests, and in the very liberality of his mental gifts did much more for his profession, and, above all, for the insane, than can well be estimated while his loss is fresh upon us.

Sir John Bucknill received the honour of knighthood in 1894 in recognition, not only of his wide learning and services to science, but in no small measure as an acknowledgment of his work in relation to the Auxiliary Forces. He was a justice of the peace for the county of Warwick and a Fellow of the Royal Society and a large number of other learned bodies both in England and on the Continent.

The funeral took place on Thursday at Clifton-on-Dunsmore, near Rugby.

JABEZ SPENCE RAMSKILL, M.D., M.R.C.P. LOND., M.R.C.S. ENG.

A NOTABLE figure in connexion with the early days of the National Hospital for the Paralysed and Epileptic has passed away in the person of Dr. J. S. Ramskill, who died on June 22nd at the age of seventy-three years. He received his medical education at Guy's Hospital, graduating as M.B. at the University of London in 1847 and proceeding to the degree of M.D. in 1849, and his first hospital appointment was that of physician to the Metropolitan Free Hospital. In 1859 he was elected assistant physician to the London Hospital and lecturer on medicine to the same institution, where his lectures on nervous diseases were much appreciated by the students and hospital resident medical officers. In 1859, too, he and Dr. Brown-Séquard were appointed the first two physicians to the National Hospital for the Paralysed and Epileptic in Queen's-square, a hospital at which he finally attained the position of senior physician, a post he held for many years. He was alway greatly interested in nervous diseases, and contributed the articles on Vertigo, Chronic Hydrocephalus, and Meningitis to "Reynolds's System of Medicine," as well as Lectures on Epilepsy to the *Medical Times and Gazette*. Dr. Ramskill was specially interested in the therapeutics of epilepsy, and it is to be regretted that he did not publish the results of a long inquiry he made as to the treatment of cases of epilepsy. He was a very genial and kind-hearted man, and will be greatly missed both by his numerous medical colleagues and his many friends outside the profession. He leaves a widow (his second wife) and one son.

MAX JOSEPH OERTEL.

BY the death, on July 13th, of Professor Max Joseph Oertel, medical science has lost one of its most eminent exponents. Born at Dillingen, Bavaria, in 1835, he studied philology and history at Munich before turning his attention to science and medicine. In 1860 he was appointed assistant to Professor Pfeuffer and a few years later pursued the study of laryngology under Professor Czermak, being himself appointed to the newly founded chair of Laryngology at Munich University in 1867. One of his earliest essays (1862) was upon the Endolaryngeal Removal of Laryngeal Polypus, which he was the first after Bruns to perform. The subject with which his name is mostly connected is that of the treatment of circulatory disorders, his contribution upon this being notable for the originality and breadth of view that it evinced. His essay appeared in 1882 in the "Handbook of Therapeutics," edited by Professor von Ziemssen, and his advocacy of graduated exercise and hill-climbing as a rational means of treatment of cardiac failure became known as the "Oertel cure." To the same work he contributed a lengthy article upon the Therapeutics of Respiratory Diseases. He had previously written upon Diphtheria in von Ziemssen's "Cyclopædia of Medicine," and his monograph, "Die Pathogenese der Epidemischen Diphtherie" (1887), completed a study commenced more than twenty years previously, when diphtheria was epidemic in Munich. That monograph, of which a full abstract was given in our columns at the time of its publication, was in the main a most profound analysis of the minuter histological lesions induced by diphtheria in the organs of the body, the text being accompanied by an atlas of beautifully executed microscopical drawings. Professor Oertel had, indeed, claimed the discovery of the bacillus diphtheriæ, but there is some doubt whether the organism he described is to be considered identical with that associated with the names of Klebs and Loeffler. At any rate, his demonstration of the cell lesions harmonised fully with the bacillary doctrine of the nature of diphtheria.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The following deaths have been announced:—Professor Johann R. von Lerch, at Hainfeld, on the 7th inst., aged eighty-three years. He had been dean of the medical faculty in the University of Vienna and also of the Doctoren-Collegium. Since 1888 he had lived in complete retirement.—Professor Oscar Boer, of Berlin, aged fifty years. He was a favourite pupil of Koch, and carried on many researches with him and with Behring, Ehrlich, Brieger, and Wassermann, mainly on the subject of immunity from infectious disease and the preparation and employment of antitoxic serums.

Medical News.

UNIVERSITY OF GLASGOW.—The following have passed the Final Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

Kilgour Adamson, John Allan, James Andrew, James Mitchell Bonar, John Ritchie Brown, John Ritchie Burns, Charles Cairnie, M.A. James Souter Christie, Walter Colquhoun, M.A.; John Crawford, James Donaldson, William Duncan, Charles Elphinstone Fleming, George Willmore Francis, James Graham, James Hogg, James Donald Holmes, Robert Kirk, George Louis Le Fevre, Archibald Livingston, William Martin, M.A., B.Sc.; Samuel Martyn, George Bain Murdoch, Andrew Brown Murray, Neil McCullum, John Allan Craigie Macewen, B.Sc.; John M'Laws, Murdo Norman Macleod, Norman Macnair, B.Sc.; Robert Nelson, William Park, Henry Joseph Rankin, James Rankin, B.Sc.; James Rutherfurd Ratcliffe, Neil Robson, William Kerr Russell, David Shedden Service, Harry Muir Watson, James Wells, and Robert Wilson. *Women.*—Agnes Jane Anderson, Annie Kirkby Anderson, Ursula Chaplin, Mary Philip Graham, Norah Kemp, and Merbai Ardesir Vakil, B.A.

For the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

Alexander Smith Allan, James Alston, William Cochran Burns, David Louis Cairns, Francis James Charteris, Joseph Adam Clarke, George Coats, George William Coats, James Duncan Cochran, Joseph Muir Corbett, Walter Scobie Findlay, M.A.; James Finlayson Fleming, Adrian Andrew Forrester, Thomas Bonnar Garvie, Lawrence Whitaker Harrison, Thomas Hunter, M.A., B.Sc.; Alexander Lawrie, William Mitchell Lindsay, William Glen Liston, John Watson Little, John MacDonald, James M'Haffie, David M'Kail, James M'Queen, M.A.; James Service Ormond, John Reid (Glasgow), Norman Emil Henry Scott, Robert Scott, Alexander Bankier Sloan, Samuel Macfarlane Sloan, David Steele Smith, John M'Callum Stewart, James Strang, Daniel Rees Thomas, Walter Lewis Thomson, William James Alexander Walker, William Watson, Ernest Watt, Edward Roberts Weir, John Wotherspoon, and David John Young. *Women.*—Jessie Hawkesworth Smith.

FOREIGN UNIVERSITY INTELLIGENCE.—*Kiel:* The title of Professor has been conferred upon Dr. L. Glaevecke, *privat-docent* of Gynæcology, and upon Dr. E. Paulsen, *privat-docent* of Laryngology.—*Manilla (Medical School):* Dr. Trinidad Pardo de Tavera has been appointed Professor of Anatomy; Dr. Ramon Fina y Baulenas, Professor of Surgical Pathology; Dr. Wenceslao Martinez, Professor of Forensic Medicine and Toxicology, and Dr. Mariano Garcia de Rey, Professor of Therapeutics.—*Naples:* The following have been recognised as *privat-docenten*: Dr. S. del Vecchio (Operative Medicine), Dr. Giovanni Miranda (Midwifery and Gynæcology), Dr. Carlo Gioffredi (Materia Medica and Pharmacology), and Dr. Giuseppe Ajello (Medical Chemistry).—*Vienna:* Dr. Richard Kretz has been recognised as *privat-docent* of Pathological Anatomy.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—PRIZE LIST.—*Winter Session, 1896-97.* Descriptive Anatomy—Junior: J. F. Peart, first prize (£3) and medal; W. R. Meredith, second prize (£1) and certificate. Senior: J. S. P. Stewart and Miss F. A. Dreaper (equal), first prize (£3) and medal; J. S. P. Stewart and Miss F. A. Dreaper (equal), second prize (£1) and certificate. Practical Anatomy.—First year: A. S. Ellenbogen, first prize (£3) and medal; J. F. Peart, second prize (£1) and certificate. Second year: J. S. P. Stewart, first prize (£3) and medal; Miss F. A. Dreaper, second prize (£1) and certificate. Third year: G. W. Little, first prize (£3) and medal; J. M. M. Crawford, second prize (£1) and certificate. Practice of Medicine.—D. A. Fitzgerald, first prize (£3) and medal; S. R. Godkin, second prize (£1) and certificate. Surgery.—A. S. Green, first prize (£3) and medal; F. J. Palmer, second prize (£1) and certificate. Midwifery.—F. J. Palmer, first prize (£3) and medal; D. Hadden, second prize (£1) and certificate. Physiology.—J. S. P. Stewart, first prize (£3) and medal; Mrs. H. L. Hennessy, second prize (£1) and certificate. Chemistry.—J. P. Byrne, first prize (£3) and medal; J. P. O'Donnell, second prize (£1) and certificate Pathology.—W. H. May, first prize (£3) and medal; P. H. Falkner, second prize (£1) and certificate. Physics.—E. Glenny, first prize (£3) and medal; S. Gordon, second prize (£1) and certificate. *Summer Session, 1897.*—Carmichael Scholarship: D. A. Fitzgerald, £15. Mayne Scholarship: F. J. Palmer, £15. Gold and Silver Medals in Surgery.—A. S. Green, gold medal; D. Hadden, silver medal. Practical Histology: H. Graff and Mrs. H. L. Hennessy (equal), first prize (£3) and medal. Practical Chemistry: G. Lewis, first prize (£3) and medal; R. H. G. Oulton, second prize (£1) and certificate. Public Health and Forensic Medicine: J. F. Meyler, first prize (£3) and medal; S. R. Godkin, second prize (£1) and certificate. Materia Medica: C. C. Meeke, first prize (£3) and medal; D. Jones, second prize (£1) and certificate. Practical Pharmacy: E. Glenny, first prize (£3) and medal; M. J. Johnston, second prize (£1) and certificate. Biology: J. Byrne, first prize (£3) and medal; E. Glenny, second prize (£1) and certificate. The preliminary examinations for the conjoint diplomas of the Royal College of Physicians and the Royal College of Surgeons will be held on Tuesday and Wednesday, Sept. 28th and 29th. The prospectus of the course of study can be had on written application to the Registrar, Royal College of Surgeons in Ireland, Dublin.

LONDON HOSPITAL MEDICAL COLLEGE.—The following is a list of the scholarships and prizes awarded (session 1896-97).—Prize Scholarship in Science (£120): H. E. Ridewood. Prize Scholarship in Anatomy and Physiology (£60): E. W. A. Walker. Entrance Science Scholarships: A. B. Lindesey (£60) and C. E. Ham (£35) Buxton Scholarships in Arts: T. S. Dudding (£30) and T. J. Latham (£20). Epsom Scholarship, for students of Epsom College: E. F. Fisher. Clinical Medicine: £20 scholarship, F. F. Ward; honorary certificates, C. B. Wall and A. G. Wilson. Clinical Surgery: £20 scholarship, W. E. Heilborn; honorary certificates, T. S. Novis and E. E. Prest. Clinical Obstetrics: £20 scholarship, R. W. Pearson; honorary certificates, H. L. Gregory and G. Hutcheson. Duckworth Nelson Prize: biennial (£10), T. S. Novis; honorary certificate, A. G. Wilson. Letheby Prizes: Senior (£20), H. D. Pollard; honorary certificates, O. Eichholz, H. Balean, and M. F. Reaney; Junior (£10), R. V. Dolbey; honorary certificates, C. E. Ham, T. L. Lewis, and T. S. Dudding. Sutton Scholarship (£20): E. Frazer. Anatomy and Physiology: £25 scholarship, A. F. Tregold; honorary certificates, W. R. Dunstan, J. Sherren, H. D. Pollard, H. Balean, and E. Merry. Anatomy and Biology: £20 scholarship, H. E. Ridewood; honorary certificate, C. E. Ham. Dressers' Prizes: £15 Prizes, M. F. Reaney and A. N. Symons; £10 prize, W. B. Taylor; £7 10*s.* prizes, B. C. Broomhall and R. H. N. Smith; £5 prize, H. Hodgson; honorary certificates, J. H. Sanders and E. M. Ridge. Practical Anatomy: £8 prize, A. B. Soltau; £4 prize, A. L. Matthews; honorary certificates, A. S. David, C. L. Traylen, D. Ellis, A. N. Symons, and R. Gauld.

THE SANITARY INSTITUTE.—The twenty-first anniversary of the Sanitary Institute occurred this month, and the Council arranged a commemorative dinner on the 7th, to celebrate the success that has attended the efforts of the institute to promote the public health and advance sanitary science. The Duke of Cambridge, president of the institute, was in the chair, and the company present numbered about 130, including the Earl of Stamford, Lord Kelvin, Sir Henry C. Burdett, Sir William R. Gowers, Sir Guyer Hunter, &c. Professor W. H. Corfield and Sir Douglas Galton responded to the toast of the Institute, the latter of whom said, in the course of his speech, that the Public Health Act of 1875 gave a new development to sanitation all over the country, and the institute was founded in 1876 for the purpose of advancing knowledge in all subjects bearing on public health. The earliest congress, in 1877, began with 150 members and an income of £150, but in 1897 there are 2100 members and the income is £6000. The Parkes Museum was founded in the same year as the Sanitary Institute, and the efficient action of the two institutions was largely increased by the union of them, which took place a few years later.

THE BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—The annual general meeting of this association took place on July 15th, at the Café Royal, Regent-street, W Dr C. T. Brookhouse was elected President for the ensuing year, and Dr. A. W. Thomas Vice-President. Dr. Sunderland, the retiring President, congratulated the members present on their excellent organisation, and cordially thanked the officers of the association for their kind coöperation with him during his year of office. The members and their friends to the number of fifty-one afterwards dined together, and there were present, among others, Sir John Williams, Dr. A. E. Sansom, Dr. Clement Godson, and Mr. Howard Marsh. Dr. Sansom proposed the Health of the Association, which was responded to by the hon. secretary, Dr. Major Greenwood, who, in the course of his remarks, pointed out that the flourishing condition of their association was not a little due to the supineness of the English universities in neglecting to afford reasonable means for graduation in this country. Mr. Franklin Clive and Madame George sang some excellent songs during the evening, and Dr. Haydon also assisted with some admirable violin solos.

OPHTHALMIA AT THE ELY (CARDIFF) SCHOOLS.—At the meeting of the Cardiff Board of Guardians, held recently, Mr. H. C. Ensor reported that 38 per cent. of the children at Ely Schools were affected with ophthalmia, but all the cases were of the mildest form, with the exception of 9 which were acute.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly court of directors was held on July 14th, Dr. Pollock, Vice-President, being in the chair. Three new members were elected, and the death of one was reported. The death of a widow was announced. Fresh applications were made by the guardians of two orphans for extra assistance to complete their education and cure of spinal curvature. A sum of £1206 10*s.* was voted to be distributed among the fifty widows, eleven orphans, and six orphans on the Copeland Fund. The expenses of the quarter amounted to £45 3*s.*

PRESENTATIONS TO MEDICAL MEN.—Mr. Joseph J. Cullen, L.R.C.P., L.R.C.S. Irel., medical officer, Castleknock, was on the 7th inst., at the Town Hall, Dalkey, presented by his many friends with a gold watch and chain and an artistically illuminated address as tokens of esteem.—Mr. Walter Petter, M.B., C.M. Edin., and Mr. John Smale, L.R.C.P. Lond., M.R.C.S. Eng., both of Darlington, have been the recipients of a silver inkstand and a silver eggstand respectively for their honorary instructions in first-aid to the

Digitized by Google

local classes of the St. John Ambulance Association.—Mr. Albert G. Willington, M.D. St. And., M.R.C.S. Eng., of Handsworth, who is leaving that town after practising there for fifty years, has been presented by his friends with an illuminated address and a purse of sovereigns.

THE HEALTH OF LOWESTOFT.—The Borough of Lowestoft, with a population of over 26,000, had only four zymotic deaths during the second quarter of the present year—viz.: one from diarrhœa and three from whooping-cough. The corrected death-rate for the same period was 14·8.

MEDICAL MAGISTRATE.—Mr. Patrick R. Murison, M.B., C.M. Edin., L.R.C.P. Lond., of Dundee, has been placed on the Commission of the Peace for the county of the city of Dundee.

THE Committee of the City of London Hospital for Diseases of the Chest, Victoria Park, have appointed Mr. Henry T. Dudley Ryder secretary to the institution, in place of the late Captain Storrar-Smith.

MR. C. E. M. HEY, M.R.C.S. Eng., &c., who is a Knight of Grace of the Order of St. John of Jerusalem in England, has received the honour of the French decoration of the 1st class, which has been conferred upon him at the recommendation of La Société Nationale de Sauvetage de France.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health (Scotland) Bill.

THE Government has made it known that the Public Health (Scotland) Bill is one of the measures which must be passed during the present session of Parliament.

Infant Life Protection Bill.

This measure has now passed through all its stages in the House of Lords, and in the House of Commons has been read a second time and considered by the Grand Committee on Law. It differs in many particulars from former Bills dealing with this subject, and especially in this, that it substitutes for the registration of houses a system of notification to the local authority. Its application is confined to houses where more than one infant of less than five years of age is kept for hire or reward, and it gives the local authority power of supervision and inspection. The local authority may cause to be removed to a proper place of safety a child who is found in a house so unfit or so overcrowded as to endanger health, or is in the keeping of a person who, by reason of negligence, ignorance, or other cause, is so unfit to have the care and maintenance of the child as to endanger health. When the Bill was before the Grand Committee on Law Sir William Priestley put forward the idea whether it should not be made to apply to houses where only one child is received. He did not, however, press it, and the Committee decided not to alter the provision.

London Water Question.

During the committee stage of the Metropolitan Water Companies Bill an attempt was made to get a clause inserted providing that in the case of a deficiency of water during any quarter the occupier might complain to the Railway and Canal Commission, and if the complaint was well founded the Commission might order the water company to repay the proportionate part of the rate for the days during which the supply was deficient. The clause received a considerable measure of support in different parts of the House, but the Government opposed it mainly on the ground that it went beyond the scope and intention of the Bill and on a division it was rejected by 134 to 75 votes.

London University.

At the close of the sitting of the House of Lords on Tuesday, July 20th, the Duke of Devonshire, Lord President of the Council, formally presented a Bill to make further provision with respect to the University of London.

HOUSE OF LORDS.

THURSDAY, JULY 15TH.

Lunacy Bill.

The Committee stage of the Lunacy Bill was taken at this sitting of their lordships' House. Considerable discussion arose with regard to Clause 15, which gives power to the Lunacy Commissioners to require amendment of the regulations of hospitals.—Earl Russell moved to omit the whole clause, saying that it was not necessary to give this power in the case of county or other asylums managed by large public authorities, the members of which were elective and were subject to public criticism. The Lord Chancellor took the position that instead of moving now the omission of the entire clause his lordship should have proposed some amendment by way of limiting the proposed power.—The Earl of Northbrook made the suggestion that in the case of an asylum maintained out of county or borough rates the council of the county or borough should have the opportunity of making representations against the proposed rules before they were finally approved by the Secretary of State.—The Lord Chancellor thought this reasonable and undertook to consider it.—In connexion with Clause 19 Earl Russell said that if it were enforced too rigidly at first it would press hardly upon London in the present congested state of lunacy accommodation. The London County Council, he pointed out, had 2000 lunatics under charge for whom they had no accommodation in asylums. He frankly admitted that their asylums were somewhat overcrowded, not to an extent prejudicial to health, but in a way that would be affected by this clause. The clause was reasonable in itself, but he trusted that in putting it into force some allowance would be made for the condition of things that had necessarily arisen in London.—A long debate took place with regard to the proposal in the Bill to extend to the officers and employés of lunatic asylums the provisions of the Poor-law Officers Superannuation Act of 1896, and as the outcome of it all the superannuation clauses in the Bill were withdrawn.

HOUSE OF COMMONS.

THURSDAY, JULY 15TH.

Diphtheria at Devonport.

Captain Norton asked the Under-Secretary of State for War whether, in reference to the recent outbreak of diphtheria at Devonport, by which two lives were lost, any sanitary recommendations had been made, and, if so, how far back, by the Army Medical Department or Royal Engineers respecting defects in the drainage of the Raglan Barracks; and, if recommendations were made, what were the circumstances that prevented the War Office from carrying them out.—Mr. Broderick replied that in April, 1896, the medical officer at Devonport reported that the drains of the Raglan Barracks were in an unsatisfactory state. Inquiry was made with the result that the general officer commanding submitted a comprehensive scheme involving a large cost. This had to be examined before the work could be undertaken. Money was taken in this year's estimates, and every effort would be made to press on the work as quickly as possible.

FRIDAY, JULY 16TH.

Bill for the Regulation of Dogs.

Mr. Walter Long, President of the Board of Agriculture, intimated, in reply to a question, that he hoped to be able very shortly to lay on the table a Bill for the better regulation of dogs on the lines recommended by the Departmental Committee, by which the question was recently considered. He had no intention of pressing the Bill through the House during the present session, though he would be very glad to find that the measure was generally acceptable. What he had in view was that the provisions of the Bill should be thoroughly understood by the House and the various public authorities throughout the country.

Cycle Accidents.

Sir Elliott Lees asked the Home Secretary whether, in view of the numerous police prosecutions against cyclists and the want of any definite standard as to what might be considered by the courts a lawful and safe pace for a cycle on the public highway, the Home Office would lay down and announce some regulations defining the maximum speed which they considered compatible with the public safety in town, country, and suburban districts respectively.—Sir M. White Ridley replied: I have no power to make any such regulations, and it seems clear, too, that the question what is furious or dangerous riding must depend upon the circumstances of each particular case. I may add that I made inquiry last year of the chief officers of all the police forces in England and Wales as to the number of accidents caused by cyclists in their respective districts and the remedies they suggested if the protection given by the present law seemed to them insufficient; but their replies were such as to lead me to the conclusion that no alteration in the law was required.

Experiments on Living Animals.

Mr. Weir asked the Home Secretary: (1) Having regard to the allegations made by Mr. E. Berdoe relative to the use of curare in the practice of vivisection, and to the statement of the Home Office that the experiments referred to were performed under anæsthetics, and that curare, though used, was used when the animals could not suffer pain, would he state what anæsthetics were so used; (2) was he aware that it had been held on the highest authority (Professor Claude Bernard) that an animal stupefied with morphia was still conscious to suffering, and that an animal under the influence of curare became absolutely paralysed, but was still sensible to pain though unable to show it by sound or struggle; and (3) would he state whether, in the experiments to which he referred, dogs were the animals experimented upon?—Sir M. White Ridley replied: I informed the hon. Member on Tuesday that chloroform was the anæsthetic used. My answer to the second paragraph is in the negative, and to the third paragraph in the affirmative.—Mr. Weir asked the Home Secretary if he would state the number of experiments in which curare was used in the practise of vivisection during last year and the number of licencees by whom that drug was used; and would he state the names of the licensed places where curare was used in the practice of vivisection during the year.—Sir M. White Ridley replied: I cannot see that the returns for which the hon. Member asks would serve any good purpose, and I do not propose, therefore, to call for them. Curare is prohibited by law from being used as an anæsthetic, and I am perfectly satisfied that it is not so used.

MONDAY, JULY 19TH.

Classification in Lunatic Asylums.

Mr. Weir asked the Home Secretary if he would state under what circumstances a person in a county asylum who was classified as a pauper under Section 3 of the Lunacy Act, 1891, was entitled to be classified as a private patient.—Sir M. White Ridley replied that as soon as the

Digitized by Google

asylum authorities had reasonable grounds for believing either that the patient was entitled to property which would be available for his maintenance and sufficient to render him no longer even partly chargeable to a union, county, or borough, or that an undertaking had been given by a friend or relative to provide a sum sufficient for the purpose, he would no longer be classed as a pauper.

Beri-beri in Ireland.

Mr. Patrick Aloysius M'Hugh asked the Chief Secretary to the Lord-Lieutenant of Ireland whether he was aware that the Eastern disease, beri-beri, was at present prevalent in Richmond Lunatic Asylum, Dublin; how long had this institution been afflicted with this disease, and how many nurses had suffered from it; whether medical experts, including medical gentlemen of the highest eminence connected with the institution, attributed the existence of the disease to overcrowding; was he aware that the Board of Control of lunatic asylums was responsible for the overcrowding; and would he take steps to secure that the Board of Control would not be permitted to stand in the way of necessary reforms in connexion with this asylum?—Mr. Gerald Balfour replied: Thirty-six patients and three nurses in the Richmond Asylum are at present suffering from the disease known as beri-beri. The disease first appeared in the institution about May, 1894, and continued until October, after which no fresh cases occurred. There was no outbreak in 1895, but it re-appeared in August, 1896, since when the institution has not been entirely free from it, although it almost died out in the colder months. Ten nurses in all have suffered from it—viz., seven in 1896 and three during the present year. Medical experts are of opinion that the disease was fostered by overcrowding. It is the duty of the Board of Control to provide such accommodation as is necessary in the district asylums in Ireland. In consequence of the rapid increase of lunacy in the Richmond district it was decided in 1892 to build an additional asylum for 1200 patients at Portrane, and that work is now in progress. In 1893 and 1894 temporary buildings were erected at Richmond Asylum for 298 patients, and since then accommodation has been provided for 224 patients, and further buildings are now being erected, which, it is anticipated, will make the total accommodation sufficient for the number at present in the asylum. The Board of Control are anxious to aid and promote by every means in their power any reforms necessary for the improvement of the Richmond Asylum, and works are being carried out with the view of effecting that object.

TUESDAY, JULY 20TH.

Army Medical Officers.

Colonel Denny asked the Under Secretary of State for War when the Secretary of State for War would be in a position to carry out the intention expressed by the Under Secretary when the Army Estimates were introduced last February of affording assistance to form medical messes at the large stations.—Mr. Brodrick replied that messes for medical officers had been established at the principal stations. The Secretary of State said that he would be prepared to consider any case in which it might be represented that a mess was still required.

Experiments on Living Animals.

Mr. Weir asked the Home Secretary, seeing that an animal subjected to a true anæsthetic such as chloroform was insensible to pain, would he state whether there was any reason why the use of curare in the practice of vivisection should not be forbidden, especially in view of the fact that an animal under the influence of curare had been held by the highest authority, Professor Claude Bernard, to be acutely sensible to pain, notwithstanding the fact that it was so paralysed by the drug as to be unable to express its pain by sound or struggle.—Sir M. White Ridley: As I have already stated, I am satisfied that curare is not used as an anæsthetic. There are cases, however, in which its use along with the anæsthetic is indispensable for the success of the investigation, but its use does not make the anæsthetised animal sensible to pain.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

AMENABAR, JULIUS DANIEL, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Eye Infirmary, Wolverhampton.

ASHTON, GEORGE, M.B., Ch.B. Vict., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior Resident Medical Officer to the Chorlton Union Hospitals, Withington, Manchester.

BENSON, T. S., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health by the Annfield Plain Urban District Council.

BIRD, JAS. B., M.B., C.M. Edin., has been appointed Assistant Physician to the Cumberland Infirmary, vice R. D. Helm.

BROUGH, DANIEL, M.B., C.M. Edin., has been appointed House Surgeon to the Bridgwater Infirmary, Bridgwater.

COWIE, WM., M.B., C.M. Aberd., has been appointed Assistant Medical Officer to the Plumstead Infirmary, Kent.

DAVIDSON, PERCIVAL, M.B., B.S. Durh., has been appointed Senior House Physician to the Royal Infirmary, Newcastle-on-Tyne.

FLEMING, R. A., M.D., F.R.C.P. Edin., has been appointed one of the Pathologists to the Edinburgh Royal Infirmary, vice R. F. C. Leith.

GOLDSMITH, F., M.B., Ch.B. Adel., has been appointed Medical Officer at Port Darwin, South Australia, vice L. S. O'Flaherty.

GOSSE, WILLIAM, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H. Camb., has been appointed a Public Vaccinator for the Sittingbourne District of the Milton Union.

HOPE, E. W., M.D. Edin., D.Sc. (Public Health), B.Sc., L.R.C.P. Lond., has been appointed to a Professorship of Public Health, University College, Liverpool.

KINGDON, WILFRED R., M.B., B.S. Durh., has been appointed Resident Medical Officer of the Woodlands Asylum, Ticehurst, Sussex.

LEE, W. H., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed House Physician at the Royal Hospital, Sheffield.

LEITH, R. F. C., M.B., C.M. Edin., F.R.C.P., has been appointed an Assistant Physician to the Edinburgh Royal Infirmary.

LLOYD, JORDAN, M.B., F.R.C.S., has been appointed Honorary Consulting Surgeon to the West Bromwich District Hospital, vice C. Pemberton, deceased.

MARTIN, A. J., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed an Honorary Acting Physician to the Walsall and District Hospital.

MASON, T. P., M.B. Lond., F.R.C.S. Irel., has been appointed a Consulting Physician to Mercer's Hospital, Dublin.

PARTINGTON, WM., M.B., C.M. Glasg., has been re-appointed Medical Officer of Health by the Tunstall Urban District Council.

PATTINSON, J., has been appointed Public Analyst for the Borough of Sunderland by the Sunderland Town Council.

SIMPSON, W. P., M.B., C.M. Edin., has been appointed Medical Officer for the Pelham Lounds Sanitary District of the Boston Union.

STOKER, H., L.K.Q.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health for Melbourne, Victoria, Australia.

RENNEY, HENRY, M.D. Durh., D.P.H., has been appointed Honorary Deputy Medical Officer of Health by the Sunderland Town Council.

ROWELL, WILLIAM HENRY, M.B., B.S. Durh., has been appointed Junior House Physician to the Royal Infirmary, Newcastle-on-Tyne.

VERNON, WM., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Bitton Sanitary District of the Warmley (out-relief) Union, vice G. S. D. Willett.

WHITMARSH, R. P. H., M.D. Brux., L.R.C.P., L.R.C.S.E., L.S.A. Lond., has been appointed Resident House Physician to the Hospital for Consumption, Brompton.

WILLIAMS, JOHN HUMPHRY, M.D., C.M. Edin., has been re-appointed Medical Officer of Health for the Borough of Flint.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITALS, Manchester.—Resident Senior House Surgeon. Salary £80, with board and washing.

BIRMINGHAM CITY ASYLUM.—Junior Assistant Medical Officer. Salary £80 a year, with board, lodging, and washing.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant (non-resident) for three months. Honorarium of thirteen guineas will be given.

BOSCOMBE HOSPITAL, Shelley-road, Boscombe, Bournemouth.—House Surgeon, unmarried. Salary £60 (exclusive of wine and beer), lodging, and washing.

BRADFORD UNION WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100 per annum, with prescribed rations, washing, and apartments in the Workhouse. Applications to the Clerk to the Guardians.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House Surgeon. Rooms, coals, and lights provided.

CHILDREN'S HOSPITAL, Nottingham.—House Surgeon (non-resident) for six months. Salary at the rate of £100 per annum.

CUMBERLAND INFIRMARY, Carlisle.—House Surgeon for one year. Salary £70 per annum, with board, lodging, and washing.

GUEST HOSPITAL, Dudley.—Resident Medical Officer. Salary £100 a year, increasing £10 a year to £120, conditionally, with board, residence, attendance, and washing.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Junior Resident Medical Officer for six months. Salary at the rate of £50 per annum, with board, lodging, and washing.

HUNTINGDON COUNTY HOSPITAL, Huntingdon.—House Surgeon. Salary £50.

Digitized by Google

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London, N.W.—Assistant Resident Medical Officer for four months. Salary at the rate of £50 per annum, with board, residence, and washing.

QUEEN'S COLLEGES, Ireland.—Professorship of Medicine in the Queen's College, Cork. Applications to the Under Secretary, Dublin Castle.

ROTHERHAM HOSPITAL AND DISPENSARY.—House Surgeon for three years. Salary 100 guineas, with board, lodging, and washing.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board, and washing.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—Assistant House Surgeon. Board, residence, and laundry provided.

STOCKPORT INFIRMARY.—House Surgeon. Salary £100 a year, with board, washing, and residence. Also Junior Assistant House Surgeon for six months. Honorarium at the rate of £24 per annum, with residence, board, and washing.

STOURBRIDGE DISPENSARY.—House Surgeon and Secretary. Salary £120 a year, increasing £5 annually to £130, with furnished rooms, coal, and gas, and an allowance of £25 for travelling expenses.

SUNDERLAND BOROUGH ASYLUM, Ryhope, Sunderland.—Resident Clinical Clerk for six months. Board and lodging provided, with a nominal salary.

Births, Marriages, and Deaths.

BIRTHS.

ASHWELL.—On July 18th, at Mansfield-road, Nottingham, the wife of H. G. Ashwell, M.R.C.S., L.R.C.P., of a son.

GLOSTER.—On July 15th, at Upper Phillimore-place, Kensington, the wife of J. C. Gloster, M.B., M.Ch., of a daughter.

HEATH.—On July 14th, at Hagley-road, Edgbaston, Birmingham, the wife of A. Douglas Heath, M.D., of a daughter.

HOUGHTON.—On July 18th, at East Looe, Cornwall, the wife of Leonard F. Houghton, M.R.C.S., L.R.C.P., of a son.

MILLER.—On July 18th, at 747, Commercial-road, Limehouse, E., the wife of Arthur W. Miller, M.B., C.M., of a daughter.

NEALE.—On July 19th, at Truro Villa, Nevil-road, Bishopston, Bristol, the wife of Albert E. Neale, M.B., B.S., of a son.

OLIVER.—On July 19th, at Westdene, Maidstone, the wife of Charles Pye Oliver, M.D., of a son.

SMITH.—On July 14th, at Warkworth House, S. Thomas, Exeter, the wife of Thomas Smith, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BLACKER—MARRIOTT.—On July 7th, in the Cathedral at Exeter, by the Rev. Canon Edmonds assisted by the Rev. William David, Arthur Barry Blacker, M.D., B.S., of 15, West Eaton place, S.W., son of the late Rev. Maxwell J. Blacker, M.A., and grandson of the late Lieut.-Colonel Valentine Blacker, C.B., Surveyor-General of India, to Zaré Elizabeth Marriott, widow of George Herbert Marriott, of Orotava, Teneriffe.

COWAN—GRANT.—On July 14th, at St. George's, Dunster, John James Cowan, M.B., C.M., second son of Inspector-General M. W. Cowan, M.D., R.N., of Leigh Lodge, Worcester, to Gertrude (Bal), only daughter of Vice-Admiral John F. G. Grant, of Alcombe, Somerset.

JEFFREYS OWEN—JONES.—On July 7th, at St. Mary's, Bath, R. Jeffreys Owen, L.R.C.P. Lond., M.R.C.S., of Llandovery, to Mary Elizabeth, only daughter of the late George Jones, Esq., J.P., of Ystrad, Llandovery.

LEMON—WHITE.—On July 17th, at St. Paul's, Edinburgh, Edward Henry Lemon, M.R.C.S., L.R.C.P., D.P.H., of Lee, Kent, to Adelaide Theresa, only daughter of the late Robert White, Abercromby-place, Edinburgh.

REID—BRUCE.—On July 15th, at Strathpeffer Church, by the Rev. Jas. Fraser, M.A., minister of Blair-Atholl, assisted by Rev. John M'Gilchrist, B.D., minister of Fodderty, Wm. Reid, Physician-Superintendent of the Aberdeen Royal Lunatic Asylum, to Grace Garden, eldest daughter of Wm. Bruce, M.A., M.D., LL.D., The Castle, Dingwall.

DEATHS.

BUCKNILL.—On July 19th, at Bournemouth, Sir John Charles Bucknill, M.D., F.R.S., aged 79.

ROBERTSON.—On July 15th, at Buxton, William Henry Robertson, M.D., aged 86.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

THE PROFESSORSHIP OF MATERIA MEDICA AT GLASGOW.

WE have received the testimonials in favour of "Robert Bell, M.B., M.D.," for the chair vacant by the death of Professor Charteris, and we advise Dr. Bell in his own interests to edit his testimonials before approaching Lord Balfour of Burleigh on the strength of them. "M.B., M.D.," is not a usual affix to a physician's name, while the writer of the private letter and the testimonial on page 18 (both of which are published) was never a baronet and is now dead. Testimonials, when containing no errors, are looked at sufficiently askance nowadays, so much have they been abused; but testimonials to which an incorrect statement is appended will prove of negative value.

A WARNING.

To the Editors of THE LANCET.

SIRS,—Will you permit me space in the interests of the profession to utter a warning note to any professional brethren who may be contemplating appointments abroad? First, let them be sure that what appears a large salary to them at home is of the same relative value in the country whither they propose to go. Secondly, have everything reduced to writing in such form as to be cognisable by the courts of both countries. Thirdly, if it be the United States have an agreement signed in England before starting and embodying a clause to the effect that a new agreement embracing the same terms shall be executed in America on landing. Fourthly, insist that the facts upon which any promised advantages are based shall also be reduced to writing. Fifthly, do not take any "collateral advantages" as part remuneration. Get money value for your services and pay cash for your collateral advantages when you have found out what they are worth. Lastly, insist upon a clause securing your return passage in any case. These suggestions are the result of my own experience. Let me emphasise and illustrate them by two examples.

In 1893 I left England "with my household gods" as medical officer to the Lower California Development Company, operating in Lower California, Mexico. The salary was only £100 per annum, but as collateral inducements I was offered private practice in a country whose lovely climate, cheap living, natural advantages, future prospects as a new Riverside at fruit-farming were attracting numerous thriving investors. Moreover, there was an outlook for my boy in the acquirement on what would have been very advantageous terms (had the acquisition proved worth anything at all) of a fruit ranche. I was told of fenced and planted farms, of a large territory under irrigation by nine miles of pipe line, of frequent shipping communication by the company's steamers, of a railway in construction to connect the place with the United States, "the first seventeen miles now being open for traffic," and numberless other things tending to sink my £100 per annum into insignificance by the side of the collateral advantages. I found—an arid wilderness of leagues of sand and cactus, without foliage or available water, and occupied by some six or eight officials, with a few settlers—chiefly refugees from justice—and Mexican peasants—thriftless and quarrelsome, the whole numbering perhaps seventy, certainly not more. The frequent steamers ran once a fortnight, so that one could not go away without leaving for two weeks. The climate (on the coast) consisted chiefly of wind and sandstorm from sunrise to sunset, while the railway, "now open for traffic," had never run but one train—viz., two years before for Government inspection, which had resulted in rejection. The line began nowhere, passed by nowhere, and ended abruptly in a Sahara. There were three or four fenced ranches, not more, which had been abandoned mostly by their owners, and, save as a source of tax income to the Mexican Government, were of no value to anyone. Finally, one was imprisoned there—"anchored," as the secretary of the company euphemistically phrased it—almost as securely as though one had been a prisoner on a barren rock in mid ocean. If any corroboration be needed of my account of this place it can, doubtless, be furnished by my predecessor there, Mr. H. W. Newton, formerly, I believe, of the Middlesex Hospital.

Now for my second experience. I escaped from Lower California, after fifteen months' penal servitude, a sadder (but I regret to say not a wiser) man. After twelve months in Los Angelos trying, though with insufficient capital yet with good prospect of ultimate success, to work up a practice, I was informed that the Mountain Mines, Limited (now the Mountain Copper Company, Limited), an English syndicate operating in Northern California, wanted a resident physician. After some correspondence I went up there to investigate and be investigated. I found what undoubtedly bade fair to be the prosperous undertaking into which it has subsequently developed. The manager was essentially an English—or rather Scottish—gentleman, the staff congenial, and the surroundings and conditions apparently conducive to a life worth living, while for a man devoted to his profession there was every promise of good practice (especially surgical) as things developed. The following terms were agreed upon between the manager and myself (subject to confirmation in London), and were taken down by me in writing at his dictation. The salary I knew to be less than half that customary in this country, where the lowest professional fee is $2.50 or 10*s*. But then, there were splendid opportunities in the future for practice, which is always allowed in this country, and other "collateral advantages." 1. Salary, undetermined. I asked for a minimum of $150 a month. The manager thought the company would not give more than $100 or at most $125. (They had been paying a local practitioner in Redding, seven miles off, $100 a month for a bi-weekly visit and attendance on urgent summons, while he enjoyed an excellent practice at home). 2. Board free for myself and at $15 a month for each member of my family. 3. A house to be built for me rent free, furnished as to all essentials by the company, and with free fuel, light, and attendance. 4. Such private practice as could be undertaken without neglecting official duties and the right to charge fees for attendance on employés' families. In due course I was offered the appointment if I would accept a salary of $125, which I did. This, with free board at $15, made a nominal $140. As the manager was anxious to start on the erection of a hospital (which was not, however, begun for nearly twelve months) I started up by request four days later and, without waiting to sign any agreement, as soon as I had given up my house and office, sold my belongings, &c. I expected, of course, to have at least a one or two years' agreement on the terms stated presented to me for signature on arrival. When I spoke about this later, to my astonishment I was told "this company does not give agreements to its staff." However, as I found all the other officers in the same case, and no one apparently with any misgiving, I had no alternative but to be content. My house, it is true, made no progress for various reasons; but I was given furnished quarters rent free (a bedroom and a sitting-room), and all the other clauses were duly fulfilled. Some months later, two directors came out. They calmly interdicted private practice, scoffed at the idea of charging fees to families, and insisted on their attendance being included in the duties of my salary, and charged me rent for my quarters (reduced to a bedroom only), making the same one month retrospective. When I appealed to the terms on which I came, and which the manager was willing to substantiate, they calmly informed me that as my salary was paid monthly, my tenure was only a monthly one. They did not intend to fulfil those terms; they could buy lots of doctors as the steamships did for £10 a month, and if I did not like it I could quit at any time. Again I was trapped; I had given up all and had nothing to go to, so perforce had to stay. Since then the works have increased. Three smelters, an extensive mine, and eleven miles of mountain railroad employ upwards of 600 men, many with families. The work exacted from the doctor here is the most arduous I have ever seen or heard of, to say nothing of the responsibility involved. Yet his pay is only $140 a month, out of which not only board but even rent for his quarters in hospital (a house surgeon charged rent!) is exacted. Compare this with the $100 a month and upwards paid to various classes of mechanics and $50 a month and upwards for common labour. Why, the work here would easily earn at the minimum fees authorised by the Medical Society and adopted by all reputable practitioners $1500 a month. On the calculation of a three months' basis it is actually pay for journeys, visits, consultations, operations, dressings, and confinements, of under 19 cents (9½*d*.) each! Further, the company has issued a ukase that no member of its staff is to do any business of any kind outside the company's duties; so that if one should see a profitable investment, which is not unlikely in a great mining country, one is debarred under pain of dismissal from availing oneself of it. Finally, a few months ago, the board suggested that the doctor should do private practice and pay the fees to the company, the directors reserving the right of deciding what portion of these fees, "if any," they should return to their doctor. Not having arrived at the stage at which I am prepared to be guilty of "infamous conduct in a professional respect" by complying with such an outrageous demand, needless to say I declined. Two days ago, on grounds not personal but of public policy professionally, I handed in my resignation, and I quote this with the other instance as a warning to all who may contemplate taking up company appointments abroad to trust nothing to either the truthfulness as to matter of fact or the scrupulousness as to matters of agreement of companies or their officials. Rather, have everything—promises, representations as to actually existent conditions, limitations of freedom, &c.—in black and white, duly signed, sealed, and delivered in such a way as to be cognisable by the courts of both countries, and above all, insist on a clause guaranteeing your return passage.

As a St. Mary's man, I am known to most of the authorities there, who will be able to testify whether my remarks are *primâ facie* worthy of credence or not. As to my service here, I am content to leave my record in the hands of the late manager, Mr. Alex. Hill, C.E., whose retirement only took place this month.

I am, Sirs, yours faithfully,

KENNETH W. MILLICAN, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Edin.

Keswick, Cal., June 18th, 1897.

W.H.F. (South Molton).—We do not know the meaning of A.K.S. Possibly it is a mistake for A.K.C. If so, the letters mean "Associate of King's College," which is not a medical qualification, but somewhat equivalent to the B.A. of an ordinary university.

PREVENTION OF VENEREAL DISEASES.

WE are obliged to our Sydney, N.S.W., correspondent for his suggestion. Without discussing the possible efficacy or not of his proposal we fear that its application would be attended with such difficulties and objections as to make it impracticable to carry out.

J. W.—(1) We cannot say. (2) We do not prescribe or suggest treatment. (3) The degree is a good one, though we cannot attempt to classify it as harder or easier of attainment than that of the other universities named. (4) Yes.

R. W—Our correspondent is advised not to apply for the vacancy. The profession in the neighbourhood are right to resent such methods.

One in Doubt need be in doubt no longer. The operation is impossible.

F. D. B.—We think so.

LUPUS NECROGENICUS AND LUPUS VERRUCOSUS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers supply me with any information concerning the literature of lupus necrogenicus or lupus verrucosus?

I am, Sirs, yours faithfully,

Blaenavon, Mon., July 19th, 1897. J. THOMSON.

Digitized by Google

A MYSTERIOUS QUESTION.

To the Editors of THE LANCET.

SIRS,—Please insert the following in next week's LANCET:—"Is there any cure for scarlet fever dropsy beginning in ancles and going gradually up body. If so, what will cure it? Bornall please answer (to Besom)." Yours truely,

F. R.

*** We give the insertion which is asked; perhaps our correspondent will now give us a literal "construe" of the communication.—ED. L.

Cue.—The circumstances of the case dictate the answer. If the bicycle is to be used entirely for the conduct of the principal's practice, or for its development, it seems to us to be his duty to purchase it and keep it in order. If the assistant's work has previously been got through without a bicycle, and there is no suggestion that he should do more with a bicycle, the principal may look upon the purchase of a machine as a luxury in which he does not personally participate, and may therefore be just in thinking that he ought to be at no expense in the matter. Probably both parties would benefit by the purchase of a bicycle; therefore some arrangement might be arrived at whereby the expense would be shared and the use of the machine be not so strictly limited to professional purposes.

Celeste.—In the proper circumstances the treatment is radical. Our correspondent's medical man could give her all information.

Mr. G. Leonard Hill.—We do not remember publishing any cases of the sort to which our correspondent is seeking reference.

"COOLING POWDERS."

AN inquest was recently held by Dr. Wynn Westcott on the body of a boy aged six years who was taken ill on June 27th. His mother gave him a cooling powder, but the child died next day. Mr. A. S. Dawson, in giving evidence, said that he found the child dead on his arrival on the 28th. This was the third case to which he had been called after the administration of one of these powders. They contained tartar emetic, and were sold quite promiscuously. The drug was a very depressing one, and the examination of the child's body showed that he had died from syncope following pneumonia. Death, he believed, was accelerated by the very hot weather and the depressing effect of the drug. A juryman remarked that it was a shame that poison could be sold to anybody who asked for it; but the coroner said that as the powders in question were a patent medicine and bore a government stamp they evaded the Poisons Act. The Medicine Stamp Act ought to be repealed. It is simply a premium upon lying and murder; for most patent medicines are useless, and many of them are harmful. We have said over and over again that all proprietary and patent medicines should only be sold in bottles, or packages, or boxes with the full formula legibly printed thereon. Then, if people still like to pay 4*s.* 6*d.* for a halfpennyworth of nitre or 11*s.* 6*d.* for a grain of perchloride of mercury, they can do it, but at present adventurers flourish unchecked, and it is quite time something was done to stop them, even though "commercial enterprise" be interfered with.

Dr. Thomas Laird is thanked for his communication. We will endeavour to ascertain if any practical experience of the treatment can be published.

J. S. will find the lecture printed in full in THE LANCET of June 24th, 1893.

E.P.P.—We cannot trace the receipt of the communication in question.

ITALIAN FOUNDLING HOSPITALS.

THE recent appalling revelations of the mortality in these institutions—revelations evoked last May in the Camera dei Deputati, when the mismanagement of the Neapolitan Brefotrofio was under discussion—have led to the nomination of a committee of inquiry into the whole subject—viz., the illegitimacy which gives rise to the system of foundling hospitals, the provocatives of that illegitimacy, and the distribution and administration of the hospitals themselves. The constitution of the committee is notably strong, made up as it is of high medical authorities like the Senators Durante, Tommasi-Crudeli, and G. Bianchi; the members of Parliament, Silvestro Piccardi, Professor Angelo Celli, F. Fede, U. Levi, P. Bertarelli; the commendatore L. Bodio; the engineer G. Speroni (President of the Provincial Council of Como), and the advocate Raffaele Perla To those of our correspondents who have written to us for information as to these hospitals we may recommend the committee's report (shortly to be made *publici juris*) as a document possessing all the guarantees of impartiality, thoroughness, and accuracy. For such of them, moreover, as require that information with the least delay possible we know of no better source than the "Atti Parliamentari" for the latter half of May, which, as the Italian equivalent to our own Hansard, may be procured through any bookseller. The Neapolitan Brefotrofio, we may add, is not under religious management.

THE CLIMATE OF CORSICA.

To the Editors of THE LANCET.

SIRS,—Would any of your numerous readers be kind enough to inform me as to the salubrity of the climate of Corsica?

I am, Sirs, yours faithfully,

July 18th, 1897. O. H.

A Practitioner of Twenty-five Years' Standing will agree with us that no parent's opinion concerning the reasons for a son's failure in examination will ever have public weight. Therefore, though in sympathy with the letter, we have judged that no useful object would be served by printing it.

A. H., M.B.—THE LANCET of Sept. 12th, 1896 (page 769) contains the information our correspondent requires. It is too long for us to transcribe here. There is an agitation in Italy to place that country in a position towards foreign medical men similar to that adopted by France and Switzerland.

Inquisitor has forgotten to enclose his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (28th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (29th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (31st).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

During the week marked copies of the following newspapers have been received:—*Newcastle Weekly Chronicle, Salisbury Journal, Acton Gazette, Dundee Advertiser, Glasgow Evening Herald, East Anglian Daily Times, Birmingham Gazette, Brighton Gazette, Hull Daily Mail, Huddersfield Chronicle, North British Daily Mail, South Wales Daily News, Manchester Guardian, Times of Ceylon, Eastern Morning News, Liverpool Courier, Scotsman, Citizen, Bradford Observer, Derbyshire Times, Yorkshire Post, Architect, Western Mercury, Tottenham Herald, Bath Chronicle, Tamworth Mercury, New York Herald, Builder, Liverpool Daily Post, Sydney Morning Herald, Times of India, Pioneer Mail, Montreal Star, North-Wilts Herald, Leicester Post, Evesham Journal, Herald of Wales, Wolverhampton Chronicle, Leeds Mercury, Halifax Guardian, Portsmouth Times, Carnarvon Herald, Devon Weekly Times, Sussex Daily News, Sheffield Telegraph, Bristol Mercury, Sanitary Record, Reading Mercury, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Hertfordshire Mercury, City Press, Surrey Advertiser, Mining Journal, Local Government Journal, Christian World, Oswestry Advertiser, Sevenoaks Chronicle, Science Siftings, Eastern Counties Times, Derby and Chesterfield Reporter, Perthshire Advertiser, Melton Mowbray Mercury, West Middlesex Herald, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Messrs. Arnold and Sons, Lond.; Anglo-Swiss Condensed Milk Co., Ltd., Secretary of; Ancoats Hospital, Manchester, Secretary of; Dr. S. A. Arany, Kassa, Hungary; Anderson's College Medical School, Glasgow, Secretary of.

B.—Dr. E. Baily, Oban, N.B.; Messrs. Burroughs, Wellcome, and Co., Lond.; Brussels Medical Graduates' Association, Lond., Hon. Secretary of; Borough of Lowestoft, Medical Officer of Health of; Dr. E. M. Brockbank, Manchester; Mr. A. Hinckes Bird, Lond.; Dr. John Bruce, Rothes; Dr. P. F. Bergmann, Wiesbaden; Boscombe Hospital, Bournemouth, Hon. Secretary of; Mr. C. Birchall, Liverpool; Mr. Banks, Bolton; Dr. L. S. Beale, Lond.; Birmingham City Asylum, Medical Superintendent of; Dr. L. Buchanan, Glasgow; Messrs. Burgoyne, Burbidges and Co., Lond.; Herren Breitkopf and Härtel, Leipzig; Dr. E. T. Blank, Rovio, Switzerland; Mr. F. D. Bennett, Lond.; Sir F. Bateman, Norwich; Mr. Blackett, Lond.; Birmingham and Midland Hospital for Skin Diseases, Hon. Secretary of; Dr. Bagshawe, St Leonards-on-Sea.

C.—Dr. F. Graham Crookshank, Lond.; County of Chester, Medical Officer of Health of; Celeste, Newby Bridge; Mr. E. Brudenell Carter, Lond.; Mr. John Cahill, Lond.; Dr. J. A. Clough, Leeds; Messrs J. and A. Churchill, Lond.; Condal Waters, Ltd., Managing Director of; Mr. T. Cooke, Lond.; Messrs. Coxeter and Son, Lond.; Children's Hospital, Nottingham, Secretary of; Cortland Wagon Co., Lond; Mr. H. Connop, Reading; Mr. A. Court, Birmingham; Comaltana Wine Co., Heckmondwike; Dr. A. T. Cabot, Boston, U.S.A.; Cumberland Infirmary, Carlisle, Secretary of.

D.—Mr. R. Dunstan, Lond.; Herr E. Dieterich, Helfenberg.

E.—Messrs. Eason and Son, Dublin.

F.—Mr. W. H. Fuke, South Molton.

G.—Dr. E. Guntz, Dresden; Guest Hospital, Dudley, Secretary of; Mr. M. Gloag, Perth; Messrs. Gordon and Gotch, Lond.; Great Eastern Railway, Lond., Manager of; Government of Hong Kong, Acting Colonial Surgeon of; Dr. J. B. Gillam, Bromyard; Griffin, Lond.

H.—Mr. Otto Holst, Eastbourne; Mr. G. Leonard Hill, Dursley; Mr. C. H. Hulsh, Lond.; Messrs. Hertz and Collingwood, Lond.; Mr. R. Hill, H.M.S. *Victory*, Portsmouth; Mr. H. W. Hoskyns, Lond.; Mr. R. Hill, Portsmouth; Health Committee, Greenock, Medical Officer of; Hospital for Diseases of the Throat, Golden-square, Secretary of; Mr. E. Hancock, Southam.

I.—Messrs. Ingram and Royle, Lond.; Inquisitor, Lond.

J.—Dr. J. E. Jones, Dolgelly; Mr. John Jones, Liverpool; Dr. A. B. Judson, New York.

K.—K., Newcastle-on-Tyne; Mr. B. Kühn, Lond.

L.—Mr. P. G. Lewis, Folkestone; Dr. T. Laird, Heywood; Mr. H. J. Lawrence, Cape of Good Hope; Ledger, Lond.; Dr. P. Leech, Halifax; Dr. T. G. Lyon, Lond.

M.—Dr. P. McDougall, Sydney, N.S.W.; Mr. Kenneth W. Millican, Cala, U.S.A.; Dr. P. W. MacDonald, Dorchester; Mr. J. W. McVitie, Manchester; Medical Department, Admiralty, Director General of; Mr. R. S. Miller, Windsor; Dr. C. D. Musgrove, Penarth; Medical Society of Victoria, Melbourne, Secretary of; Messrs. Macmillan and Co., Lond.; *Medical Council*, Philadelphia, U.S.A., Editor of.

N.—Nightingale Fund, Lond., Secretary of; National Telephone Co., Lond.; North Riding Infirmary, Middlesbrough, Secretary of; Norfolk and Norwich Hospital, Norwich, Secretary of; Northern Optical Co., Bolton.

O.—Mr. W. Overend, Edmonton; Mr. Edmund Owen, Lond.

P.—Dr. E. P. Philpots, Bournemouth; Mr. A. G. Parrott, Bristol; Phœnix Food Co., Dublin; Misses E. and P. Putz, Lond.; Patella, Lond.; Purchaser, Lond.

R.—Dr. R. R. Rentoul, Lond.; Royal National Hospital for Consumption, Ventnor, Secretary of; *The Rock*, Editor of; Royal Albert Hospital, Devonport, Secretary of; Royal Surrey County Hospital, Guildford, Assistant Secretary of, R., Lond.; Messrs. B. Reece and Son, Llanelly; Mr. H. Rainbird, Saxleby; Messrs. Reynolds and Branson, Leeds; Messrs. Robertson and Scott, Edinburgh; Rotherham Hospital and Dispensary, Secretary of; Dr. H. Robarts, St Louis, U.S.A.; Mr. H. A. Roechling, Leicester; Mr. Bernard Roth, Lond.

S.—Dr. W. J. Simpson, Calcutta; Mr. G. F. Shann, Stourbridge; The Bishop of Stepney; Dr. P. S. Smith, Aberdeen; Sunderland Asylum, Ryhope, Clerk of; Stourbridge Dispensary, Hon. Secretary of; Mr. W. H. Smith, Lond.; Messrs Street Bros., Lond.; Société Royale des Sauveteurs, Lond.; Mr. E. Stanford, Lond.; Stockport Infirmary, Secretary of; Messrs. Street and Co., Lond.

T.—Mr. J. Thomson, Blaenavon, Mon.; Messrs. Tucker and Son, Totnes.

U.—University College, Liverpool, Dean of.

W.—Sir John Williams, Lond.; Dr. T. O. Wood, Lond.; Messrs. W. M. Wills and Co., Lond.; Mrs. E. Wright, Woodside; Westminster Hospital Medical School, Secretary of; W. B., Lond.; Wilts County Asylum, Clerk of.

X.—X. Y. Z., Liverpool.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. E. Adam, Liverpool; A. F., Lond.; Ashwood House, Kingswinford, Proprietors of; A. M. Z., Lond.; A. B., Lond.; Dr. J. Attlee, Lond.; Aspirator, Lond.; Dr. G. Agnew, Lurgan; Æsculapius, Lond.

B.—Dr. M. Beattie, Gotham; Bradford Infirmary, Secretary of; Mr. S. Boyd, Lond.; Mr. M. L. Bensusan, Lond.; Dr. J. I. B. Berkart, Lond.; Mr. L. A. Bidwell, Lond.; Mr. E. S. Bishop, Manchester; Mr. B. Brown, Huddersfield; Be Traish, Edinburgh; Dr. Bullimore, Falmouth; Brougham, Lond.; Mr. H. E. H. Bigg, Lond.; Mr. G. S. L. Baines, Jarrow-on-Tyne; Dr. J. L. Bond, Ukiak City, U.S.A.

C.—Mr. W. F. Cholmeley, Wolverhampton; Messrs. Cuffe Bros., Dover; Mr. H. Cripps, Lond.; C. J., Lond.; Church Stretton Private Asylum, Secretary of; Messrs. A. Coben and Co., Lond.; Mr. J. Carter, Lond.; Mrs. Clare, Baden Baden; Caustic, Lond.

D.—Mr. J. T. Davenport, Lond.; Mr. G. H. Divan, Churchtown; Mr. L. B. Dhargalker, Bombay, India; Dr. J. C. Dunu, Lond., Durham, Lond.; D. R., Bristol; Mr. R. Davis, Lond.; Mr. A. Duprey, Trinidad.

E.—Dr. F. P. Elliott, Walthamstow; Evelina Hospital for Sick Children, Lond., Secretary of.

F.—Miss M. A. Fergusson, Broughty Ferry; Fides, Lond.; F. W. J., Lond.; F. E. L., Brighton.

G.—Dr. C. G. Gibson, Launceston; Miss Gower, Boscombe; Grimsby News Co., Proprietors of; Mr. H. E. Girdlestone, South Malvern; Dr. R. Gondoux, Villeneuve; Mr. Gibbs, Redditch; G. A. E. I., Pontypridd; Dr. B. Griffiths, Mardy; Dr. J. Gillett, Andover; Gann, Newcastle-on-Tyne.

H.—Hereford General Infirmary, Secretary of; Hospital for Women, Soho-square, Secretary of; Harvard Co., Lond.; H. B., Lond.; Dr. D. L. Hubbard, Lynton; Mr. J. Heywood, Manchester.

I.—Iona, Barnsley.

J.—Mr. C. James, Avebury; J. H., Lond.; Mr. J. K. Jones, Llanrhaiadr; J. M., Lond.

K.—Dr. C. Kidd, Bromsgrove; Dr. H. Kerr, Stone; Kilpatrick, Lond.; Prof. S. Kitasato, Tokyo. Dr. S. Kontoleon, Piraeus, Greece; Messrs. Krohne and Sesemann, Lond.

L.—Mr. A. Little, Walthamstow; Leeds General Infirmary, Treasurer of; Messrs. Lee and Nightingale, Liverpool; Locum Tenens, Devoran; Mr. H. K. Lewis, Lond.

M.—Mr. W. Mettam, Darnell; Mac, Lond.; Mutual Life Assurance Co., of New York, Lond., General Manager of; Dr. J. R. Milsome, Addlestone; Dr. A. W. Miller, Lond.; Mutual, Lond.; Messrs. J. Maythorn and Son, Biggleswade; Medicus, Luton; Med. Officer, Stronsay; M. P., Luton.

N.—Mr. Newman, Hastings; North Staffordshire Infirmary, Stoke-upon-Trent, Secretary of; Messrs. Newton and Co., Lond.; Norsham, Lond.; Dr. H. S. Nutting, Warsop; Nucleus, Lond.

O.—Mr. R. J. Owen, Bridge of Allan; Mrs. S. Oakes, Everton, Liverpool; Omega, Lond.; Mr. W. P. Owen, Aberystwyth.

P.—Mr. F. G. Penrose, Dublin; P., Lond.; P. P., Lond.

Q.—Questor, Lond.; Q. C., Buxton.

R.—Mr. R. Roberts, Llanddeusant; Messrs. H. and J. Reading, Lond.; Messrs. Roberts and Co., Lond.; Royal South Hants Infirmary, Southampton, Secretary of; Rest, Lond.; Riverside, Lond.; R. L., Lond.

S.—Dr. W. C. Sullivan, Lond.; Springfield House Asylum, Bedford, Medical Superintendent of; Senex, Lond.; Messrs. Squire and Sons, Lond.; Sheffield School of Medicine, Secretary of; St. John Ambulance Association, Secretary of; Messrs. W. H. Smith and Son, Birmingham; Soloid, Lond.; Mrs. Saunders, Liverpool; Surgeons' Hall, Edinburgh, Secretary of; Seaside, Lond; Salutaris, Lond.; Surgeon, Teddington; Messrs Shiell and Small, Dundee; Smedley Hydropathic Co., Matlock, Secretary of; Suburb, Lond.

T.—Dr. Trevelyan, Leeds; Mr. L. A. Tallerman, Lond.; T. G., Lond.; Mr. J. Thin, Edinburgh; Mr. J. Thomarson, Lond.

U.—Unwin, Lond.

V.—Victoria Hospital for Sick Children, Chelsea, Secretary of.

W.—Dr. Whittaker, Lond.; Messrs. Wright, Dain, and Co., Birmingham; Mrs. Woodd, Lond.; West End Hospital for Diseases of the Nervous System, Hon. Secretary of; Wantage Union, Clerk of; Mr. E. S. Warburton, Treherbert; Dr. E. Wakelam, Oldham; Mr. T. B. Whitelaw, Glasgow; W., Lond; Western General Dispensary, Lond., Matron of.

Inaugural Address

ON

MEDICAL GEOGRAPHY AS AN AID TO CLINICAL MEDICINE.[1]

Delivered at the First Meeting of the Isle of Man Medical Society on Dec. 4th, 1896,

BY ALFRED HAVILAND, M.R.C.S. ENG.

MR. PRESIDENT AND GENTLEMEN,—I thank you very cordially for the honour you have done me in asking me to deliver the inaugural address on the occasion of the first meeting of the Isle of Man Medical Society. At the same time allow me to congratulate the founders of an institution which in the sequel is calculated to promote the advancement of science among those practising in your island.

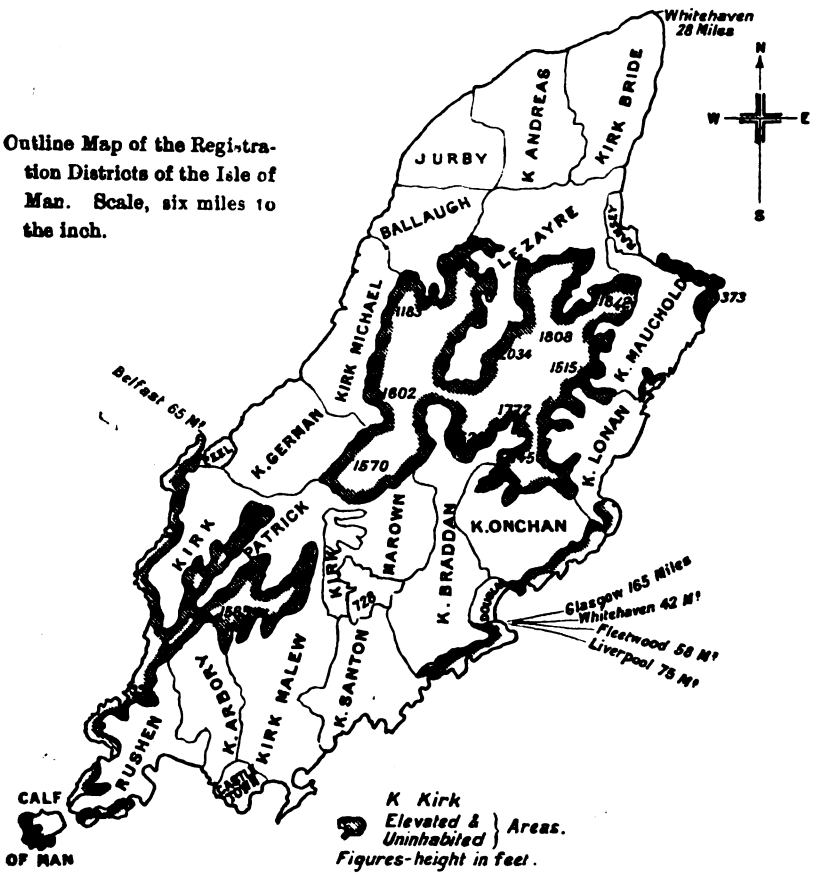
The subject I have selected for my address is one that requires no apology on my part for its introduction, as ever since I first landed in the Isle of Man, in August, 1882, I have been identified in the minds of at least your senior members with the study of geography—a study that I have persistently pursued more or less throughout my professional career, and which since 1868 has assumed the more definite form of the medical geography of Great Britain. With these few remarks I will now trace the course of my studies in the Isle of Man back to their origin in the greater island of Britain, which I was on the point of calling the mother-country—a term of endearment, however, not warranted by the Keltic origin of Manxmen. In 1875 I first published my folio work on "The Geographical Distribution of Heart Disease and Dropsy, Cancer in Females, and Phthisis in Females," illustrated by the coloured maps I here show, which I will presently briefly explain. In these maps you will observe that the Isle of Man is left uncoloured—blank, in fact. Now, it so happened that in 1882 I visited Brighton and made a thorough investigation of its physical configuration and geology, the results of which I embodied in a large map published by Bacon and Co. When Brighton was drained the engineer fortunately was an accomplished geologist and made coloured drawings of the sections cut for the sewers; these were placed at my disposal by the mayor and corporation of the borough. With these materials I was enabled to construct the map before you, which, I am pleased to know, the sanitary authority and others still find useful. Some years previously (1875) I had read a paper at Brighton showing the distribution of deaths among children from tuberculous deposits in the membranes of the brain and the mesenteric glands, and pointed out the high mortality from these causes that characterised the coastal districts of England and Wales. My geological map of Brighton, which included a portion of Hove, dispelled the illusion that this town was "all chalk, all chalk," as it had been described by some London medical men who were in the habit of sending their patients there with the view of counteracting the evils arising from London clay. From Brighton I proceeded to Scarborough, when I completed my investigations with regard to the low death-rate from phthisis there, to which I shall again refer when speaking of that disease in your island. Whilst, however, I was staying at the Yorkshire health resort my attention was again drawn to the blank area in my map lying in the Irish Sea, midway, as Cæsar described it, between Britain and Ireland, and nearly through the centre of which passed the same line of north latitude, 54° 5′, that traversed Oliver's Mount, which rises over 500 ft. above the sea in the centre of Scarborough. Having determined to extend my inquiry to the Isle of Man I wrote to the then Registrar-General, Mr. Samuel Harris, now the Vicar-General, who immediately forwarded to me copies of his two first-printed annual reports for the years 1880 and 1881, being his fourth and fifth respectively; his former reports for the years 1877, 1878, and 1879 had not been printed and published and are still in MS. Since the year 1880 up to the present sixteen printed annual reports have been published, and presently I shall endeavour to lay before you some of the facts accumulated during the decennial period 1881–90, and compare them with those published by Dr. John Tatham in August last in his admirable supplement to the fifty-fifth annual report of the Registrar-General of births, deaths, and marriages in England, which embraces the same period.

The scanty materials afforded by the two printed annual reports of the Manx Registrar-General were to a certain extent disappointing, but I was not disheartened, and having just concluded an eight years' campaign against disease in the midland counties, over an area of more than a thousand square miles, containing nearly four hundred parishes (365), I lost no time in commencing my investigations on the same lines that I had laid down for my guidance whilst carrying out the larger work. The first thing to be done was to gain an accurate knowledge of the physical configuration and geology of the Isle of Man. These ends I attained, as well as I could, by walking all over the island and sketching its mountains, its valleys, its cliffs—in fact, everything that would give me a clue to solving the problems of its local climates and their relation to health and disease. This part of my work would take up too much wall space to exhibit here, but a few of my sketches that I once reduced and which were engraved for publication, now abandoned, are on the table, and may help to show you the nature of this part of the investigation. The study of the geology of the island went side by side with that of its physical geography, and as the mildness of the Manx winter enabled me to pursue my studies almost uninterruptedly I soon acquired a sufficient knowledge of every part of this beautiful rock in the Irish sea called *Mona* by Cæsar, and *Man* by us, from the old Keltic word *Maen* a rock. My next step was to make special inquiry as to the prevalence or otherwise of certain causes of death in the different parishes, carrying out a thorough house-to-house visitation, for which I had provided myself with lists of the names of those who had died from any one of the specified diseases. In this way I made use of what I have characterised as "scanty" data, but their teaching when studied with their surroundings proved in the sequel to be of great service, and I have long since ceased to regret the extra labour that they cost me.

It was during this house-to-house visitation that I learned the true state of old Douglas, and was enabled to advise those in authority against enwalling it, as was once proposed, but to air-flush it by means of new wide streets and the destruction of the old and narrow ones—which piece of advice I have remained here long enough to see carried out to a salutary extent. You still want baths and wash-houses, and the clothes dried before being taken home to the artizans' and labourers' dwellings.

Before entering upon the description of the maps of disease-distribution in the Isle of Man I must very briefly explain the maps that I had previously constructed to illustrate the medical geography of heart disease and phthisis and cancer in England and Wales; the heart disease map was first published in 1871, then again in 1875, with those of the two other diseases. In 1892 I published, as an introduction to the Medical Geography of Great Britain,[2] the first part of the second edition of that work, and illustrated my method of investigation by maps of the Geology, Physical Geography, and Disease Distribution in the English Lake District, so that I need not now enter further into detail than will be sufficient to enable you to read my English maps and compare them with those I have constructed for your country. Moreover, only so lately as last May Professor Thomas Clifford Allbutt published in his "System of Medicine"[3] an article on the "Medical Geography of Great Britain," which he had asked me to contribute to his great standard work. In this contribution I endeavoured as succinctly as possible to explain the principles of this important branch of knowledge and their application to clinical medicine. To these works, therefore, I must refer the members of this society who desire to become further acquainted with the history and results of my investigations.

On the three maps of England and Wales before you are portrayed, by means of different shades of red and blue colours, the distribution of three great causes of death—heart-disease among males and females, phthisis among females, and cancer among females—



[1] Mr. Haviland's address was freely illustrated by coloured maps and diagrams.

during the decennial period 1851-60, the data for which were received from Dr. William Farr's first supplement to the Registrar-General's twenty-fifth annual report. The scale of colours is the same in all the maps, whilst the death-rates, of course, differ according to the cause of death represented. I selected red and blue with the view of aiding the medical memory, the first being typical of red, life-giving arterial blood, the symbol of health and low mortality as indicated by death-rates below the average, whilst the second represents the colour of effete and used-up venous blood, the emblem of disease and high death-rates, or a mortality above the average. The lowest mortality is indicated by the darkest red and the highest by the darkest blue, the intermediate shades between these polar extremes gradually decreasing in intensity as they approach the central average point, which in the case of heart disease (for both sexes) was during 1851-60 equal to an annual death-rate of 12·45 to every 10 000 living, in that of cancer of 4·33, and of phthisis of 27·74 to every 10,000 females living. The number of deaths from heart disease during the above ten years amounted to 236,973, from cancer 42,137, and phthisis

Outline Map of the Registration Districts of the Isle of Man. Scale, six miles to the inch.

have hitherto dealt. It is true that on comparing this map with that of phthisis, the two when placed side by side present a marked contrast to one another; but this is more due to the fact that cancer affects the river-valley systems, which when protected and sheltered harbour the *materies morbi* of rheumatism, and its too frequent sequel heart disease, than to a common cause. A few illustrations, however, will suffice to show the nature of the problems that this remarkable contrast affords us. I will follow the plan I have hitherto adopted and begin with the high mortality groups; these will be seen to skirt the lower courses of fully-formed rivers that seasonally flood their riparial districts, instances of which will be seen, especially on the east and south coasts, from the Tweed to the Devonshire rivers, between which extremes will stand out the blue colouring of high mortality along the Rivers Tyne, Swale, Humber, Welland, Trent, Ouse, Yare, the East Anglian rivers, Thames, and the south coast rivers. The Thames Basin has long been known as one of the great cancer fields of England and Wales, and I may say, in passing, that with the fresh light thrown on this subject by the increased numbers afforded by the deaths occurring during 1881-90 the mortality tends to show an increase instead of a decrease. This highly important area has been treated separately and the history of cancer within it will be shortly published. It is natural to suppose that if floods tend to increase the mortality from malignant diseases in the districts where they occur, the localities where floods do not and cannot occur should be comparatively free from these diseases; or that if the low-lying clays and retentive soils which characterise the high-mortality flooded areas are replaced by elevated permeable formation, such as the several limestones, then, too, the death-rates would lessen and the groups would be characterised by shades of red, such as can be seen throughout the palæozoic and elevated areas of Wales, the north-west of England, the chalk downs on the north and south of the Thames Basin — in fact, wherever chalk and other limestones come to the surface. Having given you a hasty sketch of the teachings of these three maps I will now pass on to the geographical distribution of the same causes of death in the Isle of Man during the ten years 1881-1890. The groups of high and low mortality are represented by the same scale of colours, but the scale of mortality will be adjusted according to the insular averages.

The Isle of Man is divided into twenty-one districts, seventeen parishes, and four townships for registration purposes (see Map). These are classed together into four divisions, consisting of the Western—Peel, German, Patrick, Michael, and Ballaugh; the Northern — Ramsey, Maughold, Lezayre, Andreas, Bride, and Jurby; the Eastern—Douglas, Onchan, Lonan, Braddan, and Marown; and the Southern—Castletown, Malew, Santen, Arbory, and Rushen. The Act of Tynwald, by which the registration of births, deaths, and marriages became law, was promulgated on July 5th, 1878, so that it was in force for a year and a half before the Registrar-General's report for 1880 was printed. In 1881 the next census after that year took place, and in 1891 the ten years were again completed by the census of that year, and thus enabled the mean populations of the several districts to be taken for the ten years 1881-90 by adding the two censuses together and dividing by two, as in the cases of the English and Scotch censuses. Although I have worked out in a tabular form all the details of the twenty-one districts for each of the single years composing the decennium 1881-90, as regards their mean populations, numbers of deaths from each of the three causes for each year, and the annual death-rates from them, I shall content myself on this occasion with only

269,618 amongst a mean population in the first instance of 18,996,616, and among the two latter of 9,718,174 females.

With this brief preliminary explanation I will now endeavour to show you what the three maps teach us, and then proceed to compare the lessons derived from them with those afforded by maps of the Isle of Man, representing the distribution of deaths from different causes over an equal number of years, although not for the same decennium. The English maps are divided into 630 registration districts.

[Mr. Haviland here described the three maps of England and Wales, relating to A, Heart Disease in both Sexes; B, Phthisis in Females; and C, Cancer in Females. In Map A mortality was least in wind-swept districts where the valleys lay in the axes of the prevailing winds. In Map B the opposite state of things prevailed, and as regards Map C Mr. Haviland continued:—]

The cancer map.—I now proceed to explain the groups of high and low mortality among females from cancer. The causes regulating the distribution of death from malignant diseases will be seen to differ widely from those with which we

Digitized by Google

laying before you a summary of the results of my investigation, reserving for your future reference the tables containing the actual figures, as they will be of more use in the study than in the lecture room. Ever since the first publication of my English maps, the first thing that appears to strike the student is the fact that the truthful delineation of the distribution of a cause of death, carefully worked out by death-rates from it, should give a clue to the physical geography and geology of a country. That such, however, is the case no one, I think, will now deny who has attentively followed the explanations I have given of the groups of high and low mortality from the three classes of disease that have just been discussed. England and Wales offer every variety of physical and geological feature, from the elevated mountain masses of the Cambrian and Lake District, the Snowdon, and great water parting of Wales, and the Derbyshire and Devonshire peaks and moors in the west, to the rich central valleys of the Severn, the Thames, and the broad stretches of flat, alluvial lands in the east; and when we consider that this diversity of land surface is spread over an area of nearly 60,000 square miles (58 186), we may well hesitate to accept the teachings of a little outlying island only 227 square miles in extent with those of a country more than 256 times as large. "*De minimis non curat lex.*" But science does, fortunately, and, moreover, science from day to day accumulates the facts on which it is built, and, like a rolling snow-mass, *vires acquirit eundo*, so we will make a beginning with the first few possible facts that have come to our hand since your Registration of Deaths Act was first promulgated from your ancient Norse Tynwald Hill on July 5th, 1878. Let us, then, begin with a brief enumeration of the main facts at our disposal. The area of England and Wales, I will remind you, is equal to 58 186 square miles, and is divided into 631 registration districts, giving an average area to each of 92 square miles, whilst that of the Isle of Man is 227 square miles, divided amongst 21 districts, giving an average of a little over 12 square miles each. The four town districts are the smallest but most populous, as in England, and it will be seen by the map before you showing the elevated land that large areas of several of the rural districts in the north-east and south-west of the island are occupied by sparsely-inhabited mountain lands. These culminate in the north at Snaefell, 2034 feet, and in the south at Barrule at 1585 feet. Running, as these masses do continuously from the north-east in the Maughold district to the south-west in that of Rushen, they form the backbone of the island, and roughly separate the north-west from the south-east aspects.

Heart disease.—The number of deaths registered as caused by diseases of the circulatory organs amounted "at all ages" to 402 males and 499 females during the decennium 1881–1890 in the Isle of Man amongst a mean population of 26 044 males and 28,538 females, equal to an annual death-rate of 15·43 among males to every 10,000 males living, and of 17·48 among females. During the same period the death-rates in England and Wales were 15·47 and 16 02 respectively, so that the death-rates are very similar to those of the island, being only 0·04 less among males and 1·46 more among females. On looking at a map of the Isle of Man there will be little difficulty in pointing to the districts that are liable to the full force of the prevailing winds which we have seen in England to have such a powerful effect in reducing the mortality from diseases of the circulatory organs. The axis of the island corresponds with the line of the south-west and north-east prevailing winds. The southern division embraces the wind-swept parishes of Rushen, Arbory, and Malew, the death-rate amounting to only 7 19 males and 11·34 females to every 10,000; whilst the more sheltered parishes, as Michael, under the lee of the precipitous cliffs, have a much higher death-rate, 17·64 males and 18 41 females; Marown, 22 82 females. Among males, however, the death-rate is low, 8 11. I have omitted the results from the towns and from Braddan, as they contain the lunatic asylum and the poor-house, the deaths in which have not been accounted for. Santon, too, contains the isolation hospital, in which several deaths have taken place. Corrections for deaths in these institutions should in future be made.

Phthisis.—In the ten years from this cause there were 722 deaths among males and 815 among females, equal to a death-rate of 27·72 among the former and 28 55 among the latter. In the first map that I constructed for 1880–1882 the distribution of phthisis among females in this island was faithfully foreshadowed, and will help us to understand the figures of the ten years 1880–91: Bride, 46 51; and Ballaugh, 32·25, in the north; and Rushen, 31·10, and Arbory, 37 69, in the south. On the west coast, under the shelter of the Kirkmichael cliffs, there was a low mortality (20·25), as was found under the protection of the Scarborough and the North Devon cliffs. In fact, as I pointed out in Edinburgh when I lectured before the Scottish Meteorological Society on the Climate and Diseases in the Isle of Man as Influenced by Physical Configuration, although in some of the wind-swept parishes a very high death-rate from phthisis occurs, there are to be found in the centres of the mountain masses ample valley room for the erection of cottages where protection would be afforded, not only to the inhabitants of the island, but to the lung-tainted visitor, who would find the purest elevated climate conceivable and protection from wind. At that meeting I proposed, instead of building hospitals for phthisical patients, that cottages so constructed should be built as to turn round on a table and be adjusted so as to meet the varying sun and wind changes.

Cancer.—130 males and 195 females died from this cause during 1880–91, thus yielding an annual death-rate equal to 4 99 and 6·83 respectively. During the same period the death-rate in England and Wales reached 4 30 males and 7 38 females. In England phthisis had decreased greatly since 1851–60, when it amounted to 27·74 amongst females; in 1881-90 among that sex it had fallen to 16 08. In the Isle of Man there are no extensive river basins subject to floods, but there is elevated ground and a central valley which receives the drainage of the northern and southern masses. This valley stretches between Douglas and Peel and traverses the central parish of Marown. Its area is nearly always water-logged, and this condition of the soil I have always associated with the prevalence of cancer. Coincident with the Marown swamp is the highest death-rate from cancer among females—namely, 16·59; the next highest is found in Andreas (8 51), in Michael (7 36), and in Arbory (8·56), all more or less subject to water-logged soil. The elevated localities, such as Maughold (1·95), Lonan (5·89), and some others, as Malew, characterised by a large area of limestone (5·23), Santon (3·71), and Patrick (2·54) have all the lowest death-rates from malignant disease.

I have now given you a hasty sketch of the distribution of certain important causes of death in the Isle of Man during the ten years 1881–90, the details of which are to be found for every parish. This essay must be considered as a starting point only. This is the first attempt that has ever been made to apply the principles of medical geography to your island excepting the one that I published in 1883 on the distribution of phthisis in it. I must now leave this subject in the hands of the members of this society, who, I hope, will pursue it year after year as the disease facts accumulate. And in expressing this hope I will, in conclusion, add a word of encouragement: In the study of medical geography the busy medical practitioner will often find the material for answering such important questions as "where shall I go to avoid the chances of falling a victim to the disease with which I am tainted?" With such evidence before you as the maps present no medical man would recommend a patient to take up his abode where he knows the local climate is favourable to the diseases for which he is consulted. Fortunately for those visiting the Isle of Man, the local climates are so pronounced and varied, owing to the great diversity in its physical configuration, that when once mastered and the distribution of disease well studied, no difficulty will be experienced in answering such questions. Again, during convalescence—a period in our patients' cases of great anxiety to us, as it is one of great susceptibility to morbid influences—medical geography will often point out to us the places to be avoided when the time for a change of air arrives, as well as where are to be found the most suitable local climates.

A DANGEROUS ATTACK BY A LUNATIC.—We regret to learn that on July 17th, whilst on the cricket field, Dr. Merson, medical superintendent of the Hull Borough Asylum, received a violent blow on the back of the head from one of the patients, the blow being struck with a cricket bat. Dr. Merson was rendered unconscious immediately and remained so for several hours. His condition caused great anxiety for some days, but we are pleased to learn that he is now progressing favourably, though slowly.

A CONTRIBUTION TO THE ETIOLOGY OF BERI-BERI.[1]

BY WALTER K. HUNTER, M.D., B.SC. GLASG.,
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, AND TO THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

THAT the symptoms and signs of beri-beri are due to a multiple peripheral neuritis is, I think, now an accepted fact. The question which remains at issue, if, indeed, it has not yet been settled, is, What is the cause of this neuritis? A multiple neuritis is symmetrical, and, being so, the parenchymatous degeneration of the affected nerves must be due to some irritant circulating in the blood, this irritant having a special affinity for the nerve protoplasm. The peripheral parts of the nerves are the parts most affected, because, these being farthest from their source of nourishment, their vitality will be proportionately less, and they will therefore the more readily undergo degeneration.[2] We are familiar with many examples of multiple neuritis caused by poisons circulating in the blood. Alcoholic neuritis, arsenical neuritis, the neuritis of small-pox, of enteric fever, and certain aspects of diphtheritic paralysis, may all be cited by way of illustration. In the first two cases, alcoholic and arsenical neuritis, the poisons get into the circulation from without by means of the digestive system. In the other cases, or at least I may say without fear of contradiction in the cases of diphtheria and enteric fever, the toxins are manufactured in the blood or tissues, the result of the vital activity of certain specific micro-organisms.

Early in the study of beri-beri it was recognised that its symptoms must be due to some deleterious, if not actually poisonous, substance present in the circulation. With this in view many and various causes were mentioned by way of explaining the etiology of the disease. It was thought to be allied to rheumatism, to scurvy, to be a form of malaria. Wernich examined the blood in many of his patients, and he concluded that the disease was similar to pernicious anæmia. This theory, he maintained, would explain the cardiac failure, the dropsy, and the nervous and other symptoms. But it was found that the changes he described in the blood were by no means common to all cases of beri-beri, and that, indeed, many of these changes did not exist in reality, but only in his preparations, the result of his faulty methods of examination. Diet, again, was claimed to be the cause. It was said that many of the sufferers lived entirely on rice, and that on substituting a more nitrogenous food they showed marked signs of improvement. Others maintained that the diet was too rich in nitrogenous material and claimed an improvement on giving less. Impure water, overcrowding, gases from organic decomposition, were all given an important place among the causal factors of the disease. But a more adequate explanation than any of these had to be found, for not one of them was convincing or satisfactory. In some of the other infective diseases a micro-organism had been found in the blood or tissues of those affected. These organisms in growing produced certain poisons called toxins, and it had been shown that the poisons so produced were the causes of the characteristic symptoms of the disease. The task, therefore, which presented itself was to find in the blood or tissues of people suffering from beri-beri a specific micro-organism with characters analogous to the organisms of such diseases as diphtheria or enteric fever. Some idea of this kind was evidently in Simmons's[3] mind twelve years ago when he wrote as follows: "Ten years' study and observation of the malady (beri-beri) under a great variety of circumstances and conditions have led me to the definite conclusion that its exciting cause is a specific poison or germ, having many striking resemblances in its mode of production to paludal or marsh miasm, though entirely distinct and separate from it."

Various investigators have discovered micro-organisms in the blood and tissues of patients suffering from beri-beri, but unfortunately the variety of these organisms is very considerable. Pereira[4] in 1874 reported the presence in the blood of micro-organisms, which he described as "micrococci in rapid motion." He says he also found these in normal blood, and so he considered them as of no importance. It is therefore probably De Lacerda[5] who deserves the credit of being the first to describe an organism which he considered to be the cause of beri-beri. This was a bacillus, the same, he says, as he cultivated from rice, and the same as he found in the blood of rats that had died after eating the rice. Some years later, however, in 1887, De Lacerda[6] cultivated cocci from the blood of his beri-beri patients and by inoculating rabbits with the growth produced the symptoms of that disease. In 1885 Ogata[7] found in the spinal cord of a patient who had died from beri-beri a bacillus something like the anthrax bacillus. Growing in gelatin it had a "tree-like" appearance, and on agar-agar a "yellow-grey-white" colour. On injecting cultures of this bacillus into mice and dogs, he says, there was developed in them the symptoms of beri-beri. He cultivated the organism on a medium of gelatin and grape sugar, and found that the fluid resulting from this growth on being injected into animals caused paralysis. He found his bacillus in the intestines of those suffering from beri-beri, and concluded that it was the toxins of these bacilli being absorbed into the circulation that caused the paralytic symptoms. In 1887 Van Eecke[8] reported that he had cultivated four different kinds of organisms from the blood of his patients. These were as follows: (1) "Micrococcus albus," a micrococcus which was immobile, aerobic, and which liquefied gelatin; (2) "micrococcus tetragonus flavus," cocci arranged in tetrad forms; (3) "micrococcus flavus," also aerobic and liquefying gelatin; and (4) "bacillus flavus," short rods in pairs and chains, in active motion, aerobic, and with spore formation. On injecting animals with these growths, three of them, the first, third, and fourth, each produced paralysis. No result was obtained with "micrococcus tetragonus flavus."

However important all the above observations might be, it was not till Pekelharing and Winkler[9] took the subject in hand that anything like a satisfactory account of the bacteriology of beri-beri was given. These investigators in the first place sought for an organism in the tissues and cerebro-spinal fluid at their various post-mortem examinations, but with no conclusive result. On examining, however, the blood of the patients while alive the result was much more satisfactory. In the blood were found numerous micro-organisms, both cocci and rods, and these were demonstrated in unstained as well as in stained specimens. An extended inquiry as to the condition of the blood in people residing at Atjeh and at Batavia was next undertaken. In the former place, where beri-beri is very prevalent, most of the inhabitants had "cocci and bacteria" in their blood, whether they were actually suffering from the disease or not. At Batavia, on the other hand, where beri-beri is almost never met with, the blood of its residents showed total absence of these organisms. As regards the micro-organisms in the blood of the so-called healthy people in Atjeh it was pointed out that almost no one enjoyed good health there. Most of its inhabitants complained of a feeling of heaviness, lassitude, palpitation, pains, and often loss of tactile sensation in the legs. The medical men who were carrying on the investigation also experienced these symptoms, and they were not free from them till they removed to Batavia. Fresh arrivals at Atjeh had no micro-organisms in the circulation, but these could almost always be demonstrated after a short residence, disappearing, however, on removal from the infected neighbourhood. All these observations gave confirmation to the surmise that beri-beri was due to the micro-organisms in the blood. The next step was to cultivate the organism or organisms outside of the body. This was found to be a matter of considerable difficulty. Cultures were taken from the blood of eighty patients, in all of whom micro-organisms had been demonstrated to be present. Of the eighty tubes only fifteen showed any growths, and not all of these growths were alike. Of the fifteen, twelve were micrococci and three were rods. Of the twelve micrococci, nine seemed alike, and these showed a close

resemblance in many of their characters to staphylococcus pyogenes albus. Two more of the tubes contained yellow growths; the twelfth was not well made out. The growths in the three tubes with rod-shaped organisms differed considerably from each other. It is to be noted that of the nine white micrococci six liquefied gelatin and two did not; the ninth was lost. In addition to cultivating these micrococci from the blood, Pekelharing and Winkler had no difficulty in growing a similar organism from the air of houses in Atjeh. It was now necessary to test the pathogenic characters of these micro-organisms. Single injections of cultures, it was found, produced no effects on animals; but this was quite to be expected, for the disease beri-beri differs from other infective diseases in that, while most of the others require but one exposure to their infecting agent, it is necessary to have a prolonged contact with the virus of beri-beri to ensure the development of that disease. And so the injections were given at intervals, and were continued over periods extending from nine to forty-eight days. Seven rabbits and two dogs were treated in this way with cultures of the white micrococcus. Six out of the seven rabbits and one of the dogs showed on post-mortem examination well-marked degeneration of their nerves. From the blood of these animals the same micrococcus was cultivated, and this in its turn produced a nerve degeneration in other rabbits. Cultures of the white micrococcus were given to rabbits along with their food and diffused in the air they breathed, with results similar to those obtained on injecting this virus. Again, saline solutions impregnated with the air of a room in Atjeh were injected into a rabbit. This animal died, and the post-mortem examination showed a degeneration of its nerves. Micrococci, too, were cultivated from this rabbit's blood, and these produced degeneration of nerves in other animals. Control observations were made, the control animals being kept under circumstances exactly similar to the ones receiving the injections. No nerve degeneration was found in the former. A rabbit was injected with a culture of staphylococcus pyogenes albus. The rabbit died in five days, and abscesses were found in its liver and kidneys, but no degeneration in its nerves. The pathogenic properties of the three rod forms and of the two yellow cocci cultures obtained from the blood were in a similar way investigated, but there was no certain evidence to show that any of these caused a nerve degeneration. The conclusion, therefore, that Pekelharing and Winkler arrived at was that the "white micrococcus" they cultivated from the blood is the cause of beri-beri. As to its liquefying gelatin or not, that they thought to be a matter of no moment, but to depend mostly on the culture medium on which the organism was grown. The "rod forms" were supposed to be extraneous, probably impurities. The "yellow cocci" they seem to think in some way related to the "white cocci," but on this point they are not very clear. They believe that the "white cocci" impregnate the air of the infected houses, ships, and districts, get into the human circulation through the air passages, and when they are absorbed in sufficient amount—some weeks' exposure to the infection being necessary—produce in the blood toxins in such quantity and of such a nature as to bring about a parenchymatous degeneration of the peripheral nerves.

Following on these observations of Pekelharing and Winkler came Eykmann[10] (1888), but he could not confirm their conclusions. He himself got only negative results from the study of the bacteriology of beri-beri. Neither could Mendes[11] agree as to the specific nature of the cocci of Pekelharing and Winkler. In 1887 Sternberg,[12] when in Rio de Janeiro, tried to cultivate an organism from the blood of four typical cases of beri-beri, but his results were also quite negative. Leopold[13] in 1892 isolated four micro-organisms from the blood of his patients. These were as follows: (1) "staphylococcus pyogenes albus"; (2) "micrococci in chains"; (3) "a small streptococcus, colourless, of unknown character and difficult cultivation"; and (4) a micrococcus which by inoculation in guinea-pigs and dogs causes a degenerative neuritis, and is described as the micrococcus of beri-beri. In 1893 Musso and Morelli[14] cultivated from the blood and ascitic fluid of two cases of beri-beri a micrococcus which, when injected into rabbits, produced symptoms of beri-beri. Scheube, in his "Die Beriberi-Krankheit," (1894), while recognising the importance of the observations of Pekelharing and Winkler, takes great exception to many of them. He maintains that they did not produce beri-beri in the animals they injected and that the cocci found by them are not the cause and not even one of the causes of the disease. If the organisms are present in the blood, why in sixty-five out of eighty cultures were no growths obtained? He says their results do not confirm each other and that some of them do not seem trustworthy. He does not think it probable that beri-beri can be produced by several organisms, as was suggested by Pekelharing and Winkler, and, again, he thinks they treat the bacilli and yellow cocci they cultivated too lightly. He wants to know how these could get into the test-tubes if not from the blood. He points out that some of the cocci liquefied gelatin and that some did not, the former seeming the more virulent. He asks why no result was obtained by giving injections from the blood of those affected with beri-beri. He maintains that the cause of beri-beri has not yet been discovered. Lastly, Fiebig[15] argues that the micrococcus cultivated by Pekelharing and Winkler is the same organism as staphylococcus pyogenes albus. He says the two have many resemblances and that they have no differences which could not be explained by alterations produced on growing them on different culture media.

From this account of the observations made and the opinions held as to the etiology of beri-beri it will readily be seen that all are not agreed as to the nature of its specific micro-organism. And in this connexion I may quote Dr. Spencer,[16] who, no later than seven months ago, wrote as follows: "In spite of the arduous researches of Pekelharing, Winkler, and others the organism which is the cause of beri-beri has not been satisfactorily or certainly determined." At this stage of the discussion, therefore, all fresh observations cannot but be received as evidence of some value. And so, I think, I need urge no excuse for presenting the results of a bacteriological examination of the blood in even only two cases of beri-beri.

Two firemen from the s.s. *Britannia*—(1) a man aged twenty-five years, and (2) a man aged twenty-three years—were admitted into No. 11 ward of the Glasgow Royal Infirmary on Feb. 26th, 1896. Their last port had been Bluefields, Nicaragua, and as far as could be made out they were two of seven lascars on the *Britannia* all affected with the same symptoms, and presumably the same disease, but not at the same time. Three of the seven had been sent to hospital in America, other two died on board the ship, and the remaining two, the patients under notice, arrived in Glasgow. When admitted into the ward each gave almost exactly the same clinical history and both showed very much the same physical signs. The symptoms, they said, were of three weeks' duration and had set in with a feeling of great weakness, lassitude, and loss of power in the legs. The gait of the patients was unsteady, especially so in the case of patient No. 2, who could not walk at all without support. The knee reflexes in both patients were absent, but the plantar and abdominal reflexes were quite active. No distinct muscular atrophy could be said to be present, although there was certainly some loss of power in the arms and in the legs. The reaction of degeneration was not fully developed. Most of the muscles in the limbs showed much lessened excitability to Faradaic electricity, yet some response was almost always obtained with a sufficiently strong current. The patients complained of pains and feelings of tingling and swelling in the feet, legs, and arms. The limbs were tender and painful to the touch, and there was a sense of constriction at the ankles, knees, and wrists, just as if a cord had been tied round these parts. Some degree of anæsthesia and analgesia was noticeable, especially in the legs. There was œdema of the legs, arms, and trunk in both the patients, but it was much more marked in the case of the second patient, who also had some cardiac complication. No murmur was to be heard over his precordial area, but the sounds were feeble, and the second sound, and sometimes the first sound, was re-duplicated. Moreover, he had signs of œdema at the base of both lungs, and possibly there was also some pleural effusion. The spleen and liver were normal in both the cases, and in both there was a trace of albumin in the urine. An examination of the blood showed

the following: patient No. 1—hæmoglobin, 68 per cent.; red corpuscles, 114 per cent.; patient No. 2—hæmoglobin, 76 per cent.; red corpuscles, 125 per cent. These two patients remained in hospital for two and a half months, and their clinical history during that time is pretty much an account of their gradual recovery. The second patient had one bad attack of syncope four days after admission, and two days after that each had a considerable rise in temperature lasting for two or three days, and for which no explanation could be found. Otherwise, the temperature was normal, the œdema gradually disappeared, the motor and sensory troubles passed off, and the patients were dismissed well.

During the residence of these patients in hospital I had the opportunity of examining their blood on four different occasions, viz.:—On March 6th and 11th, April 25th, and May 9th, and the appearances which presented themselves were the same on each occasion and in each patient. The blood was examined with the $\frac{1}{12}$th oil-immersion lens in the fresh state as well as in dried specimens stained with eosin and methyl-blue, with fuchsine and with Biondi's stain. It was noted that the red blood corpuscles ran together into rouleaux, and that the white corpuscles were slightly increased in number, many of them containing large black granules. There also seemed to be an increase in the plates of Bizzozero. In addition to the above ordinary constituents of the blood, there were present in fresh specimens small granules or micro-organisms in very active motion. These little bodies were seen as single "granules" or cocci, or as cocci in pairs (diplococci), or more rarely as several cocci joined together. Sometimes, as in the last case, they were very similar to rod-shaped organisms, but this appearance I was convinced was caused rather by two or three cocci forming a short chain than by a rod-shaped organism. That the movements observed were not a Brownian movement, but due to the organism itself, I am quite convinced, and on this point other observers who were good enough to look at my preparations were all agreed. In the stained specimens the organisms appeared almost invariably as cocci in pairs, lying over or attached to the red blood corpuscles. Never were any rod-shaped organisms seen in these preparations.

I next directed my attention to cultivating these organisms on artificial media. Tubes of agar-agar, serum-agar, and gelatin were inoculated with the blood of the patients on the following dates and with the following results:—March 7th: four tubes each of agar-agar and serum-agar and two tubes of gelatin. Growth appeared on two tubes only—one agar-agar (Growth A) and one serum-agar (Growth B)—both from the blood of patient No. 1. March 14th: four tubes each of agar-agar and serum-agar and two tubes of gelatin. The only growth here (Growth C) was in a gelatin tube taken from patient No. 2. This tube had by mistake been placed in the incubator at 37°C. April 20th: Four tubes each of agar-agar and serum-agar. Growths appeared in two agar-agar tubes (Growths D and E) and in one serum-agar tube (Growth F), all from case No. 2. April 27th: Six tubes each of agar-agar and serum-agar. Growth on one agar-agar tube (Growth G) from case No. 1. May 8th: Six tubes each of agar-agar and serum-agar and four tubes of gelatin. Growth on one agar-agar tube (Growth H) from case No. 1. From the above it will be seen that of fifty-six tubes inoculated at various times from the blood of the two patients, unequivocal growths were obtained only in eight. Of these eight tubes five were agar-agar, two serum-agar, and one gelatin (also at 37°C.). Four of the growths were from patient No. 1, and four from patient No. 2. Throughout this investigation every care was observed so that no organism from without should get into the tubes, special attention being given to the cleansing of the patient's finger from which the blood was drawn. On further investigating these eight growths it was found that only three of them (E, F, and H) were pure cultures. These three seemed to be the same organism, for their characters were exactly alike. They grew rapidly on agar-agar, there being in twenty-four hours at 37°C. an almost continuous growth along the streak. In from two to three days this had increased to an abundant pearly-white, club-shaped growth, with slightly scalloped edges, presenting an appearance almost identical with a similar growth of staphylococcus pyogenes albus. Cover-glass preparations stained with fuchsine showed the organisms to be cocci grouped so as to form staphylococci. These also stained well with Gram's method. Plate cultures were made both with agar-agar and with gelatin, and each showed the growths to be quite pure. With a low power the colonies on the agar plate were noted to consist of light-yellow or straw-coloured discs, finely granular, with well-defined edges and small, dark centre. There were also other forms to be seen, much smaller, darker in colour, round or lozenge-shaped, and in appearance rather like an uric acid crystal. These were usually separate from the larger discs, but sometimes they overlapped them, seeming to grow out of them, giving an appearance as if the darker growths were the stalk, and the lighter growths the bell, of a mushroom-shaped colony. On gelatin plates of five days' growth the colonies had much the same appearances as the above larger discs, only they seemed thicker and more granular. There were very few of the dark uric acid-looking plaques to be seen. On examining a "hanging drop" preparation cocci, solitary and in pairs, were seen to be in very active motion. The appearances here reminded one of those presented by these organisms in the fresh blood, for the kind of movement was almost exactly alike in both cases, and it certainly was not a movement in the fluid, but inherent in the cocci themselves. As to whether or not these cocci had flagella I cannot say definitely, but if they had I was quite unsuccessful in my attempts to stain them. The micrococci grow rapidly in bouillon broth, giving it in twenty-four hours a muddy appearance. The reaction of the culture-medium after a few days was strongly acid. It was demonstrated that a small amount of sulphuretted hydrogen was given off from this medium during the growth of the organisms. The addition of potassium nitrite and sulphuric acid to the bouillon growth showed the indol reaction, though faintly, yet quite distinctly. When grown on milk a coagulation is developed in from two to three days, and the fluid which separates has a strongly acid reaction and a distinctly sour smell. Stab-cultures in gelatin develop slowly and liquefaction does not seem to be constant. When it does take place it does so very slowly, sometimes along the streak, sometimes transversely at the upper part of the gelatin. Each of the three cultures we are now considering at first did liquefy gelatin, but growing them on gelatin seemed to lessen and even destroy this capacity. The growths E and F are examples of this, for now, after some eight or nine months' growth, partly on gelatin and partly on agar, I cannot get them to liquefy gelatin. At no time, even in summer, did liquefaction take place in less than a fortnight, and sometimes it did not develop till six weeks had elapsed. In the tubes where liquefaction took place the organisms, which fall to the lower level of the fluid, developed a dirty orange-coloured pigment. The fluid itself had a neutral reaction. The remaining five growths, A, B, C, D, and G, were impure, but on making plate cultures and isolating their component organisms it was found that each of the five contained a staphylococcus similar to that of E, F, and H, whose characters we have just been considering. From each there was, in addition, isolated a rod-shaped organism, but not in any two growths was this organism the same. Thus, in growth A, where both cocci and rods are to be made out in the cover-glass preparations, a staphylococcus was isolated whose appearances on plate cultures, in agar-agar tube, in bouillon broth, in its power of liquefying gelatin, &c., showed it to be the same as the growths E, F, and H. The rod-shaped organism on agar-plate cultures formed light brown or yellow colonies, quite round, granular in appearance, with fairly well-defined edges. There were also some plaques to be seen, light yellow in colour, and usually overlapping each other. The appearances on gelatin plates were very similar. On an agar-agar tube there appeared in twenty-four hours pearly-white, rounded colonies which tended to run into each other along the streak. On staining this growth it was seen to consist of short, thin rods, not stained uniformly. These stain by Gram's method, but every attempt to stain spores was unsuccessful. Hanging drop preparations showed rods in active motion. Gelatin liquefies slowly. Growth B also contained a staphylococcus of the type I have already described, except that it never liquefied gelatin. The rod organism isolated had very distinctive characters. On agar plates a colony appeared under a low power, as a more or less rounded body of amber colour, with several processes, giving in all an appearance as like as possible to that of the itch insect—acarus scabiei. After four or five days' growth on an agar tube the culture which was white began to spread out at its edges into

Digitized by Google

branches, presenting an appearance like that of a fir tree. Cover-glass preparations showed short thick rods, many of which only stained at their two ends. These rods stain well with Gram's method and show spore formation when stained for spores. A hanging drop reveals large strong rods all in active motion. Growth in gelatin stab-cultures is very slow, and when it does take place it is in the form of white fluffy discs deep down in the culture medium. There is no liquefaction of the gelatin. The next growth, C, contained a staphylococcus the same as in the other tubes. This organism grew well in gelatin, but never caused any liquefaction. The other growth isolated from tube C was a rapidly growing bacillus, which readily liquefied gelatin, and in its plate culture appearance and other characters showed itself to be bacillus mesentericus vulgatus. Growth D also contained the white staphylococcus, which in this case liquefied gelatin in three weeks. The other organism present here was a bacillus which on agar plates presented darkish-brown, hairy-looking colonies, with rather irregular outline. The agar tube taken from this in two days had a thin scum-like growth over part of its surface, and on being stained it was seen to consist of long strong rods swollen at their ends; spores were made out to be present. This bacillus was actively motile and stained by Gram's method. In the last growth we have to consider, Growth G, the staphylococcus present did not liquefy gelatin, but otherwise it corresponded in every detail to the type already so often mentioned. The rod form here consisted of short bacilli, which stained with Gram. It was a growth very difficult to cultivate, and as it died soon its characters were not completely made out.

We have now to consider the pathogenic characters of these growths from the blood of our beri-beri patients. I shall therefore proceed to give an account of the results obtained by injecting six rabbits with some of these organisms. The plan pursued in every case was to grow the micro-organism in bouillon broth for forty-eight hours, and then to inject a certain quantity of this culture, either full strength or diluted with an equal quantity of sterilised water, into the abdominal cavity of the rabbit. Special care was taken in every case to make the syringe employed aseptic and to cleanse thoroughly the skin of the rabbit before giving the injection.

Rabbit No. 1, a fairly large animal, was injected with the pure staphylococcus growth E. Eleven injections were given in twenty-six days—i.e., three injections per week. The first five injections each consisted of 3 c.c. of the broth culture, the sixth of 4 c.c., the seventh and eighth of 5 c.c., and the ninth, tenth, and eleventh each of 12 c.c. The day after the last injection the rabbit showed signs of paralysis. It could not stand, but lay on its side panting for breath. The fore legs and hind legs were extended, and it seemed quite unable to flex them. The animal was killed at once, and an examination made a few minutes later, but nothing abnormal could be made out in any of the organs. There was very slight induration at the part of the abdominal wall where the injections had been given, but no appearance of an inflammation of any of the peritoneal membranes. The liver, kidneys, and spleen seemed quite healthy. The nerves of the hind legs were kept for microscopic examination. Cultures were taken from the blood in the heart, from the spleen, and from the liver. Eighteen tubes in all were inoculated, and in exactly half of these was a growth obtained. Cover-glass preparations were made, and in all these tubes the organism present was found to be a staphylococcus. Four of these growths were now examined in detail, and they were all demonstrated to have the same characters as the coccus which had been originally injected into the rabbit.

Rabbit No. 2, a smaller animal, was injected with staphylococcus growth F. In this case six injections, each of 2·5 c.c., were given in twelve days. On the twelfth day the animal was seen to be dying, its head being much retracted and its legs fully extended. It was killed and examined at once. The appearances which now presented themselves were exactly the same as in rabbit No. 1, except that on the surface of the liver there were several small white spots about the size of half a millet seed, which were taken to be small abscesses. They contained many staphylococci. Tubes were inoculated from the abscesses and with the blood in the heart and spleen. There was a growth in the heart culture and in the abscess culture, and both of these were shown to have the character of the white staphylococcus which had been injected into the rabbit.

Rabbit No. 3, also a small animal, was injected with Growth H. Three injections of the bouillon culture, each of 6 c.c., were given in five days. About a quarter of an hour after the last injection the animal died. The post-mortem examination was quite negative, at least, as regards naked-eye appearances. There was no sign whatever of an inflammatory process in the abdominal cavity. Owing to an accident no growths could be obtained from the blood of this animal.

Rabbit No. 4 much larger than the last rabbit, was injected with the same growth (H). In this case it took six injections, each of 3 c.c., extended over twelve days, to kill the animal. Although it had seemed quite well at the last injection the rabbit was found dead the next morning. The post-mortem appearances corresponded to those of rabbit No. 2 in there being several abscesses or collections of cocci scattered over the surface of the liver. Otherwise the macroscopic examination was negative. A growth was obtained in only two of the cultures taken, and both of these were from an abscess in the liver. In this rabbit, however, only eight tubes were inoculated, and this may account for there being no cocci grown from the blood. The two growths from the liver were quite pure and contained the white staphylococcus the same as had been injected into the abdominal cavity.

Rabbit No. 5 was small, similar to Rabbit No. 2. It was injected with Growth A, which contained both staphylococci and bacilli. Seven injections, each of 2·5 c.c., were given in fourteen days. The rabbit died on the sixteenth day, with limbs extended and head retracted. The post-mortem appearances were exactly similar to those in the last rabbit, there being here also small white abscesses in the liver. White staphylococci were grown from the blood of the heart and spleen, but no bacilli were found in any of the cultures.

Rabbit No. 6 was injected with Growth G; also both cocci and bacilli. Four injections, each of 6 c.c, were given in eight days. Five hours after the last the animal died with well-marked signs of paralysis. The post-mortem examination was negative; no abscesses were present in the liver. Four tubes were inoculated, two from the blood in the heart and two from the spleen. Growth presented itself in three of these. Two were pure staphylococci, but the third, in addition to the same staphylococcus, contained a rod-shaped organism. This bacillus, however, on plate cultures and otherwise, showed itself to be quite a different organism from that contained in Growth G, and so I take it to be an impurity and to have no relation to the subject in hand.

Nerves from the hind legs of these six rabbits were removed, stained, and examined microscopically. In doing this great care was taken so as in no way to stretch or otherwise bring about an artificial appearance in any of the nerve fibres. The nerves were fixed and stained at the same time in osmic acid (1 per cent.), and most of them counter-stained with alum carmine. Portions of the nerves were then cleared in a mixture of aniline oil and xylol, and then in xylol alone, and while in the latter the individual nerve fibres were as much as possible separated the one from the other. The specimens were mounted in Canada balsam. To make sure that this process had nothing to do with the altered appearances in these nerves I prepared in exactly the same manner nerves from a healthy rabbit, and these latter I found to remain perfectly normal. A careful microscopic examination of the nerves from the six rabbits readily convinces one that a parenchymatous degeneration is present in every case. This certainly is much more marked with some than with others—for example, in rabbits No. 2, No. 3, No. 5, and No. 6 the degeneration is so complete that there is difficulty in finding a normal nerve fibre. In rabbits No. 1 and No. 4, on the other hand, many healthy fibres are to be seen. In the degenerated fibres the myelin is sometimes seen as a series of frothy-looking masses filling up the sheath, and giving a segmented appearance to the fibre. Sometimes the myelin is in the form of small rounded balls stained black or brown in the centre of the sheath. Sometimes, again, the sheath seems empty except for its nuclei, which in some of the specimens are much increased in number. Some of the nerve-fibres have a spindle shape, one part of the sheath being filled and swollen up with frothy myelin, while an adjoining portion has its walls in close apposition, the myelin at this part having disappeared.

The importance of micro-organisms as factors in the causation of disease is now well recognised. But the discovery of "specific microbes" has so often been claimed, and these

Digitized by Google

claims have so often proved unfounded, that the scientific world is very slow to recognise any such discovery without its being backed by the strongest proof. The conditions which are now considered necessary to prove a certain organism the cause of disease have been laid down by Koch.[17] They are as follows: (1) The micro-organism must be found in the blood, tissues, or secretions of the animal affected with, or dead the result of, the disease; (2) this organism must next be cultivated on media outside the body, and this for several generations of the organism; (3) this culture in turn must be shown to produce on inoculation the same disease in a healthy animal; and (4) in this animal the same micro-organism must again be found. To these four conditions have been added[18] (5) that the same micro-organism must be found in all cases of the particular disease under consideration; and (6) that this organism must never be found in any other disease. The first four conditions were certainly fulfilled by Pekelharing and Winkler before they claimed their white staphylococcus to be the specific micro-organism in beri-beri. And in view of all the criticism their observations and conclusions evoked, it is a great satisfaction to me to find that my results, be they only from two cases, correspond to, and, if I may say, corroborate in almost every detail, the work of these two men. I found a micrococcus to exist in the blood of the two patients on every examination. A micrococcus was demonstrated to be present in all the cultures obtained from this blood. The injection of these cultures into rabbits was followed by signs of paralysis, and at the post-mortem examinations peripheral neuritis—the characteristic lesion of beri-beri—was a constant appearance. Lastly, the same micrococcus was found in the blood or tissues of the rabbits so treated. So that I, too, have fulfilled Koch's four postulates, and therefore my conclusion also must be that this white staphylococcus is the cause of beri-beri.

On considering again for a moment the opinions of the former writers on this subject we find that the great majority of them also seem to be in favour of the micro-organism being a white staphylococcus. Pereira found micrococci in active motion in the blood, and the reason doubtless that he failed to obtain results by injections with these micro-organisms is that he did not understand that not one only, but many injections are required to develop the disease. His observation as to the presence of these micrococci in 2½ per cent. of healthy people corresponds in a measure to that of Pekelharing and Winkler, who, as we have seen, explain that in an infected district the so-called healthy are seldom really healthy, but suffer in some degree from the presence of the micrococci in their circulation. The later observations, too, of De Lacerda, the conclusions of Van Eecke, of Leopold, of Musso and Morelli, all are in favour of a micrococcus. It is true that much from these last cannot be taken as sound evidence, for they do not seem in many cases to have fulfilled Koch's "laws" before drawing their conclusions. Yet be its value what it may, this evidence is in favour, and certainly not against, a micrococcus being the specific cause of beri-beri. Ogata, on the other hand, claimed a bacillus to be the organism. This, however, as far as I can make out, was never cultivated from the blood of his patients, but from the alimentary tract, and after death from the fluid or tissues of the body. Now, one understands that it would not be difficult to cultivate from a dead body, and this especially in a warm climate, an organism whose toxins injected into a mouse would cause the "symptoms of beri-beri." And may not the same be said of a culture taken from the alimentary tract, especially in patients not in good health? I think, therefore, we need give this evidence of Ogata in favour of a bacillus little consideration.

As to explaining the presence of the bacilli found by me in five cultures, and by Pekelharing and Winkler in their cultures, and so often in the fresh blood, considerable difficulty presents itself. That none of the bacilli in my five growths is likely to be the cause of beri-beri seems pretty certain. In the first place they were never seen in the blood either in fresh or in stained specimens. They are all different organisms. One of them, bacillus mesentericus, has well-known properties of its own. Two of them, each associated with the white staphylococcus, on being injected into rabbits, could not be found in their circulation, and therefore they probably did not live in the blood of the rabbits. Certainly to have completed the argument I should have tested the pathogenic characters of pure cultures of these bacilli. But as no one of them occurred twice their presence did not seem of sufficient importance to necessitate this proceeding. And here it is to be remembered that Pekelharing and Winkler proved the non-pathogenic character of the bacilli they isolated.

What, then, is the meaning of these bacilli in growths taken from the blood and how do they get there? They must either have been in the blood, on the skin of the finger, or have otherwise got into the tube from without, during the process of inoculation. If from either of the two latter sources, why have they only grown when associated with a staphylococcus, an organism almost certainly grown from the blood, and why never in any of the forty-eight tubes that remained sterile? If, again, they are from the air why only in one case was it a well-known micro-organism—bacillus mesentericus? The remaining explanation which presents itself is that the bacilli exist in the circulation as saprophytes. And in favour of this view it might be pointed out that the presence of the staphylococcus of beri-beri must lower the vitality and resisting power of the blood and tissues. In this condition, therefore, the existence and growth of saprophytes would be possible. That saprophytes, however, are not common in the blood in disease I can affirm, for during the past two years I have examined the blood, both in stained and in fresh specimens, of some eighty patients chosen from the general wards of the hospital. Only in very few cases, some pneumonias and cases of endocarditis, were micro-organisms of any kind to be found. But, on the other hand, it is well known that certain pathogenic organisms have not uncommonly present with them others which are non-pathogenic. As an example of this one may cite the frequent association in pus of the micrococci cereus albus and flavus with the streptococci and staphylococci pyogenes. But even if these bacilli in our cultures were not saprophytes, but had well-known pathogenic characters, that in no way need be an argument against our white micrococcus being the specific micro-organism of beri-beri. The presence of staphylococci and streptococci in diphtheria, associated with the bacillus of diphtheria, does not lessen the claim of that bacillus to be the specific cause of the disease, even although it has been shown that the toxins from the cocci when injected into guinea-pigs caused paralysis.[19] The important thing is that in diphtheria the bacillus of diphtheria is found constantly present, while the cocci are not; and the bacillus, too, is known to produce diphtheria whenever injected into animals. What I wish to bring out, therefore, in regard to beri-beri is that the great mass of evidence so far seems to be in favour of the micrococcus of Pekelharing and Winkler being present in all cases of beri-beri. And as this micro-organism has the property of producing when injected into animals a neuritis similar to that in beri-beri, the conclusion to be drawn is that this micrococcus is the cause of beri-beri. That the bacilli and cocci seen in the blood by the Dutch writers are, as they suggest, just two different forms of the same organism is not an explanation which commends itself to one's mind. For as far as I know there is in bacteriology no analogy for such an explanation. It is much more likely that the Dutch writers were dealing with impure growths containing both cocci and bacilli, and which, as I found, often required repeated plate cultures to be made before each could be isolated. As regards the variety of micro-organisms found in the blood by Leopold and Van Eecke, their descriptions are not sufficiently definite to let one recognise them, nor is the account of the pathogenic properties given by Van Eecke of the organism found by him at all satisfactory. Besides, most of what has already been said on the bacilli found in the blood will also apply to these other organisms. One point I wish to note here is that in my two cases the micrococci did not disappear from the blood on the patient's leaving the place of their infection. For these micro-organisms were still to be seen, and were cultivated, after two and a half months' residence in hospital and after practically all signs of the disease had disappeared.

We have now to consider Scheube's criticism of the Dutch writers, and much that he says is doubtless petty and requires no answer, but there are some points raised by him which may well demand consideration. (*a*) Scheube asks

Digitized by Google

why the micrococci of beri-beri are so difficult to cultivate from the blood, Pekelharing and Winkler only obtaining fifteen growths out of eighty inoculations, and not all of these containing cocci. I do not know that any very satisfactory answer can be given to this question, which is, I think, applicable, not only to beri-beri, but also to other diseases caused by micro-organisms, and this difficulty of cultivation from the blood is the only explanation I can give for the negative results obtained by Sternberg and other observers. (*b*) He asks why single injections with the blood of beri-beri patients do not cause the disease in animals and why repeated doses must be given so that it may develop. The reason, doubtless, is that up to a certain point the blood of the animal infected has the capacity of destroying micro-organisms either by its phagocytes or by an "antitoxin" which it seems to contain in its serum. When too many organisms get into the circulation the blood is not able to deal with them, and so they grow, producing their toxin, which, being no longer neutralised, gives rise to the symptoms of the disease. (*c*) Scheube seems to consider it impossible that the Pekelharing and Winkler staphylococcus may at one time liquefy gelatin and at another not be able to do so. But is it not the case that such a well-known micro-organism as the staphylococcus pyogenes albus sometimes shows this characteristic?[20] and the observations, extending over ten months, which I made on this point entirely confirm those of the Dutch writers. I found the liquefaction of gelatin always slow. I found that some of the growths which liquefied gelatin at first did not do so later. This, as far as I could make out, was in those organisms that had been growing for a considerable time on gelatin. Three of the growths at no time liquefied gelatin, but these were separated from impure growths, and possibly the presence of the other organism had lessened the virulence of our micrococcus. As far as I could make out, the virulence of the micrococcus was in direct proportion to its power of liquefying. For example, Growth H always liquefied gelatin, and when injected into rabbits it killed them rapidly and with small doses (Rabbits No. 3 and No. 4). Growth E, on the other hand, which had lost the power of liquefying gelatin before being injected into Rabbit No. 1, did not kill till many days later, and even then required much larger doses of the culture. Nor did the cultures grown from these and the other rabbits inoculated liquefy gelatin any more rapidly. This seems strange, for one expects the virulence of an organism to be increased on passing it through an animal that is not immune.

I have yet to refer to Fiebig's objections to the staphylococcus of Pekelharing and Winkler. He says it has the same characters as staphylococcus pyogenes albus, and he maintains that it is the same organism. It certainly has much the same morphological appearances, but the pathogenic characters of the two are very different. For would a culture of the staphylococcus pyogenes albus injected into the abdominal cavity of a rabbit produce no septic results? In not one of my six rabbits did an abscess form at the seat of inoculation, and in not one was any inflammatory condition of the peritoneum to be made out. Certainly in some of the rabbits minute abscesses were found in the liver, but these, I take it, may be looked upon as collections of cocci growing in a part of the circulation where the blood tends to stagnate. As to whether the staphylococcus pyogenes albus may under special circumstances become the staphylococcus of beri-beri or *vice versâ* I cannot say; but at present there seems to be as much difference between the two as there is between the pseudo-bacillus of diphtheria and the bacillus of diphtheria itself.

And now in conclusion it may be asked—Is it finally settled that the staphylococcus of Pekelharing and Winkler is the specific micro-organism in beri-beri? The reply is difficult. We know that medicine is not an exact science, and that its conclusions cannot therefore be drawn with the absolute certainty of a proposition in Euclid. The methods of medicine are those of observation and induction, and only when very numerous observations have been made can the conclusion be drawn with even a degree of finality. But where a finding cannot be absolute it may sometimes be comparative. When our observations are only few, then our conclusions can only be comparatively true. In medicine this latter is a position we often find ourselves occupying, and it would seem to be the one we are now standing in as regards the causation of beri-beri. A certain number of data have been furnished as to the etiology of this disease; and from these the conclusion to be drawn is, as I have contended in the foregoing arguments, that the staphylococcus of Pekelharing and Winkler is its specific micro-organism. This, doubtless, is only a "comparative" conclusion, for we have not yet data to draw one more certain.

I wish, in concluding, to express my very best thanks to Dr. G. S. Middleton, who so kindly placed at my disposal his two cases of beri-beri, with their clinical histories contained in his ward journal. I am also much indebted to Dr. Lindsay Steven, to Dr. Workman, and to Dr. Barlow for the use of their laboratories and apparatus.

Glasgow.

ON REMOVAL OF THE EYE AND MULES'S OPERATION.

BY R. BRUDENELL CARTER, F.R.C.S. ENG.,
CONSULTING OPHTHALMIC SURGEON TO ST. GEORGE'S HOSPITAL.

A RECENT number of THE LANCET contained an abstract of a paper on "Sympathetic Ophthalmitis, especially in connexion with Mules's Operation of Evisceration,[1]" which was read before the Ophthalmological Society by Mr. Richardson Cross, of Bristol, and also an abstract of the discussion which ensued. I had been forewarned of this paper and discussion, and should have been glad to hear the former and to take part in the latter, had I not been restrained from doing either by paramount considerations. I was compelled to withdraw from the Ophthalmological Society some years ago in consequence of the attitude of indulgence which it assumed towards homœopathy, an attitude which in my judgment was unworthy of honourable practitioners of legitimate medicine and surgery. I fancy that both Mr. Cross's paper and the discussion upon it must have been reported for the society by a homœopath, and that hence the valuable observations which both, no doubt, contained have been administered to your readers in a state of high dilution and mixed with an inordinate quantity of inert material. I read, for example, that Mr. Cross cited "*several* instances in which sympathetic irritation *or* ophthalmitis, had followed the operation, the proportion being as high, he said, as 13 per cent."; and, again, that he "was sure *many* cases occurred after Mules's operation even with the strictest antiseptic precautions and *often* after *many* years." The italics in both quotations are mine; and it seems almost certain that in the paper Mr. Cross must have made more precise statements than those which are attributed to him. He must surely have said how many cases of Mules's operation he had seen, how many of them had been followed by sympathetic irritation, and how many by sympathetic ophthalmitis, and exactly what he meant by "many" years in the case of a procedure which has not yet been twelve years before the profession. These and other details of equal importance will probably appear when the paper is published; but this, as I understand, will not be for some months, and then only in the Transactions of the Ophthalmological Society, a volume little likely to fall under the notice of any who are not members. The question at issue is one of very considerable importance, alike to the public and to the medical profession generally. Its discussion should not be confined within the narrow limits of a little coterie of the lovers of homœopathy, nor should any of the evidence with regard to it be consigned to a living death in the pages of their annual publication.

Dr. Mules's paper describing his operation was read in the Section of Ophthalmology and Otology at the Cardiff meeting of the British Medical Association, and was published in December, 1885.[2] Immediately after the publication I began to perform the operation, both in hospital and in private practice, in nearly every case in which I should previously have removed the eye, and I have continued to do so ever

since. I have only removed eyes (1) in cases of intraocular growth of suspected malignancy; (2) in cases in which sympathetic ophthalmitis had commenced; and (3) in a few instances of blind and painful eyes in aged people, for whom it was desirable to avoid the healing stage of a Mules's operation and with whom appearance was a secondary consideration. I retired from active duty at St. George's Hospital in 1893, so that my experience of Mules's operation extends over nearly eight years of hospital practice and over nearly twelve years of private practice. Before stating my results I would crave permission to lay down a few definitions.

In the first place, by "Mules's operation," I mean the operation as described by Dr. Mules himself and not anything else. In his own words, it is "an operation requiring care, dexterity, and careful attention to detail," and he directs the operator to take "especial care to remove the ciliary body and choroid, leaving a clean white sclera." I desire to emphasise this because in the discussion on Mr. Cross's paper Mr. Treacher Collins is reported to have asked a question on this point which was not satisfactorily answered. Moreover, an eminent surgeon once expressed to me his disapproval of Mules's operation, and rested this disapproval on a case in which he had removed the resulting stump, and had found in the scleral cavity the remains of lacerated ciliary nerves. Whatever had been done in this case was not "Mules's operation."

It seems also necessary to define "sympathetic irritation" and "sympathetic ophthalmitis." By "sympathetic irritation" I mean a state which was first described under that name, so far as my knowledge extends, by the late Professor Donders, about 1865, in one of the *Bijbladen* which it was his custom to append to the annual administrative reports of the Netherlands Ophthalmic Hospital. I have lost or mislaid the paper; but to the best of my recollection it related the case of a blacksmith, in one of whose eyes a considerable fragment of iron had lodged, destroying the sight, and occasioning, after a time, inability to use the other eye. The "irritated" eye was the subject of photophobia, lacrymation, pain, and spasmodic closure of the lids; and the patient had been unable to work for many months. The injured eye was to all appearance passive; but it was removed, together with its contained iron, and the patient was immediately and permanently cured. A few analogous cases have since been published, and in one of my own the patient, a woman, suffered, not only from eye "irritation," but also from fits resembling epilepsy. She had a violent fit when I divided her optic nerve in removing the injured eye; but it was the last, and, like Donders' blacksmith, she was cured by the operation. Cases of sympathetic irritation may be more or less severe, but their characteristic feature seems to be that the irritation has little or no tendency to pass into inflammation or to produce any structural changes in the affected eye, and that it is at once relieved by the removal of the peripheral source of the morbid reflex. I should not hesitate to endeavour to cure it by a Mules's operation, which would probably be quite as effectual as the removal of the offending eye in its entirety. I may add that, in my experience, sympathetic irritation is extremely rare; and that to hear of "several" or "many" instances of it occasions me some perplexity.

The definition of "sympathetic ophthalmitis" is more difficult, in view of the well-known fact that both eyes are liable to become diseased, one at a later period than the other, in many affections which are not commonly supposed to be "sympathetic" in that which is the last to suffer. Conjunctivitis, phlyctenulæ, iritis, ulcerative keratitis, inherited interstitial keratitis, cataract, glaucoma, and many other conditions are all prone to occur in a second eye after they have become developed in the first; and there are but few of these maladies in which the hypothesis of "sympathy" could be sustained by any evidence at present known to us. Swanzy defines sympathetic ophthalmitis as "a uveitis (irido-cyclitis, irido-choroiditis) caused by an irido-cyclitis of the other eye, the latter being usually of traumatic origin." Noyes gives nothing which can be called a definition. Klein, in Eulenburg's Real-Encyclopädie, says: "Wenn ein Auge in Folge einer spontan oder nach Verletzung entstandenen Erkrankung des anderen Auges desselben Individuums erkrankt und *nur in Folge* dessen erkrankt und nachweislich jede andere Krankheitsursache ausgeschlossen ist, so heisst die Krankheit eine *sympathische*." He continues: "Es sind mithin von diesem Begriffe alle jene Krankheitszustände ausgeschlossen, welche sich in Folge äusserer Einflüsse oder constitutioneller Körperverhältnisse des Individuums, in Folge von Allgemeinleiden oder Blutentmischungskrankheiten an beiden Augen desselben Individuums zu gleicher Zeit oder kurz oder auch längere Zeit nach einander einstellen." I conceive this to be an accurate statement of the case as far as our present knowledge extends; and I doubt whether the necessity of strictly limiting the meaning of the term "sympathetic" has always been sufficiently borne in mind by those who have written upon the subject. Of late years, for example, it has been said that inflammation and subsequent atrophy of the optic nerve may not only be a manifestation, but even the sole manifestation of "sympathetic ophthalmitis," although it is at least certain that we see such inflammation and atrophy far more frequently in cases from which the hypothesis of sympathy must be excluded than in those in which it may, even as a possibility, be admitted. It seems to be beyond the reach of doubt that certain injuries of one eye are liable to be followed by irido-cyclitis or irido-choroiditis of the other; but I am not acquainted with any other form of "secondary" eye disease in which the antecedent is sufficiently constant to be safely made the subject of a generalisation.

The difficulties hence arising are enhanced by the fact that we have no knowledge of the channels through which the forms of ophthalmitis which we most confidently regard as "sympathetic" are conveyed from one eye to the other. The ciliary nerves, the optic nerves, and the lymph channels have successively been pressed into the service; and of late years the *materies morbi* has been supposed to be derived from the omnipresent bacterium. Nothing has, so far, been proved. Donders, some five and thirty years ago, removed an injured eye in which one of the long ciliary nerves was entangled in a mass of cicatricial tissue; and to this entanglement, or to the irritation attendant upon it, he attributed the "sympathy" which had been produced. Mooren, about the same time, in removing a wounded eye with the object of preventing sympathetic ophthalmia, bruised the optic nerve in dividing it with faulty scissors; and to this accidental injury he attributed the sympathetic ophthalmia which, in spite of the removal of the wounded eye, was soon afterwards developed. As for bacteria, I have not yet heard that any specific organism has been discovered, either in the eye which has excited the sympathy, or in that to which the morbid influence has been conveyed. With regard to causation, therefore, we are not able to go beyond conjecture; and we are entitled to regard as sympathetic the common form of irido-cyclitis of one eye, occurring subsequently to an injury of the other, only because such a succession of events has been too frequent to be any longer regarded merely as a coincidence. We are very far from being able to affirm that every form of disease occurring in an eye the fellow of which has been injured must be looked upon as a "sympathetic" consequence of the injury. In a great number of cases the balance of probability would, as it appears to me, be rather in the contrary direction. I therefore propose, for the purpose of this communication, to accept Swanzy's definition of sympathetic ophthalmitis, and, at least provisionally, to regard the cases in which disease other than irido-cyclitis or irido-choroiditis has appeared in a sound eye at an uncertain time after disease or injury of its fellow as being open to the possibility of some different explanation.

At this point I should like to enter a modest and gentle protest against the use of the far-fetched and nasty metaphors, "eviscerate" and "exenterate," by which the operation of removing the contents of the eyeball has been described. "Eviscerate" and "exenterate" are good English words, with legitimate although disagreeable meanings; but their metaphorical application to the eye has been "made in Germany." The crystalline lens is not a "viscus," nor are the choroid and retina "entrails." We do not "eviscerate" a filbert, nor do we "exenterate" an egg, nor do we "disembowel" a bottle of champagne. We "empty" the several cavities of their contents, and we do the same with the sclera. Dr. Mules, in his paper, states that emptying the sclera as a substitute for removal of the eye was first suggested, simultaneously and independently, in 1894, by himself and by Professor Alfred Graefe. This is so far an error that the same thing was done by Dr. Noyes, of New York, as early as in 1872, in order to convert a spoilt eye into a good stump for an artificial one.

Having so far tried to clear the ground, I may say that I have performed Mules's operation in about 150 cases. In consequence of the accidental loss of some notes I am unable to

Digitized by Google

state the precise number; but this total is not far from the truth. The patients have been of both sexes, and of ages ranging from nine months to seventy years. Speaking generally, I have been more than satisfied with the results. One loses sight, of course, of the majority of hospital patients; but many of my private patients, after several years, are still wearing artificial eyes with perfect comfort and with natural appearance. There is no irksome pressure from the edges of the artificial eye, no hollow between the upper lid and the margin of the orbit, and no cavity in which secretion accumulates. There is free mobility of the artificial eye in all directions—somewhat less, of course, than that of the natural eye, but sufficient to preserve the correct relative positions in ordinary use. I have lately seen three patients who were respectively operated upon in the years 1886, 1887, and 1888; and to all of them, as well as to more recent cases, the foregoing description will apply. In my early operations, for want of experience with regard to certain details, such as the best size of ball, or the best material for sutures and the best way of inserting them, I frequently failed to obtain complete union; and, with an exception to be presently mentioned, incomplete union always involved the ultimate escape of the ball. Even if the original opening were a mere pinhole it underwent dilatation, as the ball was pressed against it from within by the external ocular muscles, the effect sometimes reminding me of the dilatation of the os uteri by the fœtal membranes. The consequent enlargement of the opening was often very slow, and was always painless until the diameter was nearly equal to that of the ball. It then became painful by reason of the greater force which the muscles were able to exert; and it has been my practice in such cases slightly to incise the margins of the opening and to let the ball come out. The exception referred to was in the case of a man on whom the operation was performed in 1890 for very painful acute hæmorrhagic glaucoma. Two small openings were left with a band of firm tissue between them; and this band so resisted the forward pressure as to prevent the ordinary dilatation from occurring. The patient died from renal disease in 1893, the size of the openings having remained unchanged, and the artificial eye leaving nothing to be desired as regards either comfort or appearance. In a few cases in which openings were left I have endeavoured to close them by a second operation, sometimes immediately, sometimes after an interval, but none of these endeavours were successful. In two instances only, in which the union was originally complete, it afterwards gave way. The first patient was operated upon in November, 1887, he being then past seventy, on account of septic inflammation following a severe wound inflicted by a piece of dirty wood. He came to me in June, 1891, with some irritation of the stump; and I found that he had been wearing the same artificial eye, usually day and night, for the whole of the three and a half years which had elapsed. I had it replaced by a new one, and gave the parts a little rest before this was worn. He came again in February, 1894, the cicatrix having given way and the glass ball being exposed. The second case was that of a man of middle age, on whom the operation was performed in June, 1886, on account of blindness and pain caused by an intraocular growth. Healing was complete, but the patient returned in the following November with an opening and the ball exposed. I let it out, and allowed the scleral cavity, which was perfectly clean, smooth, and white, to collapse. In 1889 he came again, with the stump painful and irregularly distended. I then removed it, and found the distension to have been occasioned by an accumulation of watery fluid, which may previously, in all probability, have produced the yielding of the cicatrix. Even if the ball escapes, whether immediately or after a time, the condition of the patient is infinitely better and more comfortable than after removal of the eye. The stump formed by the collapsed sclera is not so good as that formed by the sclera with a contained ball, but it is in every respect far better than that formed merely by the collapsed muscles. The next best thing to the ball staying in is its coming out; and, except in the case last mentioned, I have never seen any collection of fluid in the scleral cavity, either when the ball was exposed or after it had escaped. I have never seen a single instance of "sympathetic irritation" subsequent to the operation, nor a single instance of "sympathetic ophthalmitis" in the sense of the definition above laid down; but I have seen four cases in which the previously sound eye has subsequently suffered from serious disease, and it may be worth while to describe them with some minuteness.

CASE 1.—A patient, between fifty and sixty years of age, came to me in November, 1891, with advancing cataract of her right eye and with general septic inflammation of the left, apparently the result of an operation for cataract performed a few weeks before at Wiesbaden, whence she had just returned. I performed Mules's operation with good effect, and the patient went to her country home, having arranged that she would come to me for the extraction of the right cataract as soon as this was sufficiently advanced. I saw her once or twice at intervals, her lens gradually becoming more opaque and her vision always corresponding in acuteness with the increasing degree of opacity. At length, in January, 1894, I received a letter saying that she had recently become practically blind, and asking me to fix a day for the operation. On her arrival in town I found the Mules's stump perfectly comfortable, and the right eye, except for the cataract, of perfectly normal aspect, its cornea bright and clear, the iris natural, the pupil mobile, and the conjunctiva healthy; but the perception of light and the projection were less good than they should have been or than the lenticular opacity would explain. The cataract was extracted with absolute surgical success—that is, with prompt healing and the restoration of a perfectly clear pupil; but the sight was very defective, and as soon as the ophthalmoscope could be used it became manifest that the optic nerve was passing into atrophy. The blindness has since become complete.

I confess that I cannot see my way in this case to connect the disease of the optic nerve with the Mules's operation. They may have been cause and effect, but there is no evidence that they were so, and, as it seems to me, very little probability. I have seen hundreds of cases of optic nerve atrophy, sometimes commencing in one eye and afterwards attacking the other, sometimes attacking both simultaneously or nearly so; but this was the only one of them in which Mules's operation had been performed. Unless we are to believe that the operation affords security against atrophy we must, I think, admit that the two events may occur independently in the same individual.

CASE 2.—A girl about eighteen years of age, of highly neurotic temperament and family history, and the subject of a very remarkable degree of habitual constipation, came to me in April, 1890, to ask me to remove her left eye, which had never had good vision, and had lately been destroyed by a succession of attacks of inflammation and ulceration of the cornea, attended by great swelling and thickening of the conjunctiva. After waiting a month to see the effect of treatment I performed Mules's operation on May 5th. All went well for a time, and the patient went to Yorkshire, where, a few weeks later, the right eye became inflamed. Being written to on the subject I advised, early in August, that Mr. Teale should be consulted, and he accordingly saw the patient. On Sept. 10th he wrote as follows: "The eye has proved troublesome and is not yet quite satisfactory. The trouble was essentially conjunctival, and at last became so severe that a peculiar œdematous patch appeared towards the inner canthus, and the neighbouring cornea became opaque, and, in fact, blistered. When everything else seemed to have failed I peritomised the conjunctiva and peeled off the affected surface of the cornea. The early result was good, the cornea healed, and the œdema of the patch of conjunctiva subsided. On the whole, the eye is better, but is still far from well, and is too intolerant of light." It is right to say that Mr. Teale added, "Can the stump of the Mules's eye be causing sympathetic ophthalmia?" I did not think so; and I may assume that if Mr. Teale had held this view at all seriously he would have performed or proposed removal. The patient improved and returned to town, but late in November had an attack of severe and intractable inflammation of the eye, with ulceration of the cornea, which was described to me as being precisely like the attacks by which the left eye had been destroyed. After a period of ineffectual treatment I put her under chloroform, thoroughly scraped the surface of the ulcer, irrigated the eye with mercurial solution, and then closed and immobilised the lids with a pad of wool, retained by adhesive strapping and a bandage. The dressing was not removed for a fortnight, when the eye was apparently well, the ulcer had healed, and the conjunctiva was free from swelling or abnormal vascularity. As a matter of precaution the dressing was re-applied for another fortnight,

Digitized by Google

after which the patient returned to her usual occupations. In a few weeks there was recurrence of ulceration, which again yielded to similar treatment, but which recurred again and again. At last I proposed to close the lids for six months, and for this purpose pared and united their edges, but before the period had expired the patient said that she no longer had perception of light. During the whole time of her illness the eye on which the Mules's operation had been performed never gave her a moment's uneasiness, and was never either congested or tender on pressure. She has continued to wear her artificial eye ever since, and seems hardly conscious of its presence.

In this case it will be seen that the possibility of sympathetic mischief had been present to the minds both of Mr. Teale and myself, and that, to me at least, the hypothesis appeared untenable. I should describe the case as one of corneal disease of peculiar malignity, probably neuroparalytic in its essential character, occurring in a very unfavourable subject, and attacking the two eyes in succession under the influence of some common cause. I cannot find any facts in the history which give the smallest colour to the notion of sympathy, at least in the sense to which I think the word ought to be restricted.

CASE 3.—A girl, about fourteen years of age, went to St. George's Hospital in January, 1887, her left eye being disorganised by chronic inflammation. A Mules's operation was successfully performed, although the patient was so unlucky as to develop scarlet fever a day or two after the operation. This did not interfere with the healing, and she was discharged with a well-fitting artificial eye. In October, 1895, she came to me with interstitial keratitis of the right eye, of the ordinary type and of considerable severity, which ran a very chronic course, and from which she is now making a better recovery than at one time I anticipated. There has never been any tenderness of the Mules's stump, and there has been nothing in the case of the right eye to distinguish it from hundreds of others in which no cause of sympathy could be indicated.

CASE 4.—A single woman, about fifty years of age, had double cataract, for which I operated successfully on both her eyes early in the "eighties." One of them afterwards became the subject of painful and complete glaucoma, and after some ineffectual treatment I performed a Mules's operation upon it in 1887. The remaining eye was attacked by glaucoma in 1894 and was eventually lost. There was nothing to suggest "sympathy" except that the events were consecutive in order of time.

It will be seen from the foregoing narrative that I have met with four cases in which, after the performance of Mules's operation, the remaining eye has been attacked by serious disease. It is remarkable that the four cases were totally unlike in their origin and nature, and that the diseases attacking the second eye were also totally unlike. It is remarkable that neither the ordinary phenomena of sympathetic irritation nor the ordinary phenomena of sympathetic ophthalmitis were exhibited in any one of them, and that in none of them was there any tenderness of the Mules's stump. In most of the cases of supposed sympathy occurring after the lapse of years it has been recorded that the eye by which the sympathy was excited had become tender or painful shortly before the sympathetic outbreak. I am strongly of opinion that if in my cases the eyes on which Mules's operations were performed had been removed instead the subsequent occurrences would have been precisely the same, except that no idea of sympathy would have been suggested. Moreover, it must be remembered that sympathetic ophthalmitis of the ordinary type is by no means unknown after removal of the eye. Many cases of the kind have been recorded, and one of the most recent of them may be found in the *Annales d'Oculistique* for the present year. The question raised by Mr. Cross is one which deserves all the observation and all the acumen which can be brought to bear upon it. On the one hand, the superiority of Mules's operation over removal is as great as the superiority of excision of a joint over the amputation of a limb; and, on the other hand, even this enormous advantage must not be conceded to patients if it be attended by any measurable risk of destructive changes in the eye which remains sound. My personal experience induces me to believe, with some confidence, that the risk is purely imaginary, or, at least, that it has no better foundation than the occurrence of a certain number of coincidences.

Harley-street, W.

ON THE VALUE OF ARSENIC AND BELLADONNA IN THE TREATMENT OF CHOREA.[1]

BY WALKER OVEREND, M.A., M.D. OXON., B.SC. LOND.,
PHYSICIAN TO THE TOTTENHAM HOSPITAL; LATE RADCLIFFE FELLOW.

DURING the summer of 1894 I had an opportunity at the Evelina Out-patient Department of testing the value of arsenic and belladonna in the treatment of chorea. I made notes of twenty-five cases the results of which I have briefly summarised.

CASE 1.—A boy, aged twelve years, had been suffering from chorea for three months. There was no history of rheumatic fever, but the father had been attacked by this disease. There were slight choreic movements of the face and eyes. The apex beat was perceptible in the fifth interspace, half an inch outside the nipple line, and there was a slight bruit audible in that area. Liquor arsenicalis in doses of twelve minims was ordered twice a day. After three days the twitchings were much improved, and after ten days they had disappeared.

CASE 2.—A boy was suffering from a fourth attack. The chorea was slight and limited to the left side, the apex was situated in the fifth space, and there was a long and loud presystolic bruit. Twelve minims of the liquor arsenicalis were prescribed three times a day. After seven days the movements had entirely gone, and oleum morrhuæ with vinum ferri was substituted.

CASE 3.—A girl, aged eight years, suffered from an attack two years previously. There was no history of rheumatic fever, and no cardiac murmur was discovered. There were twitchings of the face, tongue, and eyes. Liquor arsenicalis (10 minims) with bismuth mixture—a combination of subnitrate, tragacanth, and peppermint water—was given twice a day after food. Three days later the dose was increased to 15 minims. This dose, however, was followed by sickness, and a crop of herpes appeared on the lips; it was therefore diminished to 10 minims. After taking arsenic for fourteen days no visible improvement was apparent; consequently the drug was stopped, and tincture of belladonna was tried instead in doses of 15 minims three times a day, along with a carminative. After taking this drug for seven days the movements had disappeared, and tonics were administered in its place. The patient took phosphate of iron for fourteen days and was then discharged, as she had not exhibited any movements during that interval.

CASE 4.—A boy, aged seven years, had exhibited choreic twitchings for a period of three weeks. There was no cardiac bruit and no history of rheumatism, but of fright. After taking arsenic (10 minims) for ten days there was no amelioration. At the end of that time, also, he was sick after each dose, and an acute herpetic eruption with œdema of the right ear appeared. Tincture of belladonna in 20-minim doses with bismuth mixture was ordered every four hours during the day. On the fourth day the movements were decidedly better; after seven days they were no longer present and no toxic effects were observed.

CASE 5.—A girl, aged twelve years, was suffering from the eighth attack. There were now moderate choreic movements of the extremities and tongue which had existed for five weeks. Arsenic in 15-minim doses was prescribed three times a day. There was no cardiac bruit, but the heart's action was markedly irregular. After three days the movements were, if anything, worse; there was some soreness of the eyes and nose, with diarrhœa. Tincture of belladonna (20 minims) along with potassium bromide was ordered every six hours. After four days the movements were much improved; the hands could be held out perfectly still, and only twitchings in the left arm and face were left. The speech was good and the pupils, as is generally the case in chorea, were slightly dilated, but they reacted to light and accommodation. After a week the movements had quite gone. The pupils were then very wide and reacted but slightly to light.

CASE 6.—A girl, aged eleven years, had exhibited frequent and irregular movements of the left arm and leg for a week. There was no history of acute rheumatism, but her father

[1] A paper read before the North Tottenham Medical Society, Nov. 5th, 1896.

Digitized by Google

and brother had suffered from it. She was very anæmic; the apex beat was situated in the nipple line, and there was slight hypertrophy of the left ventricle. Whenever the limbs were thrown into spasmodic movements the heart's action at the same time became markedly irregular. She was ordered 15-minim doses of liquor arsenicalis twice a day. The movements gradually improved, but at the end of three weeks she still complained of much sickness of an evening and of abdominal pain after food. Belladonna, in the form of the tincture in 15 minim doses, with mistura carminativa, was substituted. A week later the movements became *nil* and did not reappear.

CASE 7.—A girl, aged eight years, had a fright three weeks previous to admission to hospital. There were movements of the hands and tongue. The heart sounds were normal, but the cardiac movements became irregular when the jerks occurred. A week's treatment with arsenic only appeared to aggravate the condition; she complained also of sickness, headache, and of an eruption around the mouth. Tincture of belladonna in 15-minim doses with peppermint water was prescribed instead. After a week the note read: "No vomiting, no headache, movements the same, pupils normal, herpes drying up." After three days' further treatment the movements were vastly improved, and after fourteen days had completely disappeared.

CASE 8.—A girl, aged eleven years, was suffering from a second attack, which was apparently the result of an examination at school. The left face and tongue were particularly affected. After three days' treatment with arsenic diluted with cinnamon water the eyes and nose became very sore, and tincture of belladonna in 10-minim doses was ordered three times a day in place of it. After three days the movements had subsided considerably, and after ten days' treatment the movements were extremely slight. She complained of blisters in the mouth and of a sore throat. Oleum morrhuæ with vinum ferri was now ordered instead. It is advisable, especially in the case of out-patients, to discontinue the arsenic and belladonna as soon as the movements become insignificant, and then to give tonics in order to complete the cure. The remaining cases were much of the same character, and illustrated in the same manner the efficacy of these drugs.

During the last year eight cases of severe chorea, including one of chorea insaniens, have been admitted into the Tottenham Hospital. Condensed notes of three of these read as follows:—

CASE 9.—A boy, aged ten years, was admitted on Feb. 8th, 1897, with extensive choreic movements affecting all the muscles of the face, arms, and shoulders. Contractions of the sterno-mastoids caused him to turn his head from side to side. He had spasmodic and very violent movements of the trunk. Breathing and swallowing were unaffected. The heart's action was rapid, the pulse 90, but there was no murmur. A mixture of 30 minims of tincture of belladonna, and 6 minims of liquor arsenicalis, with mistura bismuthi, was prescribed every four hours. On the 11th he became a little quieter, slept during the day for a few hours, and well at night. He took food well. On the 12th he was much quieter, but if observed the movements became exaggerated. On the 13th he was much better; most movement was now to be seen in the lips and tongue. The first sound was reduplicated at the apex. There was some swelling of the parotids, and the urine measured 12 ounces. Potassium acetate in 5-grain doses was added to the mixture. On the 14th he was decidedly quieter, and the urine measured 18 ounces. On the 16th he was very much quieter, and no oscillations occurred unless he attempted to move. The urine amounted to 16 ounces. Syrup of phosphate of iron was now ordered and the arsenic and belladonna were discontinued.

CASE 10.—A girl, aged seventeen years, was an out-patient with chorea twelve years previously. She was frightened in February by a carriage accident, but no movements were perceptible until April 8th. On admission on April 14th she was exceedingly violent and restless, and the movements affected the limbs chiefly. The temperature was 99·2°F. On the 15th a mixture of 30 minims of tincture of belladonna, 6 minims of liquor arsenicalis, with bismuth mixture, was administered every four hours after food. On the 20th the movements had entirely disappeared. Massage to the arms was commenced and cod-liver oil with phosphate of iron was prescribed instead.

CASE 11.—The case of chorea insaniens occurred in a girl, aged fifteen years, with a history of rheumatism at the age of five years. The movements commenced about five days before admission. The knee-joints were swollen. At the height of her violence chloroform was administered; she was taking belladonna for three days before, and subsequently for a week. At the end of this time she could walk, and all movements had ceased.

When estimating the value of a drug much care is required, and especially is this the case in chorea, since the natural tendency is towards recovery after about seven weeks, even if no treatment at all is adopted. If a drug is prescribed, and after a few weeks' perseverance it is found to be of no benefit, it is natural to seek a change, and the latter drug may receive the credit of the cure, which might have followed even if no drug had been administered. The observation of the cases here mentioned gives one the impression, however, and this is also generally acknowledged, that large doses of arsenic have a beneficial influence in subduing the movements, and this is best seen after the movements have existed for some time—weeks or months—that is, when a cure seems almost hopeless. The drug should be given after food, and the little patient should lie down for half an hour afterwards in order to avoid retching and sickness. Whilst looking up the literature I found a paper by Dr. Fuller, in the *Medical Times* of July 1st, 1859, on the Treatment of Choreic Patients by Belladonna. He gave large doses of the drug in twelve cases. One girl aged ten years, received 70 grains of the extract daily, the average dose for an adult being half a grain. She took 1000 grains in twenty-six days. Another took 37 grains of atropine in eighteen days, the average dose for an adult being one-fiftieth of a grain. During the administration neither fever, rash, nor erythema was noted. The pulse became quick and the urine scanty. Only in two instances was indistinctness of vision observed; four suffered from sickness and diarrhœa. There was no dryness of the throat, no headache, and no delirium. In two patients the belladonna was useless; in the remainder its efficacy was noteworthy. The drug was readily absorbed from the stomach and passed out in the urine, from which it could be extracted. The phenomena of chorea appear to be due to a nutritive and functional disturbance or ataxia of the higher nerve centres. Post mortem a general tendency to dilatation of the smaller arteries within the substance of the brain accompanied with exudation is observed. This appears more especially in the corpus striatum and the regions supplied by the middle cerebral arteries; in other words, there is pronounced hyperæmia of these nerve centres. It is probable that the chief stress falls upon the Rolandic areas. Such vaso-motor ataxia might be induced by reflex disturbances arising within the digestive tract, by uterine irregularities, or by emotional disturbances. In the rheumatic diathesis the toxin may attack the motor centres directly.

It is, perhaps, permissible to make the following remarks in conclusion:—1. Belladonna appears to be most beneficial in recent cases, and its influence is sometimes very marked in severer forms. 2. In obviously rheumatic cases arsenic in large doses may be given a trial or may be combined with belladonna from the first. Belladonna may act by diminishing the excitability of the nerve centres or by imparting an improved tone to their vascular supply. 3. In the wards of a hospital it is perfectly justifiable to give to a child as much as 30 minims or more of tincture of belladonna every four hours for ten days or even longer. Certain precautions are necessary. The patient should be kept in bed and the urine should be daily measured. Small doses of potassium acetate may be added if it become much diminished or if the eyelids show any puffiness. In one child nocturnal incontinence occurred, and the dose was lessened. The occurrence of the papular erythema, which leaves raised circular lumps for a time, does not necessitate any diminution of the dose. Dryness of the throat and swelling of the parotids, should they occur, are merely temporary. The influence of the belladonna makes itself felt after about four days. Should no visible improvement occur before the tenth day it would be useless to continue with it. But in all the eight severe cases already referred to belladonna was of benefit, and is certainly worthy of further trial. As soon as the movements become trivial or occur only during exertion it is better to omit the belladonna, to commence massage of the affected muscles, and administer cod-liver oil and syrup of phosphate of iron or other tonics. The arsenic may be continued for a week or longer. For permission to publish the cases seen at the Evelina Hospital I am indebted to the courtesy of Dr. Soltau Fenwick, assistant physician to the hospital.

VITALITY.[1]

BY LIONEL S. BEALE, M.B., F.R.C.P. LOND., F.R.S.,
EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN KING'S COLLEGE, LONDON, AND CONSULTING PHYSICIAN TO THE HOSPITAL; GOVERNMENT MEDICAL REFEREE FOR ENGLAND.

VII.—THE INTERSTITIAL CIRCULATION IN ALL LIVING THINGS.—ITS DEPENDENCE ON VITALITY.

INTIMATELY associated with the matter of every living particle is water. Indeed, water is a constant and necessary constituent of all life. Its amount is considerable in proportion to the solids wherever vital phenomena are active. Living matter without water has probably never existed, and anything approaching desiccation results in death. Water, then, must be regarded as an absolutely necessary condition of life at all times, but the smallest amount that may be present without life ceasing has not been determined. As far as I have been able to ascertain, no evidence yet obtained supports the conclusion that life in the complete absence of moisture is possible, and it seems almost certain that water must have preceded the existence of any form of life.

Life involves the very free movement not only of material particles but of the constituent atoms of the living matter, many of which are being continually rearranged—placed in new positions with respect to one another. There is no such thing as a living particle having the same composition in every part, or remaining of the same composition from moment to moment. An isolated living atom of any substance in nature is not conceivable.

Whether the atoms are caused to move in the water in which they are suspended or are in some sort of chemical or other kind of combination with the elements of the water cannot be decided at present. The atomic movements and rearrangements here referred to are *vital movements*, but are, of course, invisible and not to be demonstrated; but the general movements so characteristic of living matter are well known, and can be studied without difficulty in the amœba, in the colourless blood corpuscles, in pus and mucus corpuscles, and in many other particles of living matter or bioplasm; and these movements of living matter differ in essentials from every kind of movement known to take place in matter in any other state or condition, and are vital—that is, peculiar to, and characteristic of, life—the temporary living state of matter.

Not only is water necessary to living matter, but the fluid which bathes the living matter and the substance immediately around it must be continually changed. It is probable that neither the particles of living matter nor the fluid around it are ever in a state of rest—stagnation of fluid like the cessation of movement in living matter being immediately followed by death.

In all living forms there is evidence of the free and constant movement of interstitial fluid, and in organisms of complex structure consisting of tissues as well as of living matter the fluid is not only present in the living matter itself, but pervades every part of all the moist tissues, circulating freely among the structural elements, and keeping these in a state of health and activity. In some cases there are actual canals which are bounded by a thin layer of the tissue and thus separated from one another; in others the fluid pervades every part of the tissue, occupying minute interstices, which vary much in dimension and arrangement in different tissues, and in the same tissue at different ages. The free movement of fluid is, in fact, always taking place in living forms, whether there are true vessels arranged as a network of tubes in every part of the organism, or propelled by a special organ into large vessels directly connected with it, and so into smaller ones resulting from the division and sub-division of the trunk and its branches, and thus distributed to all parts. The free circulation in the living matter and in the interstices of the tissues is universal, and is one of the phenomena belonging to life itself. It is an "interstitial circulation," always independent of any propelling organ or power, or capillary attraction, adhesion or any motor action known in connexion with the non-living.

This unceasing movement and interchange of fluid which takes place in the minute channels and interspaces between the microscopic elements of the tissues as well as in every kind of living matter is a necessity of life, and has been universally present in all things that have lived, including the most minute speck of independent living matter and the most gigantic and highly complex organisms. The interstitial circulation goes on even in the so-called non-vascular tissues which may be situated some distance from any vascular supply—from any blood- or lymph-carrying vessels. Even in the hardest textures, such as bone, and teeth, and shell, the circulation of interstitial fluid continues as long as any living particles, however minute, which have taken part in the formation of the tissue, remain. When tissue becomes hard, and dry, and inactive, there is, of course, no longer circulation of fluid in its interstices, and all changes indicative of life have ceased; and though still connected with and, in fact, forming part of a living organism, the tissue is no more living than if it had long been completely severed and preserved for many years in a museum. Through the agency of the interstitial circulation all nutrient matters after passing through the formed material are brought into close proximity with the particles of bioplasm that are to appropriate them, which living particles are concerned in the development, formation, and action of the respective tissues or organs. By the interstitial circulation the deterioration of tissue may be prevented, and damage which it may have sustained repaired. Abnormal formations and deposits may be removed through the circulation of the interstitial fluid, and may be taken up by it, changed, and dissolved. Although entirely independent of the organs of circulation and of any propelling power, mechanism, or apparatus, some of the interstitial fluid with its dissolved constituents is continually passing through the capillary walls where capillaries exist and mixing with the blood, some of its components taking part in nutrition while others are altogether removed from the organism by the action of various excreting organs.

The interstitial circulation of man and the higher animals is active long before the organs of circulation or the fluid to be propelled through the vessels exist, and before any vestige of the complex arrangement of nerve centres and fibres which regulate and control the blood circulation can be discerned. In fact, the ordinary circulating organs may be said to be subordinate and to minister to the interstitial circulation, and would have no meaning in the absence of the latter, which begins at the earliest period of embryonic life and before any structures or organs have appeared. The interstitial circulation never ceases as long as life lasts, and continues for a time after the heart has ceased to beat and the blood to circulate. In various pathological changes detrimental to some of the tissues and organs of the body of *vital importance* the interstitial circulation may still be carried on, but in its absence, development, nutrition, formation, repair, action, and the removal of the products of disintegration and decay would be impossible.

That "death" occurs when the heart stops beating and the blood ceases to circulate is certainly true with regard to the high and complex phenomena which characterise man and the higher animals, but some vital actions continue to be manifested in certain organs and textures after death in the ordinary sense has taken place. The formation of hair, nail, bone, and some other structures may continue for some time after death. In short, although the bioplasm of certain parts has ceased to live, that of certain tissues and organs of the body may retain its vitality for some time, which varies according to circumstances. The bioplasm concerned in the higher operations of the brain and some other parts of the nervous system may indeed be dead, while other forms of bioplasm continue to live, and for different periods of time after "death." In man and the higher animals the forms of living matter dying first are more dependent upon the steady supply of nutrient matters and the immediate removal of the products formed during their vital changes than the bioplasm taking part in the formation and action of simpler tissues and organs, and probably "die" the instant the interstitial circulation in them ceases to be carried on at the normal rate. "We" die some time before the death of many of the living particles taking part in the formation and action of some of our tissues occurs. In certain cases, as is well known, the multiplication of particles of bioplasm (leucocytes) continues for some time after death, and is associated with a rise in the temperature of the whole body amounting occasionally to three or four degrees during several hours after the blood circulation has

[1] Nos. I., II., III., IV., V., and VI. were published in THE LANCET of Feb. 22nd, April 11th, June 13th, Aug. 29th, Oct. 17th, 1896, and Jan. 23rd, 1897, respectively.

ceased for ever. It must, however, be borne in mind that every form of bioplasm belonging to the organism has been derived by direct descent from one minute living particle.

(To be continued.)

NOTES ON SMALL-POX, VACCINATION, AND RE-VACCINATION.

BY FREDERICK W. LOWNDES, M.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL POLICE.

THE value of vaccination and re-vaccination in preventing and diminishing both the prevalence and mortality of small-pox must be to members of the medical profession a matter of experience. In the following notes I have given mine for what they are worth. If other practitioners would give theirs it seems to me that valuable additional material might be added to that already furnished by the report of the Vaccination Commission.

During my student career, 1860–65, I only saw one case of small-pox, and that a doubtful one, though I saw many cases of typhus, typhoid, and scarlet fevers, measles—in short, all the other exanthemata. Liverpool at that time was a hot-bed of typhus fever, its victims comprising many medical practitioners, young, old, and middle-aged; now there are middle-aged physicians who have never seen a case of typhus fever, it being so comparatively rare. But ought not small-pox to be equally so? In the spring of 1866 I was assistant to Mr. G. C. Holt, who was then practising in Tunstall, Staffordshire. During the three months I remained with him I saw many cases of small-pox, which was then very prevalent, and the cause was very easy to find. Not only was vaccination much neglected, but it was very inefficiently performed, the public vaccinator yielding to the wishes of the mothers and only producing two, or at the most three, vesicles. As the neighbourhood was a great one for tramps nothing could be easier than the importation of the disease. I saw several cases of the confluent form ending fatally. What surprised me most was the perfect indifference of the inhabitants to such a scourge, the child, either unvaccinated or only very imperfectly protected by it, being allowed to play about in the room in which the father lay a ghastly object even for a surgeon to behold; but all remonstrances were vain. For myself I felt no fear whatever, having been not only efficiently vaccinated in infancy (the marks of which were then quite distinct), but having also been re-vaccinated eight years previously during an epidemic of small-pox in Liverpool. This was so successful as to convince me even then that vaccination in infancy, however efficiently performed, can only be regarded as a protection up to puberty, and possibly to the age of twenty-one years, but not later. At the time of which I am writing re-vaccination was almost unknown in Staffordshire and elsewhere in England. During the rest of this same year, 1866, I was in Birmingham as one of the resident surgeons of the lying-in hospital in that town. Though my duties took me into the very worst and poorest parts of the town I neither saw nor heard of any cases of small-pox, and I learned incidentally that vaccination was most efficiently performed there. During the year 1867 I resided in Burford, Oxon., as assistant to Mr. T. H. Cheatle, who had been practising there for some years. I am glad to state that he still practises there, occupying a very honourable position both among his professional brethren and the residents of his native town, in which he has practised for more than forty years. Shortly before my arrival at Burford a fatal case of small-pox had occurred at one of the neighbouring villages, which was the subject of conversation. It formed an addition to the illustrations of panic and selfishness which have so often distinguished the conduct of people during the prevalence of small-pox. Instead of the indifference I had seen in Tunstall the farmers and other employers of labour had such a dread of the disease that they refused to allow any of their labourers to go near the house wherein the infected man lay, while at his death the relieving officer was obliged to take men from Burford, a distance of three miles, to put the body in the coffin. In consequence of this and other warnings elsewhere vaccination was vigorously pushed, instructions being to vaccinate in three places on each arm, I having been taught to do the same in four places at the vaccination station in Tottenham-court-road, London, two years previously. It has the advantage of securing marks on both arms as well as the thoroughly efficient vaccination of the infant. But I have never seen it done since, and it seems to me that four good marks on the left arm are sufficient for all practical purposes. No other case of small-pox occurred in or near Burford during the year.

When I began practice in Liverpool at the end of 1868 I assisted the late Dr. Steele, Dr. Lodge, and Dr. Roger Parker in their vaccinations. At that time a large number of vaccinations were performed yearly by the surgeons of the Ladies' Charity, of whom Dr. Steele was one, it being a rule that no woman should have the benefit of the charity in a subsequent labour unless the child had been vaccinated. Later the consolidation order took effect, the vaccinations at the Ladies' Charity ceased, and three public vaccinators performed the vaccinations formerly done by the twelve district medical officers. Dr. Lodge was the public vaccinator for Everton, a very large district. A Welshman himself, he used to say that Welsh women gave him the most trouble in demanding to have their infants vaccinated in only two places, and I have seen him show them triumphantly a child with six, or even nine, multiple vesicles on the arm, without any more areola, or constitutional disturbance than in those who had only four. I had very good opportunities of seeing the various forms of vaccination by grooved needle, by parallel incisions, by parallel scratches, and by simple punctures. On the whole I have found the parallel scratches, as recommended by Dr. Seaton and Dr. Renner, the most satisfactory. It was somewhat remarkable that soon after the new arrangements had been made and that vaccination had been most rigorously enforced we should have been visited by a very severe epidemic of small-pox. I was then one of the district medical officers, my district comprising some of the worst parts of Liverpool. A great improvement has taken place in it since, whole streets having been removed and houses of a much better class built on the sites. I saw a very large number of cases, some of them being of the most severe confluent form. Abler pens than mine have dealt with this epidemic, and I will limit myself to what came under my own notice. We had not then the Public Health Act of 1875, and had only limited powers as to the removal of patients to hospital and of corpses to the mortuary. I have a very vivid recollection of attending a man day after day lying in the room where also lay the dead body of his child—a victim to the fell disease. I remember, also, how when the disease was at its height men and women invaded the vaccination stations in hundreds and thousands to secure re-vaccination, which to not a few was really primary vaccination. Careful note was made as to vaccination marks in all those who were admitted into hospital, the result being to confirm all the various and subsequent experience of the value of vaccination in reducing the number of those infected and the virulence of the disease. At length, when the re-vaccinations had continued for some time and a very large proportion of the whole population was fully protected, the epidemic ceased, just as it did more recently both in Warrington and in Gloucester. Since then we have had cases of small-pox now and then, and not long ago there was a sufficient number to cause a scare. But thanks to the notification of each case and to the prompt measures taken by Dr. Hope, the medical officer of health, to ensure immediate removal to hospital when this was possible, and isolation when it was not, as well as to the prompt vaccination of infants and re-vaccination of adults, the disease was prevented from spreading. In such a city as Liverpool there must in the very natural course of events always be a very large number of infants under the age of three months, which, added to others not vaccinated from other causes, furnishes a considerable number of unprotected children, among whom a case might be imported at any time.

And re-vaccination is by no means so generally adopted as it ought to be. In 1877 I was appointed surgeon to the Liverpool police force, one of my duties being to examine all candidates for the force. I was struck with the circumstance that excepting those who had been in the army or Royal Irish Constabulary hardly one had been re-vaccinated, while in not a few men there was an entire absence of any vaccination scars. I found that it had been the practice previously to re-vaccinate the whole force in times of small-pox epidemic. But it

Digitized by Google

seemed to me much more desirable that each candidate, after being found fit to be admitted into the service, should be re-vaccinated (unless this had been previously done) before commencing his duties. Now, as everyone knows, police officers are very apt to be brought in contact with small-pox patients exposing themselves in the streets before they are cured, or detained at a railway station or other public place. Most important is it, therefore, that every police officer should be thoroughly protected by vaccination and re-vaccination. About ten years ago my late colleague, Dr. J. S. Clarke, and I examined the arms of all members of the force. We found that very few had been re-vaccinated, and that many had no marks whatever. We recommended that the whole force should be re-vaccinated and that every candidate should be re-vaccinated before admission if the examining surgeon found this to be necessary. Our recommendations remained disregarded until the beginning of the year 1895, when the Watch Committee resolved that every officer then in the force should be re-vaccinated by the examining surgeon, but that this should be voluntary on their part. The committee also resolved that every candidate should be re-vaccinated before admission if the examining surgeon deemed this necessary. This is the rule enforced in the Royal Irish Constabulary and in the Metropolitan Police Force, London. It seems to me worthy of adoption in every police force, whether large or small. For until it has been a rule absolute re-vaccination will never become general. Only thirty-seven constables came to me voluntarily to be re-vaccinated, while 176 men who have joined the force since 1895 have received certificates from me of successful vaccination. They being men between twenty-one and thirty years of age present marks of very efficient primary vaccination. But I generally find excellent results of re-vaccination, both in those vaccinated by their own surgeons and by myself. I always use calf lymph, and endeavour to secure two good marks. In the course of ten or twelve years every member of the Liverpool police force will have been re-vaccinated, and though it is to be wished that this very desirable regulation had been effected before, it is very satisfactory that it has been done now. The chairman and members of the Liverpool Watch Committee as well as the Head Constable deserve great credit for bringing about so very desirable a reform, which was not effected without considerable opposition.

I cannot help thinking that if every individual member of the profession did his best in his individual and professional capacity to promote re-vaccination in his household and among all with whom he is brought professionally in contact we should very soon hear the last of small-pox epidemics and anti-vaccinationists. I have given my experience for what it is worth, but there must be many practitioners in town and country who can give even more convincing proofs of the value of Edward Jenner's work, accomplished so happily 101 years ago.

Liverpool.

SUBCUTANEOUS EMPHYSEMA FOLLOWING LABOUR.

BY CHARLES D. MUSGROVE, M.D. EDIN.

ALTHOUGH the above condition is by no means rare it is sufficiently uncommon to be worth recording, the more so in this particular case on account of a peculiarity in the onset of the symptoms.

A primipara, aged twenty-two years, was confined on May 22nd, 1897. The presentation was left occipito-anterior and the labour a natural one, except that it was somewhat prolonged, especially in the later stages, owing to the large size of the child's head. From the time when the head had descended low enough to be visible at the vulvar opening it was nearly an hour before delivery took place, and during this period the pains were violent and almost constant, whilst the patient, who was strong and well built, exerted herself to the utmost in holding her breath and bearing down forcibly. After the head was expelled, which occurred at 6.30 P.M., the remainder of the labour was satisfactory. During the night the patient rested quietly, with intervals of sleep, until 4 A.M., when she was seized with a pain at the left side of the trachea about an inch above the sternal end of the clavicle. This continued for an hour, after which it passed off almost as suddenly as it had come on. Neither at this nor at any other period in the progress of the case was there any dyspnœa. When I saw her at 10 A.M. she had no pain or discomfort, her breathing was quiet and natural, and her temperature was 98° F., but her pulse was intermittent and irregular, though not rapid. On examination over the part indicated by her as the seat of the pain, which had occurred at 4 A.M., no swelling or tenderness was found, but in each supra-clavicular region and over the whole of the front of the chest there was felt and also heard on palpation marked emphysematous crackling of the subcutaneous tissues. The percussion note over the whole extent of the lungs was normal in character, and the lung sounds were distinctly heard, so that there was evidently no pneumothorax present.

Taking into consideration the fact that the emphysema of the subcutaneous tissues occurred within fifteen hours of the termination of labour, it is evident that rupture of one or more vesicles of the lung had taken place owing to the severe and prolonged straining during the hour preceding the expulsion of the head, and that the air having been effused beneath the visceral layer of the pleura, and probably also between the lobules of the lungs, had found its way to the mediastinum and thence to the neck. It is to this latter part of its course that I desire specially to draw attention, as offering a feasible explanation of the attack of pain, which formed the onset of the symptoms. It is evident that in the mediastinum air which has been effused from the lungs must be on the outer aspect of the pericardium, and therefore outside that layer of fascia, which is continuous with the fibrous layer of the pericardium, and which, as it is traced upwards, is found to invest the trachea and thyroid gland. Its readiest mode of passage from the chest to the neck would appear to be through the looser tissue lying at the back of the sternum, and if so it would make its way upwards on the inner aspect of the fascia, which is attached to the posterior aspect of the sternum, and which is continued upwards to invest the depressors of the hyoid bone; in this case a conclusive proof was afforded that this was the course which the air had taken, for on applying a stethoscope over the upper part of the body of the sternum a distinct crackling was heard with each beat of the heart, of which only one explanation is possible, viz., the presence of air in the loose tissue lying behind the bone. Taking these facts into consideration there seems every probability that after the air had reached the neck it lay between two layers of fascia, a posterior covering the trachea and an anterior investing the sterno-hyoid and sterno-thyroid muscles, and it is to the pressure of the air as it was gradually forced up from the chest into this compartment that I would ascribe the attack of pain in the neck, for whereas the entrance of the air from below would be comparatively easy, its escape from the compartment in which it would find itself would be a matter of considerable difficulty; in fact, it appears to me that there would be only one way of escape—viz., by forcing itself through the anterior wall of fascia at the point where the latter is pierced on each side by the external jugular vein. It may have been that while the patient was asleep this vessel was somewhat engorged owing to the position of her head, thus preventing the escape of air alongside of it. If this assumption be correct it can readily be understood that the pain due to the stretching of the fascia by the increasing volume of air behind it having awakened the patient, the movements of the latter, by varying the amount of blood in the vein, would tend to facilitate the escape of the air, thus accounting for the disappearance of the pain. The air, having once reached the subcutaneous tissues, would, of course, be able readily to diffuse itself over the neck and chest.

Of the further progress of the case little remains to be said. The crackling produced on palpation gradually became less marked, until on the seventh day it had disappeared, whilst that heard with the beat of the heart continued for two days longer, after which it also ceased, so that by the tenth day the whole of the effused air had evidently been absorbed.

Penarth.

THE Queen has been graciously pleased to accept the original copy of Surgeon-Lieutenant-Colonel John MacGregor's Jubilee poems entitled "*Victoria Maxima et Victoria Regina*" A cover was specially designed and embroidered by Mrs. MacGregor.

A METHOD OF OBVIATING RECURRENCE AFTER OPERATION FOR SYMBLEPHARON.

BY KENNETH SCOTT, F.R.C.S. EDIN.

THE circumstances under which this special form of treatment was called for occurred in a peculiar case, very similar to some others which I recently had occasion to describe,[1] in which there were adhesions between the cornea and palpebral conjunctivæ due to a specified cause. The patient was an Egyptian peasant, twenty-seven years old, and of strong, healthy constitution. He acknowledged having suffered from inflammation of his left eye some six months previously, and having then employed a white "sheeshm" for its cure. White "sheeshm," as I have elsewhere stated,[2] is a dry powder, usually composed of powdered alum, calomel, sugar, and flour, and is one amongst a variety of others employed by the lower Egyptian peasant class as a dry collyrium, which is introduced inside the eyelids when there is inflammation of the eye; needless to say the result is usually more harmful than beneficial. The patient's left eye when I first saw it presented a slight ptosis, which, on closer examination, was found to be caused by the upper eyelid and cornea being firmly adherent to each other. The point of junction between the two surfaces was restricted to a spot, about 4 mm. in area, situated on the outer third of the horizontal diameter of the cornea. The band of connexion was fleshy, very short, and corresponded in girth to the size of its corneal attachment. The introduction of a tenotomy hook demonstrated that the adhesion was strictly limited to this one point. During the operation I rendered the band tense with a tenotomy hook and then carefully dissected it off from the cornea with an angular keratome. I also find this knife convenient to use for a similar purpose when operating on cases of pterygium. In the dissection I was careful to remove a very slight thickness of the anterior corneal layers, so laying bare clear corneal tissue and also making certain that no opaque débris of cicatricial tissue should be left behind. I then everted the upper eyelid and with scissors removed the remainder of the band. I have always found it very difficult to keep any form of dressing or other material in place which has been introduced temporarily with the object of keeping the two opposing conjunctival surfaces apart during a process of healing. There were no thin glass shields at hand which might have answered this purpose, but which have also the disadvantage of, to a certain extent, acting as foreign bodies under the eyelids. In consequence I was compelled to devise some other means for attaining my object, and succeeded by everting the upper eyelid and stitching its ciliary edge in that position to the eyebrow. The sutures employed were of very fine silver wire, as that material seemed to be the best for the purpose, being recommended by its complete pliability, its being so readily fastened by twisting, and, if necessary, being undone and readjusted; it was also recommended by the thorough way in which it can be rendered aseptic. The patient's eye was now treated as a case of extensive corneal abrasion. Atropine was instilled, and a plain dressing with vaseline and a sprinkling of dermatol was kept applied to the eye. The healing of the denuded portion of cornea was carefully gauged each day by the use of fluorescin, and when the process was completed after the lapse of four days the retaining sutures were removed.

I have similarly applied the principle of this method with marked success in a case of symblepharon posterius, in which class of cases—contrary, I believe, to general usage—I always remove flaps of bulbar conjunctiva and attach them by buried sutures to the inner surface of the eyelid, as I find by experience that the recuperative power of a denuded portion of the bulbar conjunctiva is much more speedy and satisfactory than that of a corresponding area when situated on the eyelid; besides, by attaching the flaps to the bare inner surfaces of the eyelids any tendency to cicatricial contraction is avoided, which might otherwise lead to subsequent inversion of eyelashes, &c.

The small detail of operative procedure described above may possibly have been used by other surgeons, but as hitherto I have not found mention of it I may perhaps be allowed to recommend it on account of its great simplicity, efficiency, and practical painlessness. The cornea is protected by the dressing from extraneous influences, and has every opportunity of healing uninterruptedly, thus avoiding one of the chief causes of anxiety which the surgeon has frequently to encounter in these cases.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CONGENITAL CYST OF THE NECK OF DOUBTFUL NATURE.

BY P. CLENNELL FENWICK, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

MR. G. E. DEAMER recently delivered a patient of a healthy male child and immediately noticed a tumour on the right side of the neck. He asked my opinion of its nature, and I have thought that a note of the case might find publication in THE LANCET.

The tumour was at birth of the size of a large chestnut, and was situated between the sterno-mastoid and thyroid body—limited sharply above by the lower jaw, and showing several swollen veins running over its surface. The anterior border of the sterno-mastoid overlapped it. At five weeks old the tumour was swollen (about the size of a large walnut) and was lying close to the thyroid gland, while between it and the gland a hard, round cord could be defined, apparently attached to the right lobe of the thyroid and to the back of the growth. The swelling was hard and round, and felt like a tense cyst. There was distinct pulsation perceptible to the eye, and the cyst moved up and down on swallowing. When the child cried it increased in size, but returned to its original dimensions when the infant was quiet.

The diagnosis of the growth is obscure. Owing to its close communication with the thyroid, its entire mobility and its rapid variation in size, I was inclined to think it was an unobliterated branchial cleft, but I was unable to account for the pulsation, which was certainly *not* transmitted from the underlying vessels.

As neither Mr. Deamer nor I have seen an exactly similar case we should be glad of any assistance in arriving at a correct diagnosis, for which purpose, with his permission, I send this note.

Christchurch, New Zealand.

A CASE OF UTERUS BICORNIS.

BY JAMES B. TOMBLESON, M.B., B CH. OXON.,
SENIOR OBSTETRICAL HOUSE PHYSICIAN, ST. THOMAS'S HOSPITAL.

I HAVE recently had under my care a case of uterus bicornis, with gestation in one horn, which I think worth reporting. The patient was being attended in her confinement by an obstetric clerk from St. Thomas's Hospital, who sent for me as he thought that the case was a curious one of twins. On abdominal examination I found a large, almost symmetrical heart-shaped tumour, reaching on each side nearly up to the costal margin. There was a deep central sulcus separating the two halves, of which the right was rather larger than the left. I decided that probably a fœtus lay in each half of the tumour, which I had no doubt was the uterus, and as the pains were not very numerous or powerful I left the patient, resolving to see her later. Some hours

Digitized by Google

later the obstetric clerk sent for me, stating that a child was born and that he believed a second one was present, lying transversely across the pelvis. I found on examination of the abdomen that in place of the earlier tumour a much smaller one was now to be felt lying across the lower part of the abdomen. In the middline it reached three inches above the symphysis pubis. The most prominent part was a round, firm mass in the right iliac fossa the size of a cocoa-nut, and from this the mass gradually tapered away towards the left iliac fossa, where it was about two inches thick. As a result of this examination I thought the clerk was probably right, and prepared to do internal version under an anæsthetic. On getting my hand into the vagina (the insertion of the whole hand was necessary as the cervix was very high up) I found that the uterus contained only the placenta and some blood-clot. I made a careful examination, and found that the uterus consisted of two horns, which united only at the cervix. Of these, the right was capacious and had evidently contained the fœtus, while the left was much smaller in calibre, admitting two fingers for a distance of two inches and one finger for three and a half inches. The placenta was detached when the examination was made, but from its position had probably occupied the left cornu. No septum was to be felt on either anterior or posterior wall of the cervix. On inquiry I learned that the patient had been confined twice previously, that on each occasion the child was premature (in this case early seventh month), and that on each occasion, too, an erroneous diagnosis of twins had been made by the attending practitioner. In this latter fact, it seems to me, lies the chief interest of the case, and it is in the hope that my account of this case may prevent others from making a similar mistake to my own, that I have ventured to send this report.

Albert Embankment, S.E.

A NOTE ON THE TREATMENT OF HEART DISEASE BY THE ADMINISTRATION OF BARIUM WATERS COMBINED WITH THE NAUHEIM SYSTEM OF BATHS.

BY W. BLACK JONES, M.D., B.S. LOND., D.P.H.

THE treatment of cases of heart disease by the administration of barium waters combined with the Nauheim system of baths having been carried out at Llangammarch Wells during the past three years, the following case may be of interest to the readers of THE LANCET.

A man, aged thirty-four years, engaged in office work, consulted me in April last. There was a history of the patient having suffered from chronic rheumatism, but his present trouble had existed for about a year, during which time he had complained of dyspnœa and palpitation, pulsation in the cardiac region and carotids being constantly present, even at night. His appetite was poor, and the bowels were irregular. He presented signs of aortic stenosis, mitral regurgitation and dilatation, the apex beat being in the nipple line, with a heaving impulse. The pulse was regular, with rather an increased tension. The urine was normal. The treatment consisted in the administration of barium water, Nauheim effervescing baths, rest, and careful dieting. He began to improve in a few days, and after three weeks' treatment it was noticed that the apex beat had retracted to a point half an inch within the nipple line; there was a corresponding diminution in the area of cardiac dulness, and the pulsation was less forcible. The effect of the baths was shown by the following average of eight successive observations on the pulse rate; the rate after resting for half an hour before the bath was 74·1, that immediately before leaving the bath was 71·3, while that after resting half an hour after dressing was 66·5. This diminished rate was found on several occasions to remain constant until the evening. Shortly before leaving Llangammarch he stated that he was quite free from any kind of throbbing or other inconvenience, a condition which he had not experienced for many months.

This improvement I consider to be due to several factors which are afforded in this place, chief among them being the mineral water, the baths, and rest.

Llangammarch Wells.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propriis collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. MARY'S HOSPITAL.

A CASE OF TYPHOID FEVER WITHOUT ULCERATION OF THE INTESTINE.

(Under the care of Dr. CHEADLE.)

FROM time to time cases have been met with which during life had been diagnosed as typhoid fever; but when, post mortem, no intestinal ulceration was discovered the diagnosis was doubted. Dr. Sidney Phillips has recorded two cases in which, though Peyer's patches were swollen, yet there was no ulceration even as late as the twenty-first or twenty-fourth days respectively of the disease.[1] A similar case is reported in *La Semaine Médicale*.[2] The following case, though resembling the cases already quoted, differs from them in several important particulars. At the necropsy no sign of any disease of Peyer's patches could be seen; if this case had occurred only a few years ago most physicians would have considered the diagnosis of typhoid fever as very doubtful; but, in addition to the typical character of the clinical symptoms, the serum test during life and the bacteriological observations made after the death of the patient render the diagnosis absolutely certain. For the notes of the case we are indebted to Mr. A. Ferguson MacCallan.

A boy, aged three years, was admitted to the hospital under the care of Dr. Cheadle on Nov. 8th, 1896, with a history of diarrhœa, vomiting, and debility. A brother and a sister of the patient had been for some time in the children's ward, suffering from typhoid fever. The date of the child's admission was probably the tenth day after the onset of the symptoms. His appearance was heavy and apathetic, the lips being dry, cracked, and bleeding. There were on the abdomen three rose-coloured papules, which faded on pressure, and there were four or five on the back. The abdomen was swollen and tympanitic, and the liver was enlarged, but the spleen did not appear to be increased in size. Previously the patient had been healthy, and no important family history could be elicited from the mother. The heart showed signs of slight enfeeblement. On examining the lungs no dulness was found, but the air entry was poor, and there were a few moist sounds and musical rhonchi heard on auscultating the back. The urine was normal. There was no marked diarrhœa, the motions being yellowish-brown in colour and of a soapy consistency. On Nov. 10th subsultus tendinum and marked carphology were observed. On the 12th the catarrhal sounds heard over the chest were slightly louder. Profuse diarrhœa began. On the 18th epistaxis and vomiting occurred. The abdomen was less distended and moved freely with respiration. On the 23rd the breath sounds heard over the chest were obscured by sibilant rhonchi and mucous râles. In the left axilla the breathing was bronchial in character. The deep cardiac dulness was a little increased to the left, and the first sound at the apex was weakened. On the 24th the patient was in a comatose condition and there was slight dyspnœa. Curds were present in the motions. The patient vomited. On the 30th the first sound at the apex of the heart was reduplicated and the second sound was accentuated; this gave a cantering rhythm to the beats. On Dec. 1st the patient was sick after food whenever given. The pulse was feeble and irregular, and he expired in the afternoon. The treatment adopted by Dr. Cheadle was directed to sustain the failing heart by stimulants and cardiac tonics; these included brandy, tincture of digitalis, and aromatic spirits of ammonia. The lung condition was treated with potassium citrate,

[1] THE LANCET, Jan. 31st, 1891.
[2] La Semaine Médicale, March, 1890.

Digitized by Google

and vinum ipecacuanhæ; the latter drug was, however, abandoned after a time as being a cardiac depressant. The diet consisted of meat teas and milk, which latterly was peptonised. On two occasions when the diarrhœa was excessive enemata of starch and opium were ordered. The case appeared to be one of profound typhoid poisoning, resulting in death from heart failure. On the twenty-first day of the disease, Nov. 19th, on applying the serum test, Mr. MacCallan found that there were loss of motility of most of the bacilli and marked clump formation. The typhoid bacillus was separated from the urine on the twenty-sixth day of the disease by Parietti's method. On the thirty-second day he suspended in 5 c.c. of water part of a two-day old stock culture of the bacillus, and to this were added two drops of blood from the patient. The fluid, previously cloudy, became clear after some hours, the bacilli having formed clumps and settled to the bottom of the tube as a flocculent, uneven mass.[1]

Necropsy.—At the post-mortem examination no ulceration of the intestine was visible, and Peyer's patches appeared to be normal. There was a slight indentation of the mucous membrane close to the ileo-cæcal valve, but this was probably accidental, since microscopical sections showed nothing abnormal. The colon was normal. The spleen was normal in size and appearance; it was opened aseptically, and cultivations on agar, gelatin, and potato were made. The culture tubes after incubation showed typical colonies of the typhoid bacillus. Mr. MacCallan examined microscopically for typhoid bacilli thirty or forty sections of the spleen, but was unable to recognise any. This was not surprising, as Gaffky says that it is sometimes necessary to examine 200 stained microscopical sections of the spleen in cases of typhoid fever before groups of bacilli can be recognised. The mesenteric glands and liver were enlarged. Before the heart was opened blood was collected from the right auricle in Pasteur pipettes and the serum test was carried out with a culture of bacilli which had been separated from the patient's urine. Loss of motility in most of the bacilli and clump formation were observed. The heart showed a slight dilatation of the left ventricle. The bronchi contained muco-pus, and there was some lobular collapse of the lung tissue. Mr. MacCallan wishes to acknowledge the valuable hints he received from Mr. Plimmer.

LEEDS GENERAL INFIRMARY.

A CASE OF PRIMARY DYSMENORRHŒA WITH EPILEPSY CURED BY DILATATION; REMARKS.

(Under the care of Dr. J. BRAITHWAITE.)

THE value of dilatation of the cervix uteri in dysmenorrhœa has been under-estimated because it has been indiscriminately applied to all forms of the disease; but, as in the following case, sometimes certainly it effects a complete and permanent cure. The removal of the concomitant epileptiform attacks is of great interest, because, although it is at the present time customary to throw doubt on reflex neuroses,[1] yet cases undoubtedly do occur, though admittedly rarely, in which severe nervous symptoms disappear on the removal of a distant source of irritation. For the notes of the case we are indebted to Dr. J. A. Clough, resident obstetric officer.

A patient, aged seventeen years, unmarried, was admitted to the infirmary complaining of severe pain at her menstrual periods with "fits." She began to menstruate at fourteen years of age, the dysmenorrhœa beginning at the commencement of menstruation. The pain usually came on just before the period, it was worst on the first day of the period, but passed off before the period ceased. The pain was so severe as to cause the patient to remain in bed. The period lasted from five to seven days, with clear intervals of from fourteen to twenty-one days, the menstruum containing clots. During the week preceding menstruation she had "fits," sometimes as many as ten or eleven occurring during that time. There were no premonitory signs, but she would fall very suddenly, losing consciousness, but with no actual convulsions. The fits lasted about ten minutes, after which she would sleep for several hours. She never passed urine or motions during these attacks. These "fits" began two and a half years ago and had continued up to the time of admission. The patient was markedly anæmic, but her general condition was apparently good. She had been treated by drugs for the dysmenorrhœa without any good result. On examination the vagina was found to be roomy, the cervix being a trifle conical, with a small os. On Jan. 11th the menstrual discharge having ceased only a few hours, the cervical canal was dilated up to No. 7 Hegar. This was done in order to allow the introduction of a laminaria tent of the largest size. No anæsthetic was used. The next day, the patient being under ether, the tent was removed and the cervical canal dilated up to No. 18 Hegar—that is, to about the size of a rather large little finger. This apparently completely cured the menstrual pain, for the mother wrote recently to say that there had been no return of it, although six months had elapsed since the dilatation. The patient has only had two fits since, both within a fortnight of the dilatation. It is somewhat doubtful whether these attacks were true epilepsy, as there was no convulsive action. The patient, however, became unconscious, and the attacks were followed by profound sleep.

Remarks by Dr. BRAITHWAITE.—As it is commonly thought, and, indeed, generally accepted as a fact, that dysmenorrhœa is only temporarily relieved by dilatation, the above case is interesting, especially as there was simultaneous recovery from menstrual epilepsy. It is usually found in the gynæcological ward that the cases which are relieved by dilatation are those in which, like the one related, the pain is at its greatest intensity on the first day of the period and ceases before the period is over. The medical treatment chiefly relied upon is the use of antipyrin just during the first few hours, followed by drachm doses of liquor ammoniæ acetatis. The typical cases for treatment by dilatation are those in which the pain is confined to the first two days of the period. The cause of the pain in these cases is either an active spasm at the os internum or a passive inability to open. During painless menstruation the os internum is open, and this opening is a vital act necessary to the painless performance of the function. For the success of dilatation it is necessary to over-dilate. Over-dilatation cannot be accomplished unless the tent is used previously. This causes a softening of the tissues, so that they yield kindly and readily. The dilatation must also be done just as a period ceases, as the tissues are then soft and already a little open. There are many cases of dysmenorrhœa which are not curable by dilatation, especially some in which probably the whole uterine muscle is in a state of colic. In these cases the pain is not confined to the first two days. There are, of course, many cases in which dilatation, however thorough, fails, but it ought to have a trial in nearly every case in which relief cannot be given by medicinal or other means, and which are severe and of long duration. It has this great advantage, that the patient is in no worse position if it fails.

Reviews and Notices of Books.

Atlas of Clinical Medicine. By BYROM BRAMWELL, M.D., F.R.C.P.Edin., F.R.S.Edin., Assistant Physician to the Edinburgh Royal Infirmary. Three vols. Edinburgh: T. and A. Constable. 1892 to 1897. Price 31*s.* 6*d.* per volume.

WITH the issue of the last instalment of the third volume of his "Atlas of Clinical Medicine" Dr. Byrom Bramwell has decided to suspend its further publication, although his stores of clinical and pathological drawings are by no means exhausted. The admirable manner in which he has carried out this enterprise deserves recognition, and for the sake of science it may be hoped that means may be found whereby the publication can be continued. It is, however, obviously out of the question that work of this high class, involving great expenditure of capital, should be left to the unaided efforts of one man. Dr. Bramwell has shown the utility and the importance of such work, and we do not hesitate to urge that its further development might well receive practical assistance at the hands of those scientific bodies who have at their disposal funds for

Digitized by Google

the encouragement of research and the propagation of scientific knowledge. These three volumes contain no fewer than 100 folio plates, many of which are highly artistic and all most faithful representations of clinical and pathological conditions.

It is not merely as an atlas that Dr. Bramwell's work should be regarded. Each volume contains detailed records of high value, reflecting the greatest credit upon the industry and ability of the author. The subjects which have been thus treated—many of them quite exhaustively—are numerous and varied. They comprise many most important contributions to the clinical and pathological study of diseases of the nervous system, such as Friedreich's ataxia, bulbar paralysis, ophthalmoplegia, alterations in the fields of vision, acute poliomyelitis, progressive muscular atrophy and the muscular dystrophies, of which latter a very valuable contribution is to be found in the final instalment of the work, including histological studies of the muscles and spinal cord from cases of pseudo-muscular hypertrophy and myopathic atrophy. Again, the subject of syphilis, illustrated by many drawings, is fully discussed in articles in the second and third volumes; and such conditions as Addison's disease, Hodgkin's disease, chlorosis, and pernicious anæmia are expounded with discrimination and judgment. Amongst other topics to be found in the several volumes are myxœdema, exophthalmic goitre, acromegaly, small-pox, measles, scrofula, and Asiatic cholera, whilst in the third volume there is a copious clinical account, with full illustration, of the effect of the thyroid treatment of certain skin diseases. Nor does this list by any means exhaust the topics which are either commented upon or illustrated, for one notable feature is the series of drawings illustrative of types of mental disease that appear in more than one volume. Having on several occasions drawn attention to the merits of the work and the praiseworthy industry of its author it is hardly necessary to dwell on them here at length, but we could not allow the opportunity to pass of expressing the hope that at no distant date a means will be found for the continuance of a publication which has acquired a distinctive position in medical literature.

The Menopause and its Disorders. (With Chapters on Menstruation.) By A. D. LEITH NAPIER, M.D.Aberd., Senior Surgeon, and Surgeon in Charge of Gynæcological Cases, and Lecturer in Clinical Surgery and on Gynæcology, General Hospital, Adelaide, &c. London: The Scientific Press, Limited. 28 and 29, Southampton-street, Strand, W.C. 1897. Price 7*s.* 6*d.* net.

IN his preface the author tells us: "Apologies are, however, unnecessary when a writer has something new to say or some new way of presenting recognised truths. The *raison d'être* of this work will be at once apparent when I state that no book dealing specially with the subject-matter here treated of has been published in Britain within the last quarter of a century. During that time the whole pathology of gynæcology has been so modified that it is now virtually new." Does Dr. Napier really mean what he says? We see that the book consists of thirteen chapters, the subjects of which appear for the most part to be the same as those met with in the numerous treatises on gynæcology in common use, except that in season and out of season the menopause is tacked on. Thus Chapter XII. is entitled "Ovarian Tumours at or after the Menopause." What reason can there be for dragging in the menopause in any useful account of ovarian tumours? They occur practically at all ages, and, so far as we can see in a work which is entitled "The Menopause and its Disorders," there is no reason to include ovarian tumours, which are certainly not disorders peculiar to the time of the menopause. The same criticism applies to the chapters on Fibroid Tumours, on Malignant Disease, and on the treatment of Vaginal and Uterine Displacements in Elderly Women. The truth is that the work is a book on the diseases of women. It is quite incorrect for the author to suggest, as we think he does, "that no book dealing specially with the subject-matter here treated of has been published in Britain within the last quarter of a century." The "subject-matter" is, for the most part, as our readers will see, matter that forms a part of every work on gynæcology. The author's standpoint as a gynæcological teacher will be sufficiently evident from the following quotation on the treatment of procidentia uteri: "In my judgment neither a plastic operation, such as colporrhaphy or [*sic*] perinæorrhaphy, nor shortening the round ligaments, nor ventrofixation, is likely to prove so curative as vaginal hysterectomy for total prolapse in elderly women. Our constant aim should ever be to cure our patients when possible; and in many of these cases this can only be done by total uterine extirpation per vaginam."

A System of Dental Surgery. By the late Sir JOHN TOMES, F.R.S. Fourth Edition. Revised and Enlarged by CHARLES S. TOMES, F.R.S. London: J. and A. Churchill. 1897. Pp. 709. Price 16*s.*

IN comparing this edition with the original published in 1859 the reader cannot fail to be impressed with the great strides that dental surgery has made during the past forty years. The present issue has been thoroughly revised and brought up to date so as to form the most reliable work that is extant in this section of medicine. In glancing through the pages it is very apparent that the changes between this and the previous edition have been somewhat drastic, and everywhere evidence is afforded that the work of editing has been carefully carried out. A chapter on the Bacteriology of the Mouth has been introduced, and the section dealing with caries has been increased and thoroughly revised, so as to embrace all the fresh knowledge that has come to light during the last ten years. In the chapter treating Materials used for Filling Teeth, Mr. Tomes has given a short but concise account of the most recent views on the properties and behaviour of amalgams, a subject of keen interest to the dental practitioner. The portion of the book dealing with manipulative proceedings is still unsatisfactory, and we feel that the value of this important text-book would be greatly enhanced by a fuller treatment of the manipulative methods. True it is that manipulative skill can only be obtained at the chair side, but much that is valuable may be gleaned from well-planned and clear diagrams of typical cases. The chapters on the Pulp and Periosteum are both interesting, but the former would be much improved by the addition of illustrations. The subject of Odontomes is very fully dealt with, and much that is new is to be found in the chapter on Absorption of the Alveoli and Pyorrhœa.

Speaking in a general way, we cannot help feeling that as a text-book for students the work would be far more readable if a little more care were taken in the arrangement of the different subjects on the basis of modern pathology. By this means we feel certain the student would gain a clearer insight into the bond which unites dental with general pathology.

Disorders of Digestion in Infancy and Childhood. By W. SOLTAU FENWICK, M.D., B.S., M.R.C.P. Lond., Physician to Out-patients at the Evelina Hospital for Sick Children. London: H. K. Lewis. 1897. Pp. 378. Price 10*s.* 6*d.*

DR. SOLTAU FENWICK, as physician to out-patients at the Evelina Hospital for Sick Children, has had ample opportunities of observing disorders of digestion in infants and

Digitized by Google

children, and in the preface of his work he informs us that it is mainly from the notes of some 5000 cases of disordered digestion which have come under his notice that the present volume has been compiled.

There is nothing strikingly original in the work, but it is an excellent compendium of our knowledge on the subject of disorders of digestion in children set forth with discrimination and clearness evidently by one who himself has a thorough knowledge of the various forms of indigestion encountered in a children's hospital. An interesting account is given of experiments made by Dr. Soltau Fenwick upon the contents of the stomachs of healthy children. He finds that in infants at the breast the milk is usually found to be curdled after a residence of from ten to fifteen minutes in the stomach. In infants fed upon cow's milk the total acidity of the gastric contents is more pronounced than in breast-fed infants, and often amounts at the end of eighty minutes to as much as 0·18 per cent. HCl, whilst in breast-fed infants it is 0·13 per cent. In infants who are fed upon farinaceous foods the total acidity of the gastric contents is invariably diminished, and may not exceed more than half the normal.

The description of the various forms of digestive disorders is well given and may be taken as a reliable guide by the practitioner and student. The subject of the diseases of children is usually neglected by students whilst at the hospitals, and, consequently, when they launch out into practice they are frequently puzzled by the many phases which gastric and intestinal troubles present, and a wrong diagnosis and treatment is frequently the result. With such a work as the one now under consideration on their shelves, such difficulties would be easily overcome, and we believe that its acquisition would be a valuable addition to their library. An appendix includes a short account of the methods employed in the chemical examination of the contents of the stomach, and certain recipes and formulæ which are useful for reference.

The book is illustrated by photo-micrographs showing the condition of the walls of the stomach and intestines in health and disease. They are admirably executed and decidedly add to the worth of the book.

LIBRARY TABLE.

The Diagnosis and Treatment of Diseases of the Rectum, Anus, and Contiguous Textures. Designed for Practitioners and Students. By S. G. GANT, M.D., Professor of the Diseases of the Rectum and Anus, University and the Woman's Medical Colleges, Kansas City, Missouri, &c. With two chapters on Cancer and Colotomy by HERBERT W. ALLINGHAM, F.R.C.S. Eng., Surgeon to the Great Northern Central Hospital, Assistant Surgeon to St. Mark's Hospital for Diseases of the Rectum, &c. Illustrated with 16 full-page chromo-lithographic plates and 115 wood engravings. Philadelphia: F. A. Davis Company. 1896 Pp. xiv.-399. Price $3 50 net.—In this volume there are many points which deserve commendation. The descriptions are satisfactory, the treatment is given very fully, and the illustrations are numerous. A great amount of care has doubtlessly been devoted to the chromo-lithographs, and many of them are excellent, but Plate VI. is decidedly useless, as it shows practically nothing and can in no sense be called artistic. The author ascribes much importance in the production of disease of the rectum to railway work, as he has found hæmorrhoids, fissure, and prolapse especially common among railway employés. As Dr. Gant has had very great opportunities of seeing patients drawn from men of this class his observations are of value. The two chapters on Cancer of the Rectum and Colotomy contributed by Mr. Herbert Allingham are, as might be expected, carefully written.

Clinical Papers on Surgical Subjects. By HERBERT W. PAGE, M.A., M.C. Cantab., F.R.C.S. Eng., Surgeon to St. Mary's Hospital and Lecturer on Surgery at its Medical School, Member of the Court of Examiners, Royal College of Surgeons of England, &c. London: Cassell and Co. 1897. 8vo, pp. x.-208. Price 5*s.*—This little volume contains ten clinical lectures delivered at St. Mary's Hospital and two other papers, and though they have all appeared previously in various journals and periodicals, they are well worth reproduction in a permanent form. They are naturally of varying degrees of interest, but there is not one which does not present the subject with which it deals in a novel and attractive form. It is difficult to say which is the most important, but the lecture dealing with a case of Fatal Pelvic Injury in a Child is certainly extremely instructive. The case is as follows. A boy, aged seven years, had been run over, and as a few drops of blood trickled from the urethra a soft catheter was passed, and a little blood was withdrawn, but no urine. The same night the child's bladder seemed to become distended as high as the umbilicus; it was thought that the distension of the bladder was due to blood clot, and as this could not be washed out per urethram a trocar and cannula were introduced above the pubes and an attempt was made to wash out the bladder from above. Subsequently urine flowed from the wound and the child died two days later. At the necropsy it was found that the pelvis had been fractured and had torn the urethra, and that the dulness above the pubes was due to an effusion of blood into the prevesical space. The trocar had not pierced the bladder. Another paper of great value is on Traumatic Rupture of the Ureter. The book is dedicated in a very appreciative spirit to the author's former house surgeons at St. Mary's Hospital.

Die Syphilis der Nase und des Halses. Von Dr. P. H. GERBER. Mit 2 Tafeln. (*Syphilis of the Nose and Throat.* By Dr. P. H. GERBER. With 2 plates.) Berlin: Verlag von S. Karger. pp. 74.—This is a reprint of a paper which appeared in the *Dermatologische Zeitschrift*, and was written at the invitation of Professor Lassar. It deals with syphilis as it affects the nose, the naso-pharyngeal space, the pharynx, and the larynx. A valuable feature is an extensive bibliography. The illustrations are good, though a little too highly coloured.

The Operations of Surgery, intended especially for the Use of those recently Appointed on a Hospital Staff and for those Preparing for the Higher Examinations. By W. H. A. JACOBSON, M.Ch. Oxon., F.R.C.S. Eng., Assistant Surgeon, Guy's Hospital; Surgeon to the Royal Hospital for Children and Women. London: J. & A. Churchill. Third edition. 1897. With 398 Illustrations. Price 34*s.*—So well known is Mr. Jacobson's work that it may seem almost superfluous to praise this new edition. The progress in operative surgery during the six years which have elapsed since the second edition appeared has been very great and has necessitated a corresponding increase in the matter contained in this treatise. The number of illustrations, 199, in the first edition has been exactly doubled, and the text has been increased to an almost equally great extent. A single volume is very much more convenient for reference than two volumes, therefore we are very glad that Mr. Jacobson has succeeded in compressing all the subject into this one volume; this has, however, only been possible by the adoption of a smaller type for part of the work, and a slightly larger page; but we fear that this will hardly be practicable in the future if surgery increases in extent as it has increased of late years. To those who knew the previous editions it will suffice to say that in the present edition the work has been brought thoroughly up to date; and to those who have not known the book in its earlier form, and who need a careful and scientific treatise on the performance of

Digitized by Google

operations, we can confidently recommend Jacobson's Operations of Surgery.

B. Bradshaw's Bathing Places and Climatic Health Resorts. London: Kegan Paul, Trench, Trübner, and Co. 1897. Price 2*s.* 6*d.*—This is a most useful book in many ways, though we do not quite see the need of the table of diseases and the places where they are most effectually treated. For instance, to call "abdominal swellings" a disease is absurd. To begin with, swelling of the abdomen is a symptom, and not always of disease. However, with this exception the book appears to be carefully drawn up, and gives a list of baths and health resorts all over the world, even to the little known but valuable springs in the Caucasus. The suggestions at the beginning are admirable and to be pondered upon, though we think that it is at last beginning to dawn upon the average Briton (1) that the Continent was not entirely created for his special use, and (2) that occasionally it is possible that he may come across "a foreigner" who is as good a gentleman as himself, or even better.

JOURNALS AND REVIEWS.

Science Progress. July, 1897.—This quarterly issue is a decidedly all-round interesting number. From the medical point of view perhaps the paper on "The Venoms of the Toad and Salamander," by Dr. Richard T. Hewlett, merits the first place in our attention. We deal with it in another column. The important contribution by Mr. C. A. Barber, M.A., on "The Diseases of the Sugar-cane" is continued. Finally, in the longest paper in this number, Mr. Minchin, M.A., discourses upon "The Position of Sponges in the Animal Kingdom." He inclines to the view that they are true metazoa.

Caledonian Medical Journal.—Dr. Alastair MacGregor, of Shepley, Huddersfield, publishes the first portion of a remarkable paper on Second Sight, the continuation of which is promised for the October number. He gives details of nine cases, in five of which either himself, himself together with his sister, his father (a clergyman in Skye), or his grandfather (also a clergyman) were immediately concerned. Two of these nine events were instances of presentiment only; all the others were accompanied by surprising audible or visible manifestations, and one of them may be quoted as a typical example. Many years ago Dr. MacGregor and his sister were on a visit to an invalid clergyman near Inverness. One evening after sunset, in the month of October, the two visitors were examining photographs in the drawing-room with the lady of the house, the husband being in bed, and his nephew being expected to arrive from a distance about 8 P.M. About 6 P.M. the three persons in the drawing-room all at once "heard the sudden sound of a trap driving quickly up the avenue, followed speedily by the crunching of wheels on the gravel at the front door, the grating noise of a brake being applied—in short, all the usual sounds attendant on the drawing-up of a conveyance." Dr. MacGregor rushed to the front door to welcome his friend, and continues: "To my surprise there were no signs of a trap being there; the moon was shining brightly, and everything was still. I had just re-entered the hall, feeling very crestfallen, when I heard a piercing shriek in the dining-room, and out rushed Mrs. —— saying that Mr. —— had just died." The weirdness and the speedy realisation of Dr. MacGregor's various "warnings" are not excelled by the vision of Theoclymenus, as related in the twentieth book of the Odyssey. This personage, who had a reputation as a seer, on a festive occasion told the self-complacent suitors of Penelope that their heads and faces and knees appeared to him to be veiled in darkness, and their cheeks to be wet with tears, the walls of the apartment were splashed with blood, and the fore-court of the house and the hall were filled with spectres on their way to the under-world. He was laughed at for his speech, but Ulysses had already returned in disguise, and in a day or two put all the suitors to death. Another interesting article in the current number of this journal is entitled "Medical Heroes of the 'Forty-five," by Dr. W. A. Macnaughton, medical officer of health of Kincardineshire.

Analytical Records
FROM
THE LANCET LABORATORY.

BALLARDVALE LITHIA-WATER.

(AGENTS: INGRAM AND ROYLE, 26, UPPER THAMES-STREET, E.C.)

LITHIUM SALTS seldom occur in natural mineral waters unassociated with other salts which may detract from the medicinal value of the water in the treatment of gouty disorders. Assuming that the specimen of Ballardvale water recently submitted to us is a naturally occurring product its composition is certainly remarkable. Thus, of the total quantity of mineral water (15·4 grains per gallon) no less than 13 grains, or 84 per cent., consisted of carbonate of lithium. The water is consequently very soft to the taste, and is quite free from mineral salts such as the sulphates of lime, which are undesirable for persons who suffer from gout. The common salt amounted to only 0·7 grain per gallon. Further examination showed that the water was of admirable organic purity. It is well known that draughts of pure water copiously taken are of advantage in uric acid diathesis in irrigating the urinary passages. When it happens that the water so employed contains lithium in the form of alkaline salts, as in the case of the Ballardvale water, there can be little doubt that an important advantage in treatment is thus gained. The water can be obtained either plain or aerated.

COPENHAGEN BEERS (GAMLE CARLSBERG).

(IMPORTERS: F. BAGGER AND CO., 3 AND 4, GREAT WINCHESTER-STREET, E.C.)

Since the discovery by Dr. Hansen, of the Carlsberg Laboratory, Copenhagen, that the various diseases of beer were caused by certain species of yeast, brewers have been enabled to place upon the market a much more satisfactory and, moreover, a more uniform product. Instead of employing yeast without regard to its specific character as to whether it contains mixed forms or not a pure culture is separated which produces a beer of always the same quality and character. The same "race" of yeast is always employed. This, together with the fact that the fermentation is conducted slowly and at a low temperature (the yeast growing from the bottom upwards rather than on the surface, as in the case of English brewing) is quite sufficient to account for the excellent and uniform condition of beers produced on the Continent. Types of these are admirably illustrated in some samples we have recently received from the Copenhagen Laboratory. The results of analysis were as follows:—Pilsener: extractives, 4·48 per cent.; mineral matter, 0·15 per cent., alcohol, by weight 3·41 per cent., by volume 4·27 per cent., equal to proof spirit, 7·49 per cent. Lager beer: extractives, 5·16 per cent.; mineral matter, 0·22 per cent.; alcohol, by weight 4·0 per cent., by volume 5·0 per cent.; equal to proof spirit, 8·77 per cent. Carlsberg beer: extractives, 6·11 per cent.; mineral matter, 0·35 per cent.; alcohol, by weight 4·0 per cent., by volume 5·0 per cent., equal to proof spirit

Digitized by Google

8·77 per cent. Imperial stout: extractives, 9·43 per cent.; mineral matter, 0·35 per cent.; alcohol, by weight 4·62 per cent., by volume 5·78 per cent., equal to proof spirit 10·13 per cent. In not one of these specimens was any preservative found, while there was no evidence of malt or hop substitutes being present. They were all in good, sound condition, possessing that peculiar taste and character which beers fermented at a low temperature evince. Again, while the amount of alcohol was comparatively small the beers contain a maximum amount of malt extractives, and the taste is decidedly less bitter than ordinary English ale. As we have pointed out before, the fact that a smaller quantity of hops is employed, coupled with the smaller percentage of alcohol, affords some explanation that the so-called lager beers are lighter and less stupefying than the mild and bitter ales brewed in this country.

FROMMES EXTRACT.

(FROMMES EXTRACT CO., 61½, FORE-STREET, E.C.)

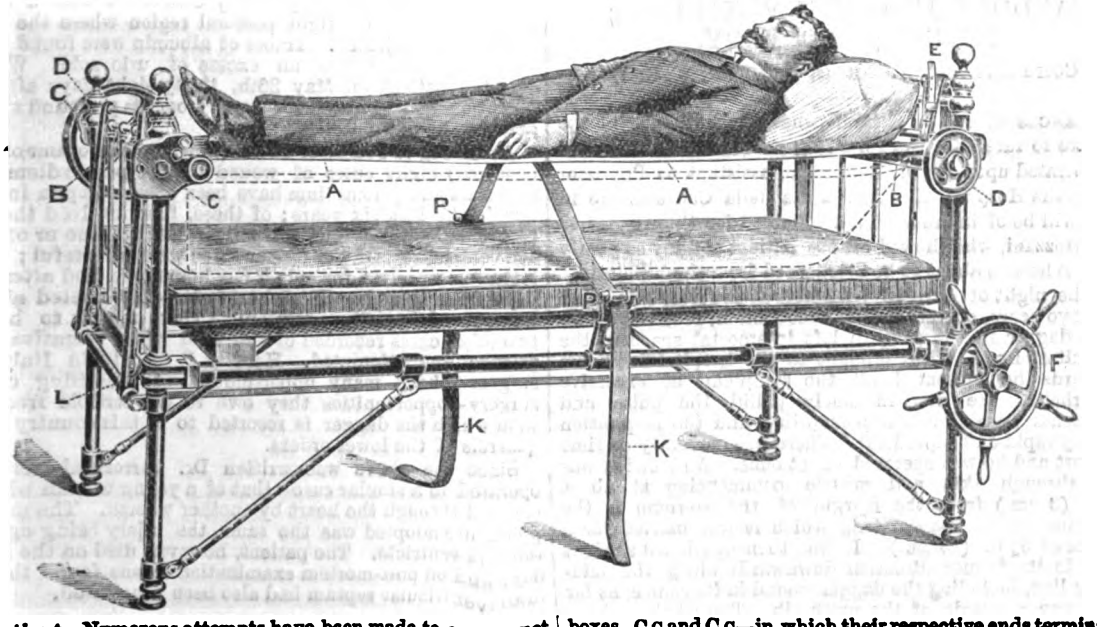
This extract is of purely vegetable origin, and, according to the results of our own analysis, presents the composition of a complete food (*vide* THE LANCET, Dec. 4th, 1896). In appearance it is like ordinary meat extract, and may be used in a similar way. Since we published our analysis of the extract we have received further preparations, into the composition of which this vegetable extract largely enters. They are—(1) soup tablets, (2) condensed milk, and (3) various biscuits. The initial food value of the articles just indicated are undoubtedly enhanced by this addition. Another preparation of the extract contains a less proportion of fat, and in a great number of cases we think this modification would constitute an improvement in regard to digestibility. The extract gives distinct evidence of peptones. As is well known, there are distinct merits belonging to vegetable food which are absent in animal food, and *vice versâ*. This extract, therefore, should afford an important nourishing adjunct to the dietary.

LEMON SQUASH AND LIME JUICE CORDIAL, &c.

(WALTER SCOTT AND CO., ROCK FERRY, CHESHIRE.)

We found no evidence during the course of our examination of these preparations that they are not, as stated, "prepared from the finest selected fruit." It is obvious that if unsound fruit had been employed the flavour of the resulting cordial or liquid would be unsatisfactory. The samples of lime juice cordial and lemon squash possessed a good fragrant flavour characteristic of the respective fruits from which they are made, but in our opinion they are too syrupy and sweet. The acidity of the former, calculated as crystallised citric acid, amounted to 1·89 per cent., and of the latter to 2·17 per cent. In the raspberry and lemon preparation as well as in the black currant liquid we could trace no evidence of foreign colouring matters. All the preparations proved to be free from metallic contamination, but each one is somewhat heavily preserved with salicylic acid.

SCOTCH WHISKY (THE BUCHANAN BLEND).



(JAMES BUCHANAN AND CO., GLASGOW, LEITH, AND LONDON.)

Our analysis shows this to be a remarkably pure spirit, and therefore well adapted for medicinally dietetic purposes. It contains a very small proportion of extractive matters, while the acidity is practically *nil*. The actual results of analysis were as follows: Alcohol, by weight 38·78 per cent., by volume 46·02 per cent., equal to proof spirit 80·64 per cent.; extractives, 0·21 per cent.; mineral matter, *nil*; acidity reckoned as acetic acid, 0·027 per cent. The spirit, whilst free from injurious and crude products, possesses a delicate and smooth flavour, owing partly to skill in blending and partly to the maturing effects of storage for some years in wood.

New Inventions.

THE "FACILE PRINCEPS" BEDSTEAD.

A BED as ordinarily constructed is not an ideal arrangement even for the healthy, and when used by the sick and suffering is often a source of inconvenience to practitioner, nurse, and patient. Numerous attempts have been made to construct a bed which should answer the manifold requirements of the sick-room, but the majority have been more or less necessarily complicated and expensive. A cheap and simple couch for the sick has yet to be invented, but in the meantime the bed illustrated below merits attention. Simply stated, the patient is put upon a sheet divided through its entire length with its edges over the central axis of the bed overlapping. The top and bottom ends of this divided sheet are affixed to rollers, which are made to ascend and descend on the four pillars of the bedstead. The following describes the process in detail. Two iron rollers, B B, are attached by means of four hollow

boxes, C C and C C—in which their respective ends terminate—to the four pillars of the bedstead. The sheet upon which the patient is lying, A A, is attached to the rollers, B B, and

Digitized by Google

can be tightened or loosened by means of the small wheels, D D. This sheet is divided down the centre from head to foot, with the smooth edges overlapping from two to six inches. The webbing E passes upwards at one end from the sheet roller, over the top rail of the bedstead, down to and round an iron drum, L, to which it is fixed. A second piece of webbing passes from this drum underneath the bed to a similar one affixed to the other end of the bedstead, and upwards to the top rail of the bedstead, then the end is attached to the sheet roller at that end; so that the two rollers with sheet attached are raised simultaneously by turning the large wheel F, which is fitted to the iron drum at one end, and also controlled by a ratchet. When necessary to raise the patient, as in the illustration, either to change the sheets or for any other purpose, the sheet is tightened until it becomes almost rigid, and the nurse turning the wheel F, the patient is raised on it with an easy and almost imperceptible motion as the brass wheels of the rollers glide up the pillars of the bedstead. It is fixed by means of a pawl and ratchet at any height between the mattress and the top of the bedstead. The nurse can then withdraw the mattress and return it, placing upon it a clean sheet divided in the same manner as the one upon which the patient is raised, this being lowered until about an inch above the clean one. Then the bands K K, passing round the anti-friction rollers P P, are drawn upwards and towards the centre of the bed, over the patient, thus drawing the two divisions of the sheet apart and leaving the patient upon the clean one beneath. Either end of the sheet can be raised independently of the opposite end, if so desired, in order that the patient may be placed in an inclined position. There is also an arrangement by which a semi-sitting position may be obtained or the position naturally assumed on a double inclined plane. If required an operating table can be attached to the bed and the patient lowered upon it, thus obviating the removal of the patient from the bed. For giving the bath in typhoid fever the bed seems to offer great facility, and the ease with which the bed pan can be used recommends it to both nurse and patient. Another advantage is that in hot weather or in hot climates the patient can be raised frequently and a current of air allowed to pass underneath the bedding. The bed has been designed by Mrs. William Douglas with a view to economising labour whilst giving a maximum of comfort to the patient, and this we think she has succeeded in doing. The bed can be obtained from Messrs. Maw, Son, and Thompson, 7 to 12, Aldersgate-street, E.C.

PENETRATING WOUND OF THE PERICARDIUM AND LEFT VENTRICLE; SUTURE; RECOVERY.

(COMMUNICATED BY DR. G. SANDISON BROCK.)

INSTANCES of recovery from penetrating wounds of the heart are so rare that the following account of a successful case operated upon by Dr. Parrozzani, assistant to Professor Tassi at the Hospital of Santa Maria della Consolazione in Rome, will be of interest. I am indebted for these notes to Dr. Parrozzani, who showed me the patient already so nearly well that he was about to be discharged from the hospital.

On the night of April 18th, a porter at the river-side, aged thirty-two years, of very robust constitution, received a stab from a dagger in the seventh left intercostal space in the mid-axillary line. When brought to the hospital five hours afterwards he presented all the symptoms of excessive hæmorrhage. He was extremely pallid, the pulse and heart beats were almost imperceptible, and the respiration was very rapid and superficial. There was evidently no time to be lost and he was operated on at once. An incision was made through skin and muscle commencing at about 1¼ in. (3 cm.) from the margin of the sternum in the fourth intercostal space, along which it was carried for a distance of 5½ in. (14 cm.). It was then continued at right angles to its former direction downwards along the mid-axillary line, including the dagger wound in its course, as far as the upper margin of the ninth rib. The whole incision had thus the shape of the letter L inverted. The pleura was next incised at the level of the fourth intercostal space in the horizontal line of the inverted L, and the fifth, sixth, seventh, and eighth ribs, with the attached pleura, cut through in the vertical line. A triangular-shaped door or shutter, to which the costal cartilages acted as a hinge, was thus formed. Such a large opening was deemed desirable for fear of any wound of the diaphragm or abdominal viscera. On reflecting the shutter, the pleural cavity was found filled with blood, and the pericardium presented a solution of its continuity 1 in. (2½ cm.) in length, from which at regular intervals issued a small jet of blood. The opening in the pericardium having been enlarged to nearly 2½ in. (6 cm.), the cavity was freed of the small quantity of blood it contained. The blood had not accumulated in the pericardial sac in any considerable quantity owing to the fact that the wound in the latter, being at its most dependent part near the apex of the heart, had allowed the blood to escape readily into the pleural cavity. This was a fortunate circumstance, since the usual cause of death in these cases—viz., the fatal pressure exercised upon the heart by the blood accumulating in the sac around it—was here absent. The apex of the heart presented a wound about ¾ inch (2 cm.) in length, from which the blood spurted in small jets at every beat of the organ. The pulsations of the heart had become so extremely feeble that it seemed as if they were about to stop altogether. Introducing the little finger of the left hand into the wound, Dr. Parrozzani found that it passed into the left ventricle obliquely, but quite freely from the apex towards the base. The inserted finger served the double purpose of checking the hæmorrhage and of fixing the apex of the heart so that the wound could more easily be secured. A large curved needle armed with No. 2 silk was now passed deeply through the whole thickness of the myocardium, but without touching the endocardium, the little finger being withdrawn from the wound and the thread rapidly knotted. The entrance of the needle into the myocardium caused the heart to throb vigorously, and the withdrawal of the finger was followed by a gush of blood completely flooding and obscuring the field of operation. The wound was, however, effectually closed by three more stitches, the blood-clots cleared out of both pericardial and pleural sacs, and the "shutter" in the chest wall finally closed by deep and superficial sutures. The operation lasted an hour and a quarter. No chloroform was used, but twelve subcutaneous injections of ether and five of camphorated oil, and a few of caffeine were administered. A saline solution (1500 grammes) was introduced by hypodermoclysis, and thorough auto-infusion (by means of Esmarch's bandages), was practised. One hour after the operation the pulse became quite perceptible. The wound healed by first intention, and no complication in myocardium or pericardium arose during convalescence. The temperature on one occasion rose to 102° F., but this was probably connected with a slough which formed in the right pectoral region where the saline solution was injected. Traces of albumin were found in the urine and there was an excess of uric acid. When I saw the patient on May 26th, thirty-eight days after the operation, he had nearly recovered from his profound anæmia and said he felt quite well.

According to Professor Tassi[1] (in whose clinic four of them occurred) eight cases of wound of the pericardium or of the heart and pericardium have been operated upon in Rome during the last six years; of these, four involved the pericardium alone and four the pericardium and one or other of the ventricles. Of the former three were successful; of the latter two survived for only a few hours, one died after eight days from anæmia, while the fourth—that related above—has proved entirely successful. There appear to be only two other cases recorded of the kind where operative interference was attempted. Happily it is only in Italy that surgeons have many opportunities of practising cardiac surgery—opportunities they owe to the terrible frequency with which the dagger is resorted to in this country in the quarrels of the lower orders.

Since the above was written Dr. Parrozzani has again operated in a similar case—that of a young woman who was stabbed through the heart by another woman. The mode of procedure adopted was the same, the injury being again in the left ventricle. The patient, however, died on the second day, and on post-mortem examination it was found that the inter-ventricular septum had also been penetrated.

THE LANCET.

LONDON: SATURDAY, JULY 31, 1897.

THE medical officers of health of Scotland are to be congratulated on the very satisfactory alterations which have now been made in the Public Health (Scotland) Bill. The whole profession, indeed, has a right to congratulate itself, and the public not less than the profession.

It happens that an Act applying to the burghs of Scotland, though not to rural districts — the Burgh Police (Scotland) Act of 1892—contains an extraordinary provision that the sanitary inspector (and *not* the medical officer) shall "superintend and enforce the sanitary provisions" of the Public Health Acts. This unique enactment appears to have had its origin in some vague notion that if a medical officer of health in a burgh were engaged in private practice he would be likely to be less independent than a sanitary inspector wholly occupied in the service of the local body. While we are strongly of opinion that it is in the interests of public health that the districts supervised by medical officers of health should be so large as to debar such officers from general practice, yet it is absurd to say that a whilom joiner or plumber who is appointed to be sanitary inspector and fire-master and road surveyor in a petty burgh at a salary of £70 or £80 a year, and whose main anxiety is to get other £10 added, is likely to be more independent in his work than a medical officer who has an income, say, of £500 a year independently of the burgh commissioners. Anyhow, nothing more objectionable could well be conceived than this provision in Section 75 of the Burgh Police Act, which slipped through unchallenged at the fag end of the Session of 1892, and which hoisted the sanitary inspector into the position of "superintending and enforcing the sanitary provisions" of the Public Health Acts in burghs. It was most important, therefore, as we pointed out in a previous article,[1] that the passing of a new Public Health (Scotland) Bill should be taken advantage of to attack Section 75 of the Burgh Police (Scotland) Act. The attack was made from two points. In the first place, several members of Parliament gave notice of motion that the medical officer of health of every local authority, burghal and rural, should in future be responsible for the enforcement of the provisions of the Act, and in some of these notices the very words above quoted from the Burgh Police Act were copied, with the substitution of medical officer for sanitary inspector as the responsible official. In the second place, other Members of Parliament set down amendments providing for what would amount in practice to the repeal of the objectionable part of the Burgh Police Act. It should be explained here that last year when the Bill was in the Upper House Lord BALFOUR of BURLEIGH, the Secretary of State for Scotland, granted a useful concession to medical officers of health. Since the formation of county councils about seven years ago several of these bodies have learned by experience that a public health department does require a responsible head, and that that head ought to be the medical officer of health. But on framing by-laws to give effect to this conclusion they were met by the difficulty that, excepting in one notable instance, the central authority refused its sanction on the ground that the present Public Health (Scotland) Act does not provide for the subordination of the sanitary staff to the medical officer of health. Lord BALFOUR'S policy has been, not to make the medical officer of health supreme in his department, but to allow every local authority to do so if it sees fit. He has apparently had in view the possibility of medical officers of health being incompetent, or inactive, or over-active. To give effect to his policy he inserted a provision that local authorities should "regulate the duties and relations" of the two classes of officials, and that this power should refer, not only to future appointments, but to appointments already made. It was in connexion with this provision that the second attack was made on the Burgh Police Act, the attack taking the form of a motion that the regulation of duties and relations of medical officers of health and sanitary inspectors should take effect, "notwithstanding anything contained in Sections 75, 76, and 77 of the Burgh Police (Scotland) Act, 1892"—that is, notwithstanding the enactment that in burghs sanitary inspectors were to "superintend and enforce" the sanitary provisions of the Public Health Acts. There were therefore before the House two sets of amendments, the first declaring it to be the duty of the medical officer of health to "superintend and enforce," and the second declaring that the new Act should override the Burgh Police Act in so far as that Act had provided that the sanitary inspector should be the officer appointed to "superintend and enforce" the sanitary sections of the Public Health Acts. The position created by these two sets of amendments was that if, in view of Lord BALFOUR'S policy, as above indicated, the Government refused to accept the first, they could hardly refuse to accept the second, for every argument advanced against the first would be an argument in favour of the second. This was what actually happened in the debate. The first amendment was proposed in an able speech by Captain SINCLAIR, who had obtained a knowledge of public health administration in the London County Council, and who had no hesitation in urging that in the district of every local authority the medical officer of health should be made the responsible head of the health department. The LORD ADVOCATE declared that the acceptance of Captain SINCLAIR'S amendment would place the medical officer of health above the local authority itself. The statement was an amazingly strong one, seeing that an Act passed by a Conservative Government has since 1892 placed the sanitary inspector in burghs in exactly the same position as Captain SINCLAIR'S amendment proposed that the medical officer of health should now be placed. But the virtue of the LORD ADVOCATE'S statement consisted in its strength, so far as the second amendment was concerned, and the first amendment being defeated (though it received an unlooked-for

[1] THE LANCET, May 8th, 1897, p. 1282.

Digitized by Google

amount of support), there was no choice but to accept the second. It is no doubt conceivable that this latter amendment might have been accepted independently of the introduction of the former, but in a matter so important nothing could be left to chance.

Sir CHARLES CAMERON, in the Grand Committee, fought hard against a most retrograde proposal to relax the requirement of the present law that future medical officerships of health shall be conferred only on holders of qualifications in public health. The proposal was that in the case of burghs a public health diploma might be dispensed with "with the express consent of the Local Government Board." This was carried in committee by a small majority, and there seemed little likelihood of the decision being reversed on the report stage; but the unexpected happened, and the honourable Member is to be congratulated on his success in restoring the original requirement.

Further, in Clause 15, an awkward slip had been made with regard to the power of medical officers of health to perform any of the duties of sanitary inspectors. In the interests of sparsely populated highland counties Mr. CALDWELL had proposed that every medical officer of health might, whenever he saw fit, perform any duty which a sanitary inspector would be empowered by the Act to perform. This was objected to as amounting to an insidious attempt to place the medical officer of health at the head of the sanitary staff, and a modification was accepted that a medical officer of health might perform such duties when "authorised" by the local authority. By an unfortunate error the word "required" was set down instead of "authorised," and in the Report stage Mr. CALDWELL got this remedied.

Much anxiety was felt as to the fate of Clauses 22 and 36, in which it was proposed that the sanitary inspector should have conferred on him the statutory right to certify nuisances as a basis for legal prosecutions. Quite a number of members—Sir WALTER FOSTER, Colonel DENNY, Dr. FARQUHARSON, and others—had given notice of amendments to omit the sanitary inspector from both clauses, and the LORD ADVOCATE himself had set down such an amendment as regards Clause 36, which deals with offensive trades. The fight, therefore, was waged entirely round Clause 22, and here Sir WILLIAM PRIESTLEY did excellent service. His amendment differed from the others in proposing to omit both medical officer of health and sanitary inspector, so that the grounds for initiation of proceedings would be left entirely to the local authority. As it turned out, this was a judicious compromise. The LORD ADVOCATE had been anxious to meet the difficulty by altering the clause so that proceedings might be initiated either on a certificate by the medical officer of health or after a report by the sanitary inspector. This was no doubt an improvement, in so far as the Bill would no longer have assumed the competence of the sanitary inspector to "certify" nuisances, but only to "report" regarding them. There would still, however, have remained on the face of the Bill an invitation to local authorities to take proceedings at law as to danger or injury to health based on a sanitary inspector's report, and without reference to, or consultation with, the medical officer of health. Sir WILLIAM PRIESTLEY therefore adhered to his amendment, and the LORD ADVOCATE, after listening to both lay and medical opinions, frankly yielded, and withdrew his own proposal. On other clauses in the Bill alterations were made on similar lines.

The success which has been met with in the report stage is most gratifying. The support which was received, not only from medical Members of Parliament such as Sir WALTER FOSTER, Sir WILLIAM PRIESTLEY, Sir CHARLES CAMERON, Dr. FARQUHARSON, and Dr. CLARK, but also from lay members interested in public health like Captain SINCLAIR, Colonel DENNY, Mr. BRYCE, and Mr. J. A. CAMPBELL, deserves every acknowledgement. The LORD ADVOCATE'S attitude, too, at least in the later stages of the discussion, was much more satisfactory than in Committee. And as regards Mr. CALDWELL there is no doubt, we think, that he was anxious to rectify the blunders which he had unwittingly committed in Clauses 22 and 36. His acquiescence in the reversal of his amendment on Clause 36 is noteworthy, and so also is his support of Sir WILLIAM PRIESTLEY'S amendment on Clause 22, and the vote which he both gave and "voiced" with regard to Clause 45. At this period of the session it is hardly likely that anything which has been gained in the Commons will be lost in the Lords, but even there vigilance will be necessary.

In the course of this discussion we have held that the interests of the public and those of the medical profession are identical. The public, however, could not be expected to be so much alive to the threatened danger, and the duty of informing Parliament has therefore fallen mainly upon the profession. The essential unity of medicine has been pleasantly shown in the ungrudging fashion in which the General Medical Council and the general practitioners have coöperated with the health officers in this work of educating Parliament. Medical societies and branches of the British Medical Association have vied in activity with the organisations specially representative of sanitary science. This is as it ought to be, and we doubt not that it will so remain. It would be an evil day alike for preventive medicine and for curative medicine if they became seriously dissociated from each other.

THE new Bill dealing with the re-constitution of the University of London has been introduced into the House of Lords and has passed practically without debate. On the second reading the Duke of DEVONSHIRE, as Lord President of the Council, stated that after prolonged negotiations with the various parties interested, the present Bill had been introduced as a workable compromise. Lord KIMBERLEY as a Fellow of the University of London, gave it his blessing. Its career in the House of Lords has been a very smooth one. It is in the House of Commons that difficulties will probably have to be met and overcome. We hope that the Government is really in earnest and intends to force the Bill through during the present session. We cannot pretend that the Bill is an ideal one or that it represents our views that a teaching university and an Imperial examining board should be kept apart. But if they must run together in double harness

Digitized by Google

the arrangements in the Bill seem to us to be very well adapted to the purpose intended. Mr. COZENS-HARDY, as chairman of the Committee of Graduates generally approving the schemes of the COWPER Commission, asks that the scheme shall be supported, and this is re-echoed by Dr. T. B. NAPIER and Mr. J. B. BENSON, the chairman and secretary of the Gresham Amendment Committee. Mr. E. H. BUSK, as chairman of Convocation, also strongly recommends his fellow-graduates to support it.

There is no question that if London is to have a real university it must be established on some such lines as are suggested in this compromise. The idea of a teaching university on the Scottish or German plan is beyond the domain of practical politics whilst the present University and its Imperial examining board are in possession of the field. This Bill varies in some important points from those introduced in 1895 and 1896. The Commissioners have no longer a free hand in framing statutes and regulations provided these are in general accordance with the scheme of the report of the COWPER Commission, but a number of important details are placed in the Schedule of the Bill with which they cannot interfere. In Part I. of the Schedule the constitution of the Senate is laid down, and it is not only to be the supreme governing body but the Executive of the University. Three standing committees will have advisory powers only. First, the Academic Council consisting of the sixteen members of the Senate appointed by the Faculties, the three *ex-officio* members, and a senator or senators selected by the Senate to make the number of members up to twenty, this body forming the committee for internal students—i.e., students who have matriculated at the University and who are pursuing a course of study approved by the University in a school or schools of the University or under one or more of the recognised teachers of the University. Secondly, the Council for External Students, consisting of the sixteen members of the Senate appointed by Convocation—other than the Chairman of Convocation—the three *ex officio* members, and senators elected by the Senate to make up the number of members to twenty-eight. Thirdly, a Standing Board to promote the extension of University teaching to consist of the three *ex-officio* members and senators elected by the Senate. The *ex-officio* members of all these three committees are the Chancellor, the Vice-Chancellor, and the Chairman of Convocation. The constitution of Faculties, Boards of Studies, and the standard of the examination for the degrees as being equal for internal and external students are also authoritatively laid down. The certificates and diplomas will state whether the candidate has passed as an internal or external student. Inasmuch as every medical student must necessarily be an internal student, his position is not altered, but the change is of great importance in the Faculties of Arts, Law, and Science.

There can be no doubt that the opponents of the COWPER scheme have gained very substantial advantages in the present Bill. They have secured eighteen out of fifty-six members of the Senate instead of one-seventh; they have prevented the Academic Council having any executive functions, and they have also secured a position for the Council for the external students coördinate with that of the Academic Council for internal students. The constitution of the Statutory Commission could hardly be improved. Lord DAVEY (chairman) the Lord Bishop of LONDON, Lord LISTER, Sir WILLIAM ROBERTS, Sir OWEN ROBERTS, Professor JEBB, and Mr. BUSK (the chairman of Convocation) are so thoroughly versed in the various phases of the question of higher and technical education in London that it is almost needless to say that their names have been received with general approval.

A GREAT deal of ill-feeling has been engendered, and some scandal has been created, by the action which the Vestry of St. George's, Southwark, have taken with regard to the annual report of their medical officer of health. For some reason or other Dr. WALDO'S reports do not find favour with certain members of the vestry, and it is highly probable that this is, in part, due to the fact that Dr. WALDO does not commend the vestry for things which they ought to do, but have left undone. Under any circumstances the vestry, or one of their committees, proposed to revise the annual report and to print only so much of it as seemed good to them. According to the Order of the Local Government Board, dated Dec. 8th, 1891, every metropolitan medical officer of health is required to make an annual report comprising a summary of the action taken and of advice given for preventing the spread of disease, and comprising also an account of the general sanitary condition of the district at the date to which the report refers. There is also to be an account of inspections made, of conditions that are injurious to health, and of proceedings taken or advised as to numerous matters, including offensive trades, dairies, factories, workshops, &c., and this report must be sent by the medical officer of health to the Local Government Board. It will be obvious to every right-minded person that it is essential that this report shall be that of the medical officer of health, and not a report that has been tampered with and amended. This is as necessary in the interests of the public as it is for the purposes of the Local Government Board, for after all it is primarily the public interests and not those of the vestry that are in question in this annual report. It has, therefore, always been held that this annual report must not be altered by any person other than the medical officer of health himself; and it is the proposal to modify the reports of Dr. WALDO, or to subject the issue of them to a revising committee of the vestry, that has brought about the discreditable proceedings which have for some time past been in progress in Southwark.

At this stage of our remarks we would point out that directly any indication of supervision of annual or other reports by a health officer becomes apparent it will be policy on the part of that officer to confine his reports somewhat strictly to the instructions issued by the Local Government Board in the matter; for we are free to admit that we have in certain cases seen discussions and theses embodied in annual reports, of which a critical authority would have a right to say that they formed no proper part of such a document. And, further, we have seen annual reports of becoming dimensions padded out into a volume of quite undue bulk by a mass of appendices, some parts, at least, of which had no direct or even general bearing on the

Digitized by Google

sanitary condition or administration of the district in question during the year under review. We do not refer to the Southwark case in this respect; for the vestry, finding that they have no power to edit Dr. WALDO'S reports according to their own liking, have adopted another method of preventing the publicity of this document: they have only printed sixty copies. One of these has presumably gone to the Local Government Board, and the remaining fifty-nine seem to be in the hands of members of the vestry and their friends, the consequence being that we have as yet not seen this report which has caused so much trouble in Southwark.

We do not propose here to discuss the legality of thus limiting the issue of the report, but we must point out to the ratepayers of St. George's, Southwark, that it is their place to see that the annual reports of their medical officer of health are not hidden away in this manner. The Government of this country has required the appointment of medical officers of health for the protection, and in the interests, of the public, and especially of that portion of the community which is least able to defend itself, and to demand that it shall be provided with means of decent and wholesome living. If the vestry have nothing to hide, in so far as they themselves are concerned, or if they think Dr. WALDO'S report contains matter which should not be embodied in such a document, then the proper course would be to print so much of it as constitutes the report, to circulate it widely, and to appeal to public opinion as to its being a proper and honest report. But by taking the step they have adopted they have gone far to convince many that the report contains matter which does properly find a place there, but which they, in their own individual interests, do not want to have exposed to the light of day and to the intelligent apprehension of their constituents. Whatever, therefore, be the reason of this misguided and puerile action, the members of the vestry themselves alone come under suspicion; and for that reason they had better abandon the unfortunate position into which they have drifted.

OUR Dublin Correspondent informs us that 124 cases of beri-beri have occurred in the course of a fresh outbreak of the disease in the Richmond Asylum, Dublin, and it is impossible to learn the serious nature of this recrudescence without anxiety. The reappearance in successive years of so grave and fatal an oriental malady in one of our national domestic institutions is a matter that deserves the most careful consideration, and one that demands the adoption with stringency of all such measures as experience has shown to be most likely to lead to good results.

The cause of beri-beri is unknown, for though all things point to a specific germ the exact organism has not yet been satisfactorily determined. The white staphylococcus of PEKELHARING and WINKLER, it is true, fulfils several of KOCH'S well-known postulates, which have to be satisfied by any germ claiming the honours of specificity, but the whole story has not yet been told. This is well shown by Dr. W. K. HUNTER in a contribution to our knowledge of the etiology of the subject, which will be found on page 240 of this issue, and which contains in addition to a clear account of some careful experiments an interesting *résumé* of the work of previous investigators. But although the discovery of a specific germ has yet to be made, we know perfectly well that where beri-beri has once broken out it is apt to remain, and also that overcrowding and bad ventilation are conditions which greatly favour its spread. In those Eastern countries where it is common it is a dweller on the threshold of gaols, and abides with communities where individuals live closely crowded together in defiance of health and decency. In addition to bad ventilation and overcrowding, it is also recognised that insufficient diet encourages the development of the disease. But it should be borne in mind that these conditions foster, but do not generate, beri-beri. The morbid entity which causes it must be imported into the locality in which the vicious environment prevails, an environment which is eminently favourable to the development of many other epidemic diseases. The first question, therefore, that must suggest itself to those seeking to control the outbreak in the Richmond Asylum is whether there is any evidence to associate its occurrence with any source of infection from countries where beri-beri is endemic; and, as far as we can learn, no connexion seems to have been traced. That the disease was originally brought to the asylum by patients or in food or clothing arriving from some Eastern country seems an inevitable conclusion, and of these infected food seems to us the more probable, for beri-beri is not contagious from person to person. But the infection once brought to the asylum we find that all the conditions which go to form a favourable soil for the development and persistence of the disease are present. The overcrowding is undoubted and the want of ventilation must follow. Sir THORNLEY STOKER, in a communication to a new Dublin paper, the *Daily Nation*, is quoted as saying that "not only is the whole institution overcrowded far beyond its normal accommodation, but that even the new wooden male building is not fit to receive more than half the number at present occupying it. Its two dormitories are at present occupied by 100 patients, although not suited to give sanitary accommodation to more than 50. The female permanent hospital contains as many as sixty-three patients, who have an average of 451·968 cubic feet of space each." Sir THORNLEY STOKER points out that the proper number of persons to be accommodated in such a space would be twenty-five only, and adds that in this wing a corridor is being used as a dormitory, and that the floor space is so over-occupied that of the sixty-three patients seventeen sleep on mattresses placed on the floor. We may take it, therefore, that the presence of the two factors universally allowed to perpetuate and foster beri-beri is established in the Richmond Asylum. Again, the conditions of asylum life altogether, apart from overcrowding and in the presence of perfect hygiene, are not unfavourable to the spread of a disease of low nervous type. With a vicious overcrowding the spread of the disease becomes inevitable when once it has been introduced. The persistency with which it clings to the unfortunate centre of infection is a repetition of what constantly occurs in its oriental homes. In the interests of humanity steps must be immediately taken to make the Richmond Asylum a properly built, properly drained, properly ventilated building for its purposes, and the work of construction must be thorough and must be preceded by all necessary destruction. An inquiry

Digitized by Google

into the diet of the institution might also repay trouble spent upon it. One of the most important points known regarding beri-beri is the fact that it was practically banished from the Japanese navy simply by a change of diet. At one time the number of cases that occurred on board the Japanese men-of-war was so great as to practically threaten the efficiency of the navy. The change to a more liberal and different dietary almost immediately banished the scourge from the Japanese ships. It has also been found in Borneo that when work was rendered almost impossible by the number of deaths from beri-beri amongst the coolies, the labourers could be kept practically healthy by giving them a more liberal diet, and by generally taking care of their ordinary health.

We have very little doubt that nothing short of very stringent measures will suffice to root out the disease that has settled in the Richmond Asylum, and on the mere ground of economy it would probably be better to incur at once a heavy outlay than to endeavour to check the spread of the disease whilst the patients and the unaffected are still housed together in the infected building. The patients would, undoubtedly, have a better chance if removed to huts in an airy situation, and this suggestion need have no terrors for the community. We have said that beri-beri is not contagious from person to person, and this must be reassuring to the Dublin community. Medical men, both in this country and on the Continent, who have occasion to see invalids on ships coming from the East are alike agreed upon this. No one port has the exclusive privilege of producing examples of the malady, but in the seaport towns where it has been observed it has been usually confined to sailors, who have contracted the affection either in the tropical countries from which they have sailed, or on their passage home, or, and more rarely, shortly after their arrival. It has never spread from these sailors to the persons with whom they associated after landing, or who had care of them when they were sick. The element of contagion from person to person seems, therefore, to be so insignificant that it may be ignored.

"Ne quid nimis."

THE PLAGUE AND THE POONA CRIMES.

IT is gratifying to learn, amid all the gloomy news we have of late had from India, that rain has fallen in most districts of the country, that the prospects as regards the future crops are good, and that the pressure and tension which have been caused by the famine are now greatly relieved. India is, we may confidently trust, successfully emerging from the series of severe trials to which she has been subjected. We are glad to learn, too, that a wholesome state of feeling has been exhibited by the greater portion of the native press in regard to the recent murderous outrages at Poona, and that these outrages have been strongly condemned. It is plainly the duty of the Indian Government to adopt strong measures for promptly putting a stop to all incitements to crime and disaffection on the part of the native press. The circumstances connected with the repression of the plague have been altogether exceptional. There has been the eternal conflict between Western civilisation and methods of procedure and oriental religious sentiment and tradition; and the obstacles and difficulties were great on both sides. There is nothing more repugnant to the native mind, nothing which Hindus and Mahommedans more resent, than any interference with the habits of their domestic life or their religious traditions and caste prejudices; and this is not to be wondered at considering all that the loss of caste means to them. On the other hand, it was absolutely essential in the interest of the natives themselves and of everybody concerned that restrictive measures of a hygienic nature should be carried out for controlling the spread of the epidemic. We may be quite sure that the European authorities were as loth to enforce these measures as the natives were opposed to the application of them; the strain was mutual, and based upon strong and honest convictions on both sides. Notwithstanding that the committees for carrying out the powers of the Epidemic Diseases Act were partly composed of natives, female nurses, and female medical practitioners, that they were undertaking a loathsome and perilous task, and that all possible precautions were taken, the action that had to be followed necessarily shocked the religious feelings of the natives and seemed to them a tyrannical interference with their sacred sentiments and customs. Our rule, and a belief in the justice of our conduct, were subjected to very severe strain. The occasion was of quite a different character to the Indian mutiny, for that in its origin and causes was of a military character, whereas this was mainly attributable to the wounded sentiments of the native population fanned by a portion of the disaffected native press. Still, it must be remembered that newspapers do not reach the vast majority of the teeming population of India, who are indifferent and very ignorant and occupied with their daily toil, but superstitious and sensitive to a degree in matters affecting their caste prejudice. When all the circumstances of the case are taken into account it will be seen that the situation was of a critical kind, not from any dimensions that the opposition to our action reached, but from its peculiar nature and the possibilities that lay hidden in it. British rule in India has received a slight but significant shock at Poona. There are so many unforeseen dangers connected with Imperial rule that it is well to be reminded of them from time to time "Lest we forget—lest we forget!"

WATER-GAS.

A DEPUTATION from the Manchester and Salford Sanitary Association recently presented a memorial to the gas committee of the city council expressing concern at the growing practice by municipal gas committees of using water-gas with coal-gas for illuminating purposes. It was pointed out that ordinary coal-gas owes its poisonous properties when respired to the 4 to 8 per cent. of carbon monoxide it contains. Water-gas contains from 40 to 45 per cent. of this gas, and when used to mix with coal- or oil-gas the percentage of carbon monoxide in the illuminating gas thus composed is raised to not less than 18 or 20 per cent., so that it is at least three times as poisonous as ordinary gas. "A person might be fatally poisoned even by a small proportion (as small as 0·5 per cent.) of the gas in air which was respired for some time." Dr. Dixon Mann and Mr. Thomson, the analytical chemist, spoke in support of the memorial, and impressed on the committee the need of warning consumers of the risk of leakage. Mr. Alderman Gibson, chairman of the committee, pointed out the difference between water-gas and water-oil-gas, which latter the committee intended to use. The reason for its use was that with the present plant it was scarcely possible to keep pace with the consumption, that "last year and the year before, making gas night and day, employing their fullest capacity, they were within twenty, or at most thirty, minutes of placing the entire city in darkness. ..... But starting

Digitized by Google

and stopping the making of water-oil-gas was as easy and almost as expeditious as turning off a meter." He went on to say that starting in a morning they could supply 3,000,000 cubic feet in the afternoon to mix with their ordinary coal-gas, while four or five days would be required to do the same with coal-gas retorts. The replies received from London, Liverpool, Belfast, Birmingham, Edinburgh, Blackburn, Stockport, and elsewhere were to the effect that they had not the "report of one single case of poisoning by gas inhalation other than would have occurred by the inhalation of ordinary gas." He also added the remarkable statement: "America was the home of carburetted water-gas, and there were no complaints there as to accidents arising from its proper use." The deputation was asked "to trust the committee in this matter." As it would have been out of order for the deputation to have made any comments on these statements Dr. Dixon Mann wrote next day to the papers, showing how they differed from the report of Dr. Abbott, secretary of the State Board of Health, Massachusetts. The report states that previously to 1878 fatal accidents from breathing coal-gas were very rare, and that up to that time illuminating gas was not allowed to contain more than 10 per cent. of carbon monoxide. This law was repealed and water-gas introduced to an unlimited extent. "The consequence was that in Boston alone, with 450,000 inhabitants, in the year 1890 more deaths took place from illuminating gas than had occurred from the same cause during the preceding fifty years," and "in 1896 no less than forty-three deaths from the same cause occurred in Boston. Dr. Mann is a little satirical on the "profound emphasis" with which the chairman informed the deputation that water-oil-gas and water-gas are two different things, and how he and many members of the committee seemed persuaded that the ignorance of the public at large was fully shared by the Manchester and Salford Sanitary Association, while the committee ignored the fact that water-oil-gas is a mixture of the two, "the poisonous property of water-gas being simply diminished proportionally to the amount of oil-gas which the mixture contains." As Dr. Mann remarks, the objections to the use of water-gas are not only that it may quickly cause fatal poisoning, but because of the loss of health and the actual disease it may produce by chronic poisoning. If this gas is used all gas-fittings must be kept absolutely gas-tight, which we know, taking one house with another, to be a very rare occurrence. Sober-minded people would probably think it better to extend the gasworks than to flood the mains with, and drive through every faulty pipe and leaky fitting, this insidious and deadly compound. We may point out that the question was discussed some years ago in the Report of THE LANCET Sanitary Commission on Gaseous Fuel[1] where some interesting particulars will be found as to the manufacture of oil-gas and water-gas, and the method of mixing these with ordinary illuminating gas.

IMPORTANT DECISION UNDER THE NOTIFICATION ACT

AN important case has just been decided in the Plymouth County Court. Dr. Clay, having in several instances been called in as a consultant in cases of infectious disease, has felt it his duty to comply with the terms of the Infectious Disease (Notification) Act, to the effect that "every medical practitioner ..... called in to visit a patient" shall forthwith notify; and he has, in consequence, sent in a notification certificate in addition to the certificate already sent in by the usual medical attendant. But the Town Council have refused to pay for these duplicate notifications, and hence Dr. Clay took friendly proceedings against them in order to test the validity of their action. The County Court judge, after considering his judgment, has held that Dr. Clay had the duty of notifying under the terms of the Act, quite irrespectively of the fact that the case had already been notified. In our articles as to "Difficulties under the Infectious Disease (Notification) Act," since issued in the form of a pamphlet, we dealt specially with the question of "Multiple Certificates Relating to the Same Patient," and we quoted the view of the Local Government Board to the effect that "if ..... two practitioners are in actual attendance on, or are called in to visit, a patient, whether at the same period or successively, and their attendance or visiting is connected with the medical treatment of the patient, both are in strict law required to send certificates of notification, and these must be duly paid for by the sanitary authority." We need not discuss the question further here, because we have, as already explained, dealt with it before; but we may add that if no second certificate were to be given as regards the same patient nothing would be easier in our large towns than to evade the purposes of the Act. Patients have more than once been moved into rooms some distance away in the same sanitary district in order to escape what their friends deem to be the needless intervention of the officers of the local authority, and a fresh medical practitioner is called in. If such a practitioner, though having knowledge that a notification certificate had been transmitted by the previous practitioner, failed again to notify he would be liable under the Act to be summoned and fined. Indeed, it would be difficult so to contrive a clause that would ensure all needed multiple certificates being transmitted, whilst eliminating such as are not strictly needed, and therefore the clause was drawn as it stands.

CHICAGO SCHOOLS AND MEDICAL INSPECTION.

WE have received the report of the first medical inspection of Chicago Schools, taken under the supervision of Dr. A. Reynolds and Dr. Reilly, the Commissioner and Assistant Commissioner of Health for the city of Chicago. The time covered by the report covers the periods from Sept. 3rd, 1896, to June 30th, 1897, inclusive. The number of children in attendance was 272,000, in 572 separate buildings, and the work was placed in the hands of eight medical inspectors. Day by day every medical inspector was notified of the existence and locality of any case of infectious or contagious disease in his district, "whereupon he proceeded at once to ascertain if the patient had been in attendance at any school; if not, his duties terminated with seeing that the case was properly isolated and the necessary precautions against spread of the contagion or infection on the premises and in the neighbourhood were duly observed. If, on the other hand, the patient had been attending school, the school was at once visited and taken charge of by the inspector so far as relates to carrying out and enforcing precautionary measures against further spread of the disease, to the remedy of insanitary conditions on the school premises, &c. In cases of diphtheria and scarlet fever the throats of the children in the same room as the patient were examined after the method of Dr. Durgin, the teacher was instructed to watch for certain symptoms and to report their appearance to the inspector, and other appropriate action was taken and surveillance maintained as long as deemed necessary." As to the vaccinal condition of the children, 914 school examinations were made, covering a total of 90,220 scholars, and 47,310 vaccinations or re-vaccinations were performed. Of reported diseases diphtheria was the most prevalent, 744 individual cases among school children leading to the discovery of 2619 cases at home. There were 231 school cases of scarlet fever and 745 home cases. Stomatitis was found to be so prevalent in many schools that the inspectors advised teachers to

[1] THE LANCET, Nov. 25th, 1893.

Digitized by Google

instruct pupils to bring their own drinking cups and to forbid the common practice of children sucking water taps. Numberless structural defects in school buildings were reported to the School Board and as far as possible remedied by them. Schools, as everyone knows, are a fruitful source of infection, and we congratulate Chicago upon the institution of regular inspection.

THE FLANNEL SHIRT CLUB.

IN THE LANCET of January 9th, 1897, we referred to the formation of this useful society, which has for its object the supply of flannel shirts to patients who may be discharged from hospital in a destitute condition. The first half year's report has just been issued, and we see from it that eleven metropolitan hospitals have participated in the alms of the society. Those hospitals which were not helped have guilds or funds of their own for the purpose. The first annual meeting was recently held at 5, St. James's-square, kindly lent by the Earl and Countess of Strafford. The Vice-president, Mrs. W. L. Courtney, made a graceful speech, and enthusiastic testimony was borne by many matrons and ward sisters to the benefits afforded to sundry necessitous male patients. We wish every success and prosperity to this society and may mention that shirts may be sent to Miss Lamport, 52, St. John's Wood-road, and subscriptions to Mrs. H. H. Clutton, 2, Portland-place, W.

THE THERAPEUTICS OF THE ANIMAL EXTRACTS.

THE complete success of the treatment of myxœdema by thyroid extract, which was introduced six years ago by Dr. George Murray, was naturally the beginning of a new era in therapeutics. The animal extracts have been extensively used for a large number of diseases, and the literature of the subject is already very extensive. But what has been established as to the value of this new form of treatment? A useful article by Dr. Francis P. Kinnicut in the *American Journal of Medical Sciences* of July well summarises the results up to the present time. What little appears to be established we shall state. The so-called successful results which remain and constitute a large part of the literature are such as are always reported of any new remedy to be followed only by disappointment. In cretinism the myxœdematous symptoms are readily removed by thyroid treatment. Bodily growth and mental development held in abeyance take place in a degree inversely proportional to the age. If the treatment is begun early in the disease the child will probably grow into a healthy adult. In a type of idiot somewhat resembling the cretin some improvement, physical and mental, has been obtained. Some benefit follows the treatment in goitre—especially in the h perplastic form. Large collections of colloid and cysts are not affected. But complete disappearance of the goitre has rarely been observed. In exophthalmic goitre an aggravation of the symptoms usually results. In obesity a loss of weight at the rate of from 2 lb. to 11 lb. a week is produced in some cases. After a time a limit is reached, beyond which further loss does not occur. As a rule, discontinuance of treatment is followed by relapse. In diseases of the skin the expectations entertained have not been fulfilled. In psoriasis definite results have been obtained in some cases; but even in these not better than by modes of treatment already in use. Of 48 cases of Addison's disease treated by suprarenal extract 6 were reported cured, 22 improved, 18 unimproved, and 2 aggravated. Thymus extract appears to be useless in exophthalmic goitre, but beneficial in the other form. Of 30 cases of goitre 20 were improved; but only 2 were cured. Of 13 cases of acromegaly treated with pituitary preparations 7 showed varying degrees of improvement, 5 none, and 1 became worse. In two the violent headache and neuralgic pains in the limbs were diminished. Decrease of the affected extremities occurred in one case.

AN INTERNATIONAL FIRE PREVENTION CONGRESS.

A MOST admirable movement is being organised which will meet, we are sure, with the hearty approbation of all. This is to call together an international congress to discuss the means to prevent and minimise fire in theatres, concert halls, and all other places of public resort where fire may be a source of danger. It is proposed to hold this congress in Paris, where it is hoped also that an international exhibition will be convened which shall illustrate all the appliances, inventions, products, and plans for the prevention of fire. We heartily recommend this proposal to those manufacturers, engineers, and inventors whose time and attention is devoted to the best means of preventing and suppressing fire, and we feel sure that they will be accorded every consideration, and that ample facilities for the exhibition of their appliances will be placed at their disposal in a building commensurate with the requirements and the merits of the exhibits. We repeat, the idea is an admirable one, and we wish it every possible success. Those whose interests are concerned and who have at heart the avoidance of those terrible disasters from fire, painful instances of which have occurred during the last twelve months, should cordially embrace the opportunity thus afforded them of doing a real service in the interests of the public, and should communicate with the British secretary, Mr. Frederick Hoare, of College-chambers, 249½, High Holborn. It is hardly necessary to add that the movement is very strongly supported in France, and we hope it will receive similar support here and in other countries.

THE RINDERPEST.

IN another column we publish a letter from Mr. H. A. Lawrance, F.I.C., in which he puts forward his position in connexion with the rinderpest controversy that is at present raging almost as severely as the disease itself in South Africa. Many of Mr. Lawrance's suggestions appear to have had little foundation, except on analogies between rinderpest and other diseases, but his letter bears evidence that he has followed the question with great care from the outset, and we think it a pity that he should not be allowed to give evidence before the Select Committee which is at present sitting at the Cape. We see, by the way, from recent telegrams that the Cape Government is now perfectly satisfied that Koch's method of preventive or protective inoculation is sound, and that under certain conditions good results may be expected from its use in affected districts. In the meantime the experts at the Cape are actively engaged in determining the exact conditions under which the bile and serum treatment is attended with the best results, and there can be little doubt that it is to these efforts that the good results obtained must, in part at any rate, be attributed. Whilst on this subject it may be well to point out that if Dr. Edington's statements as regards the persistence of the virulence of the infective agent in blood, mucus, &c., that have been desiccated hold good, we in this country should be on the outlook to prevent the introduction of the disease amongst our cattle through the medium of imported wool and hides. Due precautions are, no doubt, taken to sterilise the outer surfaces of bales of these commodities; but if the rinderpest organisms can retain their vitality in the dry wool and hair, the introduction of rinderpest from the Cape into this country may be simply a matter of time. A definite pronouncement on this point should be given at as early a date as possible, and we would

Digitized by Google

suggest that a definite report as to the dangers of this mode of infection should be drawn up immediately.

FORMATION OF GALL-STONES ON SUTURES LEFT AFTER CHOLECYSTOTOMY.

IN the *Boston Medical and Surgical Journal* of July 1st Dr. J. Homans records the following case. Cholecystotomy was performed on a woman and ninety-seven gall-stones were removed. The gall-bladder was united to the peritoneum by silk sutures and drained. The patient made a good recovery and remained free from symptoms until twenty months after the operation, when they began to recur. Cholecystotomy was performed again and seven gall-stones were removed; they were found to have crystallised round the sutures, which had become detached and had dropped into the gall-bladder. Though cholecystotomy has been now performed many times we do not know of any instance in which this accident has happened.

TINNED FOOD.

IT cannot be doubted that certain foods preserved in tins afford an auxiliary and convenient source of food-supply which cannot well be dispensed with, and, that being so, any suggestion calculated to ensure the wholesomeness of the food so preserved is entitled to every consideration. We do not believe that the mischief that now and again arises from the consumption of tinned food is referable to the presence of metal. Tin is a comparatively harmless metal, while the iron over which it is veneered is quite free from risk. The lead in the solder employed may, however, give rise to poisoning, but we believe that so well is the sealing process done that cases of this kind are rare. The dangers of tinned food generally arise from an inherent change in the food itself, and there is no doubt that the longer the food is preserved the greater is the chance of its being unwholesome, while, as is well known, as soon as the food thus preserved is exposed to the air certain changes rapidly set in, and for this reason the food should be partaken of as soon as possible after the tin is opened. Dr. Sykes, the medical officer of health of St. Pancras, makes what would appear to be a useful and practical suggestion in his annual report, which is that the law should provide that all tins containing tinned food shall have stamped upon them the date of tinning. Assuming that the correct date of tinning were thus stamped upon the tin the public would be able to judge in some measure of the wholesomeness of the contents, since it is reasonable to suppose that the enclosed food would not improve on prolonged keeping. We trust that the suggestion will be brought before the notice and consideration of the proper authorities.

EPSOM COLLEGE.

WE are glad to note from the annual report of the Royal Medical Benevolent College for the year ending May, 1897, that the institution shows steady progress. There is an increase in the sum received from annual subscriptions; the amount of donations is satisfactory, seeing that a festival was not held in 1896; and the sum received on school account is larger than it has been for many years. A legacy of £300 for the endowment fund has been received under the will of the late Dr. Henry Fearnside, of Bournemouth, and the residue of the testator's estate is to pass to the College for the same object after the decease of Mrs. Fearnside. The re-building of the chapel is being proceeded with. Four exhibitions or scholarships have been won by students of the College. The health of the boys has been, on the whole, excellent, and the school has been quite full throughout the year. We are glad to be able to congratulate the council upon the continued prosperity which their report shows, and can only wish that it may long continue. Founders' day was held on July 26th, when, in the unavoidable absence of Lord Lister, the Rev. T. N. Hart Smith, the head-master, presided. Among those present were Sir Joseph Fayrer (Chairman of the Council), the Rev. E. W. Northey (deputy chairman), Dr. Constantine Holman (treasurer), Dr. Charles Browne, Dr. Charles Drage, Mr. J. F. France, Dr. J. H. Galton, Mr. Reginald Harrison, Mr. Christopher Heath, Dr. F. Needham, Dr. A. E. Sansom, Mr. L. Smiles, and Colonel Gordon Watson. The chairman announced that during the year the College had exceeded any previous record in the distinctions gained by boys direct from the school. Addresses were delivered by Sir Joseph Fayrer, Dr. Holman, and Mr. Christopher Heath. In the course of the proceedings it was announced that a cheque had been received from Lord Rosebery defraying the debt on the organ which had been erected in the new chapel.

THE SELECT COMMITTEE ON PETROLEUM.

AS might have been anticipated, the members of this committee, which has sat for a long time now, still find that their investigation is not complete. They were appointed to inquire into, and report upon, the sufficiency of the law relating to the keeping, selling, using, and conveying of petroleum and other inflammable liquids, and the precautions to be adopted for the prevention of accidents with petroleum lamps. It is regrettable that they have not yet arrived at any definite conclusions or recommendations, especially in regard to that clause in their inquiry relating to dangerous lamps. But it must be admitted that legislation in relation to the sale of lamps and oil will require the most serious consideration before any final plan can be adopted. Then, again, there is considerable diversity of opinion as to whether any extension of the Petroleum Act should apply to the construction of lamps or to the raising of the flash point of the oil. However, "at this late period of the session the committee are of opinion that it will not be in their power to conclude their investigation," so they have agreed "to report the evidence already taken to the House and to recommend that a committee on the same subject should be appointed early in the next session of Parliament." We regret that the committee have lost an excellent chairman in the person of the late Mr. Mundella.

THE MEDICAL WORK OF THE LONDON COUNTY COUNCIL.

THE address on the report of the London County Council for 1896-97 is of special interest to us on account of its being the first one delivered by the first medical chairman that body has elected. The works of the Council are so many and various that we have only space to mention those which more especially concern ourselves as medical journalists. And first on the list comes the Asylums Committee. The number of persons of unsound mind coming within the jurisdiction of the county of London is 13,526, as compared with 10,104 in 1890, and a new county asylum with 2000 beds is being erected at Horton Manor. Dr. Collins expressed a hope that before another year or so Londoners may expect the "excrescence of Holywell-street to be conspicuous by its absence." We do not see the use of pulling down Holywell-street unless the two churches of St. Mary-le-Strand and St. Clement Danes are sacrificed too, and even then Fleet-street and the Strand will be far too narrow for the traffic. Some of the host of omnibuses ought to be made to go along the Embankment and so relieve the congested streets. The Drainage Committee report that during the past year 2,184,500 tons of sludge were taken out to sea from Barking and Crossness and discharged into Barrow Deep, and we are glad to see that dredgings made at this spot gave no

Digitized by Google

evidence of sewage pollution. The Public Control Committee report that cases of glanders have fallen continuously from 2336 in 1892-3 to 867 in 1896-7, which is very satisfactory, as a number of such cases have been reported by the use of mallein as a diagnostic. The committee on inquests, &c., has been doing very useful work. In the words of the chairman, "arrangements have been made, or are now approaching completion, throughout all the districts in London, which will practically obviate the necessity for holding any inquest amid the desecrating surroundings of the public-house. In coöperation with the various sanitary authorities good mortuary accommodation has now been provided in nearly all districts. Such mortuaries are increasingly used for the reception of bodies awaiting interment in other than inquest cases. The public are recognising the advantage of the removal of dead bodies, during the interval between death and interment, from crowded houses to decent mortuaries, where sentiment is respected and sanitation satisfied." This is good news to us, for it is a point upon which we have insisted for years. We shall deal later with the report as a whole, and must congratulate Dr. Collins upon the successful work of the great body over which he has been called to preside.

THE VENOMS OF THE TOAD AND SALAMANDER.

IT has long been known that both the toad and salamander are of a venomous nature. Shakespeare, as everyone knows, refers to the toad as a source of ingredient in the mystical mixing of a charm-producing preparation, and in one instance to a toad which had "sweltered venom sleeping got." Pliny also says of the salamander that "of all venomous beasts there is none so hurtful and dangerous." In a very interesting paper on this subject in the July issue of *Science Progress* Dr. Hewlett shows that the employment of preparations of the toad as remedies for dropsy is not so absurd as may at first appear, for, as he has shown, a substance is secreted by the skin very like digitalin, and hence possibly having a favourable effect in cases of cardiac dropsy. It would appear that the active principles of the venoms of the toad and salamander are totally different substances from those of snake venom, the former being alkaloidal, while the latter are proteid in nature. Curiously enough, the venom of the toad and salamander is fatal to the animal which secretes it, only in comparatively large amounts. The salamander appears to be remarkably refractory to certain poisons; it is only completely "curarised" by forty-three milligrammes of curare, while morphine is apparently quite inactive. It was demonstrated by actual experiment that the salamander's blood and blood serum act as an antitoxin towards curare. The paper is a very interesting one, not only as tending to throw light upon the action of poison, but in also showing that the belief of the ancients in the venomous nature of the toad and salamander was not altogether devoid of foundation.

THE FORTHCOMING CONGRESS OF THE SANITARY INSTITUTE.

THE preliminary programme of the Sixteenth Congress to be held in Leeds from September 14th to 18th, has now been issued. The President of the Congress is Robert Farquharson, M D Edin., LL D. Aberd., F.R C.P. Lond., M.P., D.L., J.P. The congress will include three general addresses and lectures; three sections, meeting for two days each, dealing with (1) Sanitary Science and Preventive Medicine, presided over by T. Pridgin Teale, M.A., M.B. Oxon., F.R.C.S. Eng., F.R S.; (2) Engineering and Architecture, presided over by Lewis Angell, M. Inst. C.E., F.R.I.B A.; and (3) Chemistry, Meteorology, and Geology, presided over by Wm. Whitaker, B.A., F.G.S., F.R.S.; and six special conferences, River Pollution, presided over by Major L. Flower, sanitary engineer, Lee Conservancy Board; Municipal Representatives, presided over by Councillor B. Womersley, chairman of the sanitary committee, Leeds City Council; Medical Officers of Health, presided over by Edward Seaton, M.D., F.R.C.P. Lond., F.C.S.; Municipal and County Engineers, presided over by Thomas Hewson, M. Inst. C.E.; Sanitary Inspectors, presided over by Peter Fyfe, F.R.S. Edin.; and Domestic Hygiene. In connexion with the congress a health exhibition of apparatus and appliances relating to health and domestic use will be held, and excursions to places of interest in connexion with sanitation will be arranged. These local arrangements are in the hands of an influential committee, presided over by the Lord Mayor of Leeds, with Dr. J. Spottiswoode Cameron, medical officer of health of the city, Mr. A. E. Pearson, M.R.C.S, L.R C.P. Edin., and Mr. W. Spinks, Assoc. M. Inst. C.E, as honorary secretaries. We understand that there are good reasons for expecting a large attendance.

CANCER CURERS.

MR. WILLIAM LENNOX WATSON is a lucky man. He is in possession of a receipt for the cure of cancer handed down from his father, and he gives his advice and the cure free—in which respect we must say he differs from the ordinary tribe of quacks. Like another celebrated benefactor, he does "good" by stealth, and blushes to find it fame, for, in explanation of his using the name of Hudson, he handed in a statement saying that he used and assumed the name because he was not proud of his connexion with the business. The cure consists of a plaster, in which the active ingredient is arsenic, and the plaster is to be applied to the skin after the epidermis has been removed by a blister. It is to remain on for fourteen days. Miss Blacker, for whose manslaughter Watson was indicted, against his instructions, kept the plaster on from May 13th until June 3rd, when she died from, as the post-mortem examination showed, arsenical poisoning. Absorption of the poison must have been rapid, for evidence was given that when in the train, returning to York on the day of application of the plaster, Miss Blacker was attacked with sickness and diarrhœa, which the accused stated in the letter was "quite the usual thing with the plaster." Mr. Justice Grantham summed up strongly in favour of the prisoner, and the jury returned a verdict of "Not guilty"—a verdict which appears to us to be absolutely wrong. Miss Blacker, we notice, was lured to her death by an advertisement in a religious paper. We have frequently commented before upon the way in which the so-called religious papers insert advertisements of quack remedies and those calculated to produce abortion, and we must say it is a disgrace for any paper, and especially a "religious" one, to prostitute its columns to such purposes. We can only express a hope that Mr. "Hudson" will not merely feel ashamed of his business, but will give it up for the future.

HEALTH OF THE ARMY IN INDIA.

WE think that all reasonable people may be congratulated on the altered tone which has of late characterised the discussion regarding the measures that should be adopted for limiting the spread of "the most serious, insidious, and lasting of all the contagious diseases that afflict humanity." As to the moral and religious aspect of the question, we have always contended that whatever might have been urged against the Contagious Diseases Acts, the benefit they conferred on the unfortunate women in this direction was very great. Detention in hospital gave an opportunity of their being reached by kindly moral influences and afforded them time for rest and reflection while their physical ailments were being treated. We know

Digitized by Google

of no better or more practical way of conveying philanthropic and Christian influences to them than by carrying these to their bedsides when sick. Then, again, the order and decency of our streets were improved and their temptations lessened, and a wholesome restraint was imposed upon many vain, giddy, and thoughtless girls by the fear lest their conduct should attract attention. The opponents of all legislative action in regard to the spread of these diseases appear to think that all physical measures are incompatible with moral and religious methods of dealing with the evil. We would commend to the attention of our readers the excellent and exhaustive letter from Mrs. Louisa Herbert, which appeared in the *Times* of the 17th inst., wherein it is wisely said that "practical religion is really sanctified common sense." The recent speech made by the Lieutenant-Governor of the Punjab, Sir W. Mackworth Young, on the new policy proposed to be adopted by the Indian Government in regard to this form of contagious disease is also worth reading as indicative of the view taken by a conscientious man of strong religious convictions. All this shows that there is, at any rate, a growing disposition to look the facts in the face—from a prudent as well as a merciful and Christian point of view.

THE EXPLOSIVES ACT.

THE annual report of Her Majesty's Inspectors of Explosives for the year 1896 is again satisfactory. There can be little doubt that in this department of control this country leads the way. This is evident from the fact that the Governments abroad are constantly inquiring into the working of our Acts with a view to the improvement of their own. The number of deaths from accidents by fire or explosion connected with manufacture during the year was one only, which, as the inspectors observe, marks an extraordinary and most satisfactory contrast with the figures which obtained before the Act came into operation This result is all the more satisfactory when it is considered that not only has the actual number of factories largely increased, but in many cases the amount of output of an individual factory also, and consequently the number of hands employed and the resulting chances of accident. Further, the risks attending the preparation of explosives that are quite new, to the manufacture of which a large proportion of the recently built factories are applied, are less well known than those connected with the more familiar explosives, and therefore they are not so easy to provide against. And these results have been accomplished without any undue or even inconvenient interference with the trade. The number of accidents in the various industrial applications of explosives shows also a considerable decrease, namely, 134 against 152. The number of deaths from accidents of this class shows also a decrease, namely, 33 against 40, the returns this year being slightly below the decennial average.

THE EPPING FOREST GIPSIES.

FROM time immemorial the forests of Epping and Hainault have been the resort of wanderers and outcasts, and at the present time certain parts of the forest are infested by tent- and van-dwellers, who voluntarily keep without the pale of civilised society, and are generally a nuisance to the inhabitants around. Many attempts have been made to clear them from the forest, but hitherto without result; they have removed from one part only to become a nuisance in another. In 1894 the Essex County Council made a series of by-laws to prevent tent-dwellers, squatters, gipsies, or other persons from using as a dwelling-place so as to cause annoyance, injury, or disturbance to residents in the neighbourhood any tent or van or similar structure placed on any land within two hundred yards of any highway or street or of any dwelling-place. These by-laws were to apply to the whole county, but the Secretary of State refused to sanction them save for that portion of the county which is situated within the metropolitan police district. The result has been that the southern part of the forest, which is within the police district, has been practically cleared of gipsies, whilst the numbers in other parts have increased. At Lambourne End, a portion of the old forest of Hainault, there are about 200 squatters, who are causing great anxiety to the authorities. The county council appears to be powerless, and all the efforts made by the Ongar rural district council to dislodge them have been of no avail. When legal notices of any kind are served upon them they simply pack up their tents and remove to another portion of the forest. At the last meeting of the district council the Lambourne parishioners drew the attention of the members to the large increase in the number of gipsies and to the great nuisance caused by them. After a considerable amount of discussion, during which the action of the Secretary of State was adversely criticised, it was decided that the surveyor should obtain the "names of the gipsies and serve them with notices to provide sanitary appliances and a proper water-supply." The clerk urged that it would be better to worry the Secretary of State, as when the notices were served on the gipsies they would remove to another district for a time and then come back. This is, no doubt, what will occur, and we cannot but think that if reasonable by-laws were framed and the whole facts of the case laid before the Secretary of State his formal approval would be obtained. Until this is done there is little hope of remedying the present disgraceful condition of Hainault Forest.

THE LOUGHBOROUGH MEDICAL AID ASSOCIATION.

THE above association has recently been advertising for a duly qualified medical officer, salary £400 a year, with midwifery fees, which average about £30 per annum (the per case fee being 10*s.*), and a residence. At first sight this would seem to be fairly good pay as things go, but the medical officer is expected to provide a duly qualified assistant out of his receipts. From the medical report for the year ending December, 1896, we learn that 9035 visits were paid and an average of 120 prescriptions a day dispensed. The total receipts of the association were £1169 14*s.* 2½*d.* Adding up all the items debited to medical expenses—viz., salaries, midwifery fees, cab fares, rates, taxes, drugs, dispensing, bottles, rent, coals, gas (which we count as being all for medical purposes)—we come to a grand total of £726 11*s.* 0½*d.* Deducting this from the total we have £443 3*s.* 2*d.*, and if, to be perfectly fair, we deduct the secretary's salary, £126, and the auditor's fee, £1 10*s*, we have £315 13*s.* 2*d.* remaining over. This sum ought to be divided among the medical officers, except some small portion to be regularly applied as a sinking fund against loans or legal expenses. The secretary, we see, is also dispenser, and considering that he dispensed some 43,000 prescriptions he cannot be considered overpaid. The official balance-sheet shows a balance of £176 odd, and in our opinion a society that makes a clear profit of, according to its own accounts, £176 odd out of medical aid and dispensing, with a gross expenditure of just under £1200, can only be called by one term—namely, a sweating society. By the rules the medical officers must give their whole time to the association and shall not engage in private practice either professionally or otherwise (whatever that may mean) and shall provide their own instruments. A medical aid association, as we have often said, is only to be justified where the medical officers have a voice in the management of the affairs, a right of objection to the admission of members earning above a

Digitized by Google

certain wage, and where the association does not tout for members. We do not see in this association why the medical officers should not receive the whole of the members' payments after deducting the cost of drugs and quarters, for the only benefit offered to members is medical service.

AT a recent meeting of the provisional committee of the movement for providing a memorial in Bristol of the late Mr. Greig Smith, it was resolved that in order to perpetuate the memory of the deceased surgeon an appeal should be made for subscriptions to provide a bust or medallion to be placed, if permission be obtained, in the Bristol Museum and Library or some other public institution; also that a medallion be placed in the operating room at the Bristol Royal Infirmary, and that the balance of the money collected be applied in assisting to carry out the scheme at the operation theatre drawn up by the late Mr. Greig Smith.

H.R.H. PRINCESS CHRISTIAN visited Norwood Cottage Hospital on July 16th, and then attended a garden party at the residence of the President, Mr. C. E. Tritton, M.P., where she received purses on behalf of the special Diamond Jubilee Fund in aid of the hospital. This fund was instituted early in the year, chiefly with a view to the support of the Hokkaido bed at the hospital and a bed at the Convalescent Home, Bexhill. It was stated that the subscriptions to it amounted to about £3000, a result which was largely due to the energy of Mrs. Gandy, wife of one of the surgeons.

AT the annual meeting of the St. Andrews Graduates' Association held at 11, Chandos-street, W., on Thursday, July 22nd, Dr. Cleveland, who had filled the office of chairman *pro tempore* since the lamented death of Sir Benjamin Ward Richardson, was elected President of the Council for the ensuing year. At the same time Sir Charles Gordon, K.C.B., and Sir Charles Gage-Brown were elected Vice-presidents of the Association.

WE regret to record the death, on July 22nd, of Dr. Henry Thompson at the advanced age of eighty-one years. Dr. Thompson at the time of his death was consulting physician to the Middlesex Hospital, having resigned the office of physician in 1879. He was also Senior Fellow of St. John's College, Cambridge.

THE medical service in State, under the auspices of the Guild of St. Luke, will be held this year in St. Paul's Cathedral on Oct. 19th at 7.30 P.M. The Archbishop of York will preach, and we are further informed that academical dress will be worn by members of the medical profession who are graduates.

THE Vice-Chancellor of the University of Cambridge (Dr. Alexander Hill) will preside at the annual distribution of prizes and certificates to the Students of the St. George's Hospital Medical School this year. The ceremony will take place in the new board-room of the hospital on Friday, Oct. 29th, at 3 P.M.

H.R.H. PRINCESS HENRY OF BATTENBERG, the Governor of the Isle of Wight, lays the foundation-stone to-day (Saturday) of the new buildings of the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor.

THE proposals of the Indian Government with regard to the Secretary of State's despatch concerning the health of the troops in India have been published as a Parliamentary paper, and we hope to make some remarks thereon next week.

Pharmacology and Therapeutics.

ICHTHALBIN.

THE unpleasant taste and smell of ichthyol have, in England at least, presented serious obstacles to the internal use of this really valuable drug. Attempts have been made to disguise the odour by means of citronelle, coffee, and other substances, but unfortunately with only very partial success. The active principle of ichthyol is generally admitted to be sulpho-ichthyolic acid, which exists in it to the extent of 53 per cent. This acid Dr. Sack, of Heidelberg, has recently succeeded in combining with albumin, forming a brownish-grey powder insoluble in acids, but decomposed by alkalies. This substance has neither taste nor smell and contains 40 per cent. of sulpho-ichthyolic acid, so that three grains of it are about equivalent to four of ichthyol. It passes unchanged through the stomach, but in the alkaline media of the intestine it slowly breaks up into sulpho-ichthyolate of soda and peptone. It has proved useful in rachitis, anæmia, tuberculosis, syphilis, and in various intestinal affections, the digestion being improved, the bowels made regular, the appetite increased, and also—often to a remarkable degree—the body weight; in several cases of eczema in children, too, it has proved beneficial. Of course, it is hardly so well suited for external employment as ichthyol itself; nevertheless, it has been successfully applied to the anus for fissures and pruritus. The dose is said to be half a teaspoonful of the powder two or three times a day. It may be taken dry on the tongue and washed down with water or mixed with a little powdered chocolate in which way children like it best.

THEOBROMIN IN SENILE ASYSTOLIA.

Dr. Baronaki has found very great benefit from the administration of theobromin in cases of asystolia in old persons due to degeneration of the muscular walls of the organ. When, however, the asthenia depends upon lung or hepatic trouble this drug is of much less value. In order to obtain its full effect he puts the patient on a purely milk diet with 30 minims of tincture of digitalis *per diem* for four days. He then substitutes for the digitalis theobromin, which is prescribed in seven and a half grain powders every two hours during the daytime, so that six powders, or forty-five grains of theobromin, are taken during the twenty-four hours. The diuretic effects of this are generally observed after a few doses and the œdema and uræmic symptoms disappear. After this result has been obtained it is not advisable to continue the drug, as it is liable to produce sickness, giddiness, and mental excitement. It is best to order iodide of potassium, and then if the symptoms of asystolia reappear to repeat the course of digitalis and theobromin. In very grave cases, where the effect of the drug rapidly passes off and there appears to be danger in giving the digitalis too often, Dr. Baronaki has found the theobromin recover its diuretic power after venesection or scarification of the lower extremities. He has no doubt in his own mind that he has been able by this method to materially prolong the lives of several old persons who, from their appearance and symptoms, would, if treated in other ways, have very rapidly succumbed to an attack of cardiac asthenia.[1]

CARBOLIC ACID IN INFECTING CORNEAL ULCERS.

According to Dr. Geirsvold, a Norwegian practitioner, infecting ulcers of the cornea may frequently be very successfully treated by touching the surface with a Bowman's probe dipped in pure carbolic acid. Some of his cases were complicated by suppuration of the lacrymal ducts, and he was not obliged to use the thermo-cautery, curetting, or sub-conjunctival antiseptic injections.

SALICYLATE OF METHYL IN HERPES ZOSTER.

Dr. Chambard-Hénon of Lyons has found that the pain of herpes zoster may be very rapidly relieved by rubbing salicylate of methyl well into the healthy skin surrounding the eruption. In a case which he publishes he used eighty drops for each application. He lays waxed cloth on the surface and covers the whole with a layer of cotton wool and a bandage.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

MOSCOW: AUGUST 19TH—26TH.

Former Congresses.—The Beauties of Moscow.—"Our Lady of Vladimir" and the Ikon painted by St. Luke.—Biographical Notes of the Organisers of the Moscow Congress.

EXACTLY thirty years have passed since the first International Medical Congress was held. It was in Paris in 1867, when the earliest of those great exhibitions for which the French capital has since become so famous was about to be opened, that the idea arose of summoning such a conference. About five hundred medical men from foreign countries responded to the invitation, and in this modest way the series of triennial gatherings was inaugurated. Had the triennial interval been observed from the beginning the Congress which is about to meet in Moscow would have been the eleventh instead of the twelfth of the series. But it will be seen from the following little table that at first the interval between the successive gatherings was only two years, the change to three years having been made only in 1881. On two occasions the Congress has had to be postponed; in 1871 no Congress was held on account of the Franco-German War, and in 1893 the gathering was put off for one year on account of the cholera epidemic then prevailing.

Table giving the Dates, Places of Meeting, and Names of Presidents of the Previous Congresses.

Number of Congress.	Date.	Place of meeting.	Name of President.
First	1867	Paris.	Professor Bouillaud.
Second	1869	Florence.	Professor Salvatore de Renzi.
Third	1873	Vienna.	Professor Rokitanski.
Fourth	1875	Brussels.	Professor Vleminckx.
Fifth...	1877	Geneva.	Professor Karl Vogt.
Sixth	1879	Amsterdam.	Professor Donders.
Seventh	1881	London.	Sir James Paget.
Eighth	1884	Copenhagen.	Professor Panum.
Ninth	1887	Washington.	Professor Nathan Smith Davis.
Tenth	1890	Berlin.	Professor Virchow.
Eleventh... ...	1894	Rome.	Professor Baccelli.

The Twelfth Congress will be held in Moscow in this present year of grace between the dates of Aug. 7th (19th) and Aug. 14th (26th), the first dates being O.S. The President of the whole Congress has yet to be elected, but it may not be rash to prophesy that the choice will lie between Professor Skliffosowski and Professor Klein, the joint presidents of the Organising Committee. It will be observed that the number of European countries in which congresses have not yet been held is a rapidly diminishing one. At the last congress but one invitations for the present gathering were offered by the representatives both of Russia and of Spain, neither of which countries have as yet been the scene of congresses. The Russian invitation was accepted. The question whether the meetings should take place in Moscow or St. Petersburg was left entirely to the discretion of the Russians, and there can be little doubt in the mind of anyone familiar with the two cities that the choice of Moscow has been in every way the right one. Not but that, in the absence of a rival capital, St. Petersburg would have made an admirable centre for an international gathering of medical men. Lying proudly on the reclaimed banks of the Neva, with her massive palaces and cathedrals standing as firmly as if they were built upon rock instead of upon millions of piles driven into a marshy soil, she is the very type and embodiment of the triumph of man over the adverse forces of Nature. She can offer many sights of interest, and even of beauty, and for medical men the attractions in the way of large hospitals, cliniques, and scientific institutions of all kinds are numerous. But St. Petersburg is not Moscow. It is, perhaps, not without significance that in writing of great cities we should unconsciously speak of them in the feminine rather than in the neuter gender. A great city has a distinct physiognomy of its own, and in this, as in a woman's face, one instinctively looks for character and beauty. In both of these attributes Moscow is richer, not only than St. Petersburg, but than most other cities of the world. To have seen Moscow once is to acknowledge this—that to realise to the full her curious beauty and power of fascination she should be seen many times, under varying conditions as it were, in all her different moods. Moscow seen under an almost tropical July sun, when the Kremlin Hill, with its gold-capped cathedrals and towers and palaces, literally glitters like a gem-covered crown set in an enamelled field of red and green and gold and purple (for in such bright colours are the roofs of churches, houses, and monasteries painted), is one thing; but Moscow in winter, in a raging snowstorm, when the silence of the streets, the drifting clouds of grey powder, and the soft white covering which for a time blots out or tones down the occasionally too brilliant colours of tower and roof, lend an air of mystery to the scene, is another and no less beautiful thing. Moscow should be seen, if possible, at night, when the moonlight plays curious tricks with the gold domes and fantastic lights and shadows of the Kremlin. She should be seen (but this sight occurs but once in a lifetime) when, as in May of last year, the city has adorned herself in the most lavish decorations to welcome the Czar and Czaritza on the occasion of a coronation, and when the spectator is led to question which is the more beautiful, the city or the pageants enacted within her walls. And, lastly—perhaps the most wonderful sight of all—Moscow should be seen illuminated, with every tower and spire and wall and dome covered with a million lights, as on the three nights following a coronation. To have seen this in the warm twilight of a northern summer night is to have seen a spectacle such as few other cities could present. She will be in more sober guise next month, as befits the occasion of a learned gathering such as the Medical Congress and the part of hostess which she will be called upon to play. True to the traditions of Russian hospitality, Moscow has already made great preparations for the reception of her numerous visitors, and there can be little doubt that the coming Congress will yield to none of its predecessors in the care of the hosts to provide for the comfort and enjoyment of the guests.

But Moscow is not less historically interesting than she is externally beautiful. The city is thought to have been founded in the year 1147 by Prince George Dolgorukof, a son of Vladimir Monomach, who had married Gytha, the daughter of our own Saxon King Harold, the first and only Russian ruler who has married a purely English princess. It was in the fourteenth century that Moscow became the capital of Russia. Kief, the earliest capital, had given way to Vladimir, Vladimir was succeeded by Tver, and Tver yielded to Moscow in the reign of the first Ivan. It was this prince who made of Moscow a great city, and there are many traces of him still left. Two of the three cathedrals, those of the Assumption and of the Archangel Michael, were built by him almost as they now stand on the top of the Kremlin Hill. The further history of the city can scarcely be told here, full of interest though it is, without encroaching upon too great a space. Moscow has had to contend with many disastrous visitations—Tatar and Polish invasions, plague, fire, and famine. But she gallantly survived them all, and it was only at the beginning of the eighteenth century that she had to yield some of her laurels and privileges to her young rival, the new city built by Peter the Great, where the Neva flows into the Finnish Gulf. The submission has, however, been more apparent than real. It was at Moscow rather than at St. Petersburg that Napoleon struck his terrific but ineffectual blow in 1812, when the greater part of the city was voluntarily sacrificed to fire in order to save the country from falling into the hands of the enemy. And Moscow is still the *pervo-prestolnaia*, or primary capital of the Empire, the city where the Czars are crowned and christened, although the place of burial has long since been removed to the fortress church of St. Peter and St. Paul in St. Petersburg.

The great centre of interest in Moscow is the Kremlin. "What is the Kremlin?" is a question constantly asked. It should rather be, "What is a Kremlin?" Moscow is not unique in possessing one; they are to be found in several other old Russian towns—in Kazan, for example, and in Nizhni-Novgorod. But none of these have obtained the wide fame of the Moscow Kremlin, and deservedly so, for

Digitized by Google

none can compare with it in size and magnificence or in historical interest. There is some doubt as to the exact meaning of the word itself; but it is thought to be derived from the same root as the word *Krépost*, a fortress, and the word *Krépkir*, strong. The Kremlin in Moscow is more than a fortress; it may best be described as an enclosed space, some two miles in circumference, surrounded by splendid walls, from twenty to fifty feet in height, with curious, almost bizarre, towers and gates at intervals. Within the enclosed space are found a number of important buildings, the "palais de justice," the arsenal, the Imperial palaces, old and new, more than one monastery and convent, the treasury of the Holy Governing Synod, the Bell-tower of Ivan Veliki (or Ivan the Great), the famous Great Bell of Moscow, and last, but not least, the three cathedrals, which, with bell-tower, crown the hill upon which the Kremlin is built. These three curiously beautiful churches represent, as it were, an epitome of the lives of the Czars. In the Cathedral of the Annunciation, the *Blagoviéshtchinski Sobor*, they are christened and, in accordance with the custom of the Eastern Church, receive the Communion immediately after the baptismal rite. In the Cathedral of the Assumption, the *Uspienski Sobor*, the Czar crowns first himself and then the Czarí'za. In the Cathedral of St. Michael the Archangel, the *Archangelski Sobor*, all the ancient Czars of Muscovy, down to the time of Peter the Great, lie buried.

The external aspect of the three miniature cathedrals is impressive and dignified, and this is particularly so in the case of the Cathedral of the Assumption, the largest of the three, whose tall, plain, white walls are relieved in their upper part by bright Byzantine frescoes. But the most lavish decoration has been reserved for the interior of the churches There can be few more beautiful things in Eastern Christendom than the interior of the *Uspienski Sobor*. The central of the five domes is supported by four pillars; and walls, domes, and pillars are entirely covered with frescoes. The effect is one of great richness and beauty. In preparation for the coronation of last year the whole series of frescoes was thoroughly cleansed and restored. The work was done with great care and judgment and under the auspices of the most learned and judicious authorities upon this beautiful art, so that the restoration, which was held to be a necessity, could not in all probability have been better carried out. And yet we may be pardoned perhaps for regretting the richer and more sombre effect that time, and doubtless a generous layer of dust, had lent the coloured surfaces before they were touched by the hand of the renovator. The *ikonostas* is, and always must be, one of the most beautiful features of the church. This, the great screen covered with ikons, or painted religious pictures, stretches across the cathedral from side to side, and divides the body of the church from the sanctuary behind it. There are five tiers of paintings in the screen, set in a gold framework, and some of them almost covered with gold, so that the hands and faces of the painted figures alone remain visible. In the lowest tier are many of the most famous ikons in Russia. Some are undoubtedly of a great age, and most of them have played a part in the history of the country. Like the frescoes on the walls, the figures are for the most part curiously stiff and archaic, but none the less full of that devotional character found in all Byzantine Christian art. Most venerated of all the ikons is a small one enclosed in a gilt shrine, and not always open to the inspection of the curious. The thick incrustation of rough-cut jewels with which it is covered indicates the veneration with which it is regarded by the rich; the worn look of the metal work just underneath the figure, where thousands of lips have been pressed in the act of kissing, show the respect and adoration paid to it by rich and poor; and the black, indistinguishable features and outlines of the painting are proof of its great age. It is even said to have been painted by the physician-evangelist, St. Luke himself, and so may be regarded with double interest by the followers of his honourable profession. The ikon represents the Madonna and child, and is known as the "Vladimir Mother of God" (*Vladimirskaia Bojaia Matj*); its shrine is on the left of the central doors of the ikonostas.

All the three cathedrals are rich in tombs and relics. Three of the four great historical patriarchs of Moscow, St. Peter, St. Jonah, and St. Philip, lie buried in the corners of the *Uspienski Sobor*. The Cathedral of the Archangel is full to overflowing of the velvet-covered sarcophagi of the ancient Czars. There are no tombs in the Cathedral of the Annunciation, but there is a most wonderful collection of saintly relics in this church—ulnas and tibias, carpal bones, and femurs in abundance, and many other parts of the human body, each in its own niche of large gilt and glass-covered cases. Each is inscribed with the name of the saint of whose earthly frame it once formed a fragment, and whose more spiritual part is long since "with the saints, we trust."

It is difficult not to linger in and about the cathedrals of the Kremlin. But there are a number of other interesting sights to be seen; there is the Bell Tower of Ivan Veliki to be climbed for those who are energetic enough to mount many hundreds of steps for the sake of a really fine view. There is the palace, of which the superb modern rooms and curious and interesting old rooms (in the so-called "*Terem*") ought certainly to be visited by a conscientious sightseer, who (like all conscientious sightseers) will be well rewarded for his pains. The Treasury of the Kremlin (*Orujeinaia Palata*) and the Treasury (*Riznitza*) of the Synod contain a wealth of beautiful things which must on no account be missed. The *Czar Kolokol* and *Czar Pushka* ("King Bell" and "King Cannon") are of such a size that they can scarcely be passed by unnoticed. Just outside the Kremlin is the extraordinary church of *Vassili Blajennui*, built by Ivan the Terrible, who, so runs the story, put out the eyes of the architect that he should never build another church to rival it. But for these and all the other sights of Moscow the reader must turn to the pages of his faithful "Murray," where he will find all possible information and help that he can require. Enough has been said to prove beyond question that, with so many interesting things to be seen in the intervals between the more serious labours of the Congress and the social engagements in connexion with it, no one who goes to Moscow this August need fear that time will hang heavily upon his hands.

The Russian Committee of the Eleventh International Congress, held in Rome three years ago, was presided over by Professor Pashutin, whose name has already been mentioned in these columns. When the Russian invitation to hold the next congress in the Empire of the Czars was accepted, Professor Pashutin formally addressed the Medical Faculty of the University of Moscow with the request that it would undertake the far from light duties of organising the Congress. The Faculty accepted the proposal, and a "Preliminary Commission," consisting of seven of the leading medical professors, was formed. In September, 1894, the Organising Committee of the Congress, consisting of all the professors in the Medical Faculty, under the presidency of the Curator of the Moscow Educational District, came into existence; and at the same time the executive committee, of eight members, under the presidency of the Dean of Faculty, Professor Klein, was elected. The executive committee consisted, in addition to the president, of Professor Kojevnikof, vice-president; Professor Erismann, general secretary; Professor Filatof, treasurer; Professor Diakonof, Professor Neiding, and Professor Tikhomirof, all with the title of secretaries; and Professor Ostrōumof and Professor Korsakof as members. In October of last year several changes were made in the constitution of these committees. The curator of the Educational District retired from the presidency of the organising committee, and was succeeded by Professor Skliffosowski; but in view of the fact that the new president resides in St. Petersburg (where he is in charge of the Helena Clinical Institute), Professor Klein was appointed joint president with him. Professor Roth succeeded Professor Erismann as general secretary, and Professor Ognef and Professor Shervinski were added to the executive committee from which Professor Ostrōumof had retired. It should also be stated that a large number of names had in the meantime been added to the organising committee, including those of the Rector of Moscow University, the mayor and vice-mayor of Moscow, Dr. Pashutin of St. Petersburg, Dr. Ragozin, the director of the Medical Department, Dr. Anrep, of the Women's Medical Institute, Dr. Lukianof, of the Imperial (once the Oldenburg) Institute of Experimental Medicine, Dr. Kudrin for the navy, Dr. Remmert for the army, and a large number of other prominent persons whose names are too numerous to mention.

The Congress was almost from the first under the patronage of His Imperial Highness the Grand Duke Serge, whose name is familiar to all Englishmen, and whose tall and commanding figure must have been seen by not a few at the time of the recent Jubilee, when, as on the like occasion in 1887, Russia was represented by him. The Grand Duke Serge is Governor-General of Moscow, and is married to a grand-daughter of the Queen, the Princess Elizabeth of Hesse, who is also a

Digitized by Google

sister of the present Czaritza. Last winter His Majesty the Czar was graciously pleased to become a patron of the Congress, and he has still further shown his interest in it by consenting to receive deputations from all the countries represented at the Congress.

FIG. 1.

His Imperial Majesty the Czar of Russia, "High Protector" of the Congress.

The necessary expenses in connexion with the Congress were soon guaranteed. The Government granted an initial sum of 50,000 roubles, which has since been increased to 75,000 (equivalent to about £8000). The municipality of Moscow has also voted generous sums of money, and these have been increased by votes from the Government *zemstvo*

FIG. 2.

His Imperial Highness the Grand Duke Serge Alexandrovitch, "August Patron" of the Congress.

of Moscow and other sources. In addition to this, the Russian railways, nearly all of which are now under State management, have arranged to grant free railway tickets to Russian members of the Congress from any part of the empire, and to foreign members from any frontier town to Moscow and back.

The Office-bearers of the Congress.

Professor Nikolai Vasilievitch Skliffosowski, the President of the Organising Committee of the Congress, and one of the foremost of Russian surgeons, was for many years associated with the University of Moscow, but four years ago he accepted the appointment of Director of the Helena Clinical Institute in St. Petersburg, an institution which was recently briefly described in the pages of THE LANCET.[1] He is a native of

FIG. 3.

Professor N. V. Skliffosowski, Joint President of the Organising Committee of the Congress.

the "government" of Kherson, and a graduate of the University of Moscow, and for the five years immediately succeeding his graduation was surgeon to one of the large municipal hospitals in Odessa. After spending some time abroad in visiting the surgical schools of Germany, France, and England, Dr. Skliffosowski returned to Russia, and soon obtained the Chair of Surgery in the University of Kief. Two years later he was transferred to the corresponding chair in the Army Medical Academy in St. Petersburg. This appointment he held for ten years, and during this period two great European wars

FIG. 4.

Professor I. F. Klein, Joint President of the Organising Committee of the Congress and President of the Executive Committee.

occurred—the Austro-Prussian War of 1866 and the Franco-Prussian War of 1870–71. In both cases Professor Skliffosowski went to the seat of war and took an active share in the campaigns. In the Russo-Turkish hostilities of 1877 he took a no less prominent part in the capacity of "consulting surgeon" to the army of occupation on the Danube. In 1879 he was appointed Professor of Clinical Surgery in the University of Moscow. During eight of his fourteen years' tenure of this chair he was also Dean of the Medical Faculty. In 1893 he was transferred, as already mentioned, to St. Petersburg. Professor Skliffosowski has the honourable

[1] THE LANCET, July 3rd, 1897, p. 35.

Digitized by Google

title of *Privy* Councillor, and he is the author of many monographs on surgical subjects.

Emeritus Professor Ivan Feodorovitch Klein, joint President with Professor Skliffosowski of the Organising Committee, and President of the Executive Committee of the Congress, is a native of St. Petersburg, but a graduate of Moscow. He finished his curriculum in the University of Moscow in 1861, and has never since broken his connexion with his *alma mater*. For three years he was assistant to the Professor of Pathological Anatomy; during 1864-69 he was prosector attached to the same chair; and since the year 1869 Dr. Klein has himself held this professorship. From 1869 to 1878 he was prosector in the hospital for suckling children attached to the great Foundling Hospital in Moscow; and for many years he filled the same post of prosector (or pathologist) to the Old Catherine Hospital, the hospital which formerly served as the University clinique. During 1870-78 Professor Klein was secretary to the Medical Faculty of the University of Moscow, and during 1878-80, and again from 1888 to the present time, he has been dean of this faculty. Professor Klein's published writings are numerous, and deal mostly with pathological subjects. Among them may be mentioned essays on "Thrombosis, Embolism, and Ichoræmia" (1863), on "The Etiology of Malignant Tumours" (1868), on "The Histology of Small-pox" (1869), on "Pelvis Spandylolisthetica Mosquensis" (1870), on "Hydrocephalus" (1871), on "Pericarditis" (1881), on "Disseminated Sclerosis" (1882), and many others. Professor Klein is also a Privy Councillor.

Professor Alexis Jacovlevitch Kojevnikof, Vice-president of the Organising Committee of the Congress, is a distinguished neurologist and alienist. A native of Riazan, Dr. Kojevnikof graduated in the University of Moscow in 1858. In 1860 he was elected assistant physician in the medical wards of the clinique, and three years later obtained a scholarship enabling him to carry on researches in the University laboratories and wards for a period of two years. In 1865 he took his M.D. degree, and in the following year was sent abroad at the charge of the University to spend three years in scientific work in other countries. He had already made the nervous system an object of special study, and in his three years abroad he worked under the first neurologists of the day in France, Switzerland, Belgium, Holland, and England. On his return to Russia he was appointed *privat-docent* in the nerve wards of the old clinique in Moscow. Neurology had at that time scarcely gained the position of an independent specialty, and Dr. Kojevnikof was the first professor of neurology appointed in any Russian university. When in 1884 the new university cliniques in

FIG. 5.

Professor A. J. Kojevnikof, Vice-President of the Executive Committee of the Congress.

Moscow were constructed the neurological and psychiatric wards were the first to be completed. In 1892 the Kojevnikof Neurological Museum in connexion with the cliniques was opened. It consists of a fine collection of anatomical and pathological preparations made by Professor Kojevnikof, and has been named after him. He was also instrumental in founding two large lunatic asylums—one of 400 beds, under the municipality of Moscow, and one of 600 beds, under the Moscow Government *zemstvo*. His influence as a teacher is shown by the fact that some years ago a small club was formed of the pupils and assistants of Professor Kojevnikof; and on the occasion of his twenty-five years "jubilee" the members dedicated to him a volume containing nineteen original essays on neurological subjects written by themselves. This club formed the nucleus of the "Moscow Society of Neuro-pathologists and Alienists," of which Professor Kojevnikof was elected the first president, an office which he still retains. He is a member of a large number of Russian medical societies and also of the Imperial Archæological Society, and a corresponding member of the Société Medico-Chirurgicale in Paris. His writings are numerous; they include observations on apbasia, lateral amyotrophic sclerosis, ophthalmoplegia, alcoholic paralysis, acromegaly, epilepsy, bulbar paralysis, and many other subjects (physiological, pathological, and clinical) connected with the nervous system. Many of his essays have been published in French and German as well as in Russian journals.

Professor Vladimir Karlovitch Roth, the general secretary of the Congress, is a native of Orel, and a graduate of Moscow, where he gained a gold medal for his prize essay upon Jaundice. He completed his curriculum in 1871, but remained in the university, working in the wards and laboratories of Professor Kojevnikof. Professor Roth had from the first devoted himself to the study of diseases of the nervous system, and in 1877 he went abroad for three years, visiting Paris, Berlin, and Vienna, hearing the lectures of the most renowned neurologists of the day, Broca, Claude Bernard, Charcot, Leyden, Frerichs, and others, and working in the laboratories of Vulpian and Virchow. In 1881 he was

FIG. 6.

Professor V. K. Roth, Secretary-General of the Congress.

appointed physician to the nervous wards of the Old Cathesine Hospital in Moscow; in 1891 he became assistant physician to the New Cliniques for Nervous Diseases; and in 1894 he was elected Extraordinary Professor of Neurology, the chair which he still holds. Professor Roth has published a large number of essays and observations on subjects connected with his speciality. In 1895 was published the first volume of his large and admirably illustrated work on "Progressive Muscular Atrophy," a subject which he has made his own, and upon which he has written a large number of articles and essays elsewhere. Lateral sclerosis, cerebro-spinal gliomatosis, acromegaly, myxœdema, neuralgia parsethetica, are some of the other subjects upon which Professor Roth has written, and in 1889 he described a new form of thermo-æsthesiometer in the pages of the *Progrès Médical*.

Professor Victor Vasilievitch Pashutin, as Director of the Army Medical Academy in St. Petersburg, and President of the Medical Council, fills two of the most honourable appointments obtainable in the profession in Russia. A native of Novotcherkask, in the territory of the Don Cossacks, he passed his student life in the Academy of which he is now the head. Even as a student his leaning towards the special

Digitized by Google

subject to which he afterwards devoted himself—namely, experimental physiology and pathology—began to show itself, and before he had qualified he published observations which he had made in the laboratories of the Academy. He obtained the title of *lékar* in 1868 and the degree of M.D. in 1870. In the following year he was sent abroad at the cost of the Academy to work in foreign laboratories for three years. His selection by the Academy for foreign travel was itself an honour of no mean kind; such selection is almost always the forerunner of a successful career, and in the majority of cases leads to a professorship in the future. Professor Pashutin worked principally while abroad under Ludwig and Huppert in Leipzig and under Hoppe-Seyler and Recklinghausen in Strasburg. During this period he published a large number of physiological observations, principally in German journals. In 1874 he was appointed Extraordinary Professor of General Pathology in the University of Kazan. In 1879 he was transferred to the corresponding chair in St. Petersburg, which he held until further promotion in 1890 compelled him to resign it. In 1885 he was appointed Scientific Secretary of the Academy, and in the same year he was elected a member of the council of the Ministry of Public Instruction, where his weighty advice, particularly upon matters relating to medical education, has often been of great service to the

FIG. 7.

Professor Victor Vassilievitch Pashutin, President of the Medical Council, and Director of the Imperial Academy of Military Medicine in St. Petersburg.

profession. In 1890 he was appointed by Imperial command to the office of *Natchalnik* (Principal or Director) of the Army Medical Academy, an appointment which he still retains. In 1889 Professor Pashutin was elected a member of the Medical Council, the highest authority upon medical matters in the country; and in December of the same year he was named by Imperial command the President of the Council in succession to the late Dr. Zdekauer. He is honorary member of a large number of Russian medical societies in all parts of the empire. In 1896 he received the title of Privy Councillor. Professor Pashutin has been the recipient of several orders—the Stanislas of the First Class, the St. Anne of the First Class, and the Montenegrin order of Prince Danilo I. At the last two International Medical Congresses he has been the President of the Russian National Committee, and he is a member of the Organising Committee of the present Congress. Professor Pashutin's published works include two volumes of "Lectures on General Pathology" (1878 and 1881); a large and valuable work entitled, "Course of General and Experimental Pathology," two volumes of which have been issued, and which he hopes to complete this autumn; and some ninety essays and articles on many physiological and pathological subjects.

Professor Niel Feodorovitch Filatof, the treasurer of the Congress, is a native of Penza. He graduated in the University of Moscow in 1869. After spending some years abroad in Vienna and Prague he returned to Russia and devoted himself entirely to the subject of diseases of children. In 1876 he was appointed *privat-docent*, and in 1891 Professor of Pediatrics in the University of Moscow, and this chair he still holds. Professor Filatof's writings include a volume on "The Semeiology and Diagnosis of Diseases of Children," which has had four Russian editions

FIG. 8

Professor N. F. Filatof, Treasurer of the Congress.

and been translated into German, Hungarian, Czech, and Italian; "Infectious Diseases in Children"; a "Manual of Children's Diseases," which has reached a third edition; "Diseases of the Digestive Tract in Children"; and many other contributions to the subject of pediatrics.

Professor Peter Ivanovitch Diakonof, one of the secretaries of the Congress, was born in Orel, and is a graduate of the Army Medical Academy in St. Petersburg. In 1888 he was appointed *privat-docent* to the chair of Operative Surgery and Topographical Anatomy in the University of Moscow, and in 1893 was elected to the professorship in this subject. Professor Diakonof is also consulting surgeon to several of the large general hospitals in Moscow; he is president of the Moscow Surgical Society; editor of *Chirurgia*, a monthly magazine devoted to the subject which gives it its title; and author of many essays and observations upon surgical subjects.

We hope that the foregoing brief biographical notices of the organisers of the Moscow Congress will be of interest to our readers. Next week we shall issue a special and very fully illustrated supplement dealing with the History, past and present, of Medicine in Russia.

ADMISSION OF THE PRINCE OF WALES TO THE HONORARY FELLOWSHIP OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

WE have received the following official account of the proceedings at Marlborough House on July 19th, on the occasion of the admission of H.R.H. the Prince of Wales to the Honorary Fellowship of the Royal College of Physicians of London, which we have much pleasure in publishing. In reference to our remark, in a leading article last week on the subject, that "it had been an open secret in medical circles for some weeks that His Royal Highness might soon be expected to become a member of our profession by accepting a diploma from the College," it is now publicly stated that the Prince of Wales's election dates from a Comitia held on April 29th of this year.

The President (Sir Samuel Wilks, Bart.), the four Censors (Dr. Church, Dr. Cayley, Dr. Bastian, and Dr. Payne), the Treasurer (Sir Dyce Duckworth), and the Registrar (Dr. Edward Liveing) attended by appointment at Marlborough

Digitized by Google

House in their College robes, accompanied by the Bedell with the College insignia.[1]

On the entrance of the Prince, after the officers had been presented to him, the President addressed His Royal Highness as follows:—

"Sir,—We, the President and principal officers of the Royal College of Physicians, have assembled here, in compliance with an intimation received of your Royal Highness's pleasure, to admit you to the Honorary Fellowship of our College, which you have been graciously pleased to accept.

"In fulfilment of my duty as President, and in accordance with the usage of the College, I have to ask your Royal Highness to give your assent to a declaration, which is in these terms: 'You give your faith that you will, as far as in you lies, maintain the honour and defend the rights of the College unimpaired.'"

The Prince willingly gave his assent, and then subscribed his name to the same form of words inserted in the Register of Fellows.

The President, again addressing His Royal Highness, formally admitted him a Fellow in the following words: "I, Samuel Wilks, President of the Royal College of Physicians of London, admit your Royal Highness Albert Edward, Prince of Wales, to the Honorary Fellowship of our College"; and, taking the Prince's hand, wished him "all happiness" in the name of the College.[2]

The Prince was then presented with a diploma on vellum, illuminated with the College arms, contained in a case of red morocco, and with a gold-headed cane, after the fashion of those formerly carried by physicians, with a vinaigrette in the head to ward off infection. These were graciously accepted and courteously acknowledged by His Royal Highness.

The following is the text of the diploma:—

SCIANT OMNES NOS,

SAMUELEM WILKS, Baronettum, Medicinæ Doctorem et Præsidentem Collegii Regalis Medicorum Londinensis, una cum consensu Sociorum ejusdem Collegii, auctoritate nobis a Domino Rege et Parliamento concessa, in Societatem nostram, honoris causa, cooptasse virum illustrissimum ALBERTUM EDVARDUM, Walliæ Principem, Cornubiæ Ducem, Nobilissimi Ordinis Periscelidis Equitem. In cujus rei fidem et testimonium Sigillum nostrum Commune præsentibus apponi fecimus.

Datum Londini in Collegio nostro die vicesimo nono mensis Julii, annoque Domini Millesimo octingentesimo nonagesimo septimo.

The President then addressed the following concluding words to the Prince: "And now, with your Royal Highness's permission, I should like to add a few words to my formal duties. Standing here as the representative of this ancient and learned body, I desire to assure your Royal Highness that the announcement of your willingness to join our Fellowship was received with the greatest enthusiasm and satisfaction by the Fellows. For remembering, as we do, that our College received its first Charter from the hands of King Henry VIII., and that the illustrious Harvey, who may be regarded as its second founder, was on terms of friendship with King Charles I.; and that during the two centuries which followed our annals show the close connexion which existed between many of our eminent Fellows and the Royal Family, until we reach the time when, through the influence of our President, Sir Henry Halford, with King George IV., the site of the present College was secured to us from the Crown; and that on the completion of the edifice its inauguration took place under the auspices of the Royal family, the Duke of York, accompanied by the other Royal dukes his brothers, being present on the occasion, and the King graciously conferring that day on our President the star of a Knight Commander of the Order of Hanover,—when we recall, I say, all those events it must be evident to your Royal Highness with what satisfaction the College sees that there is no abatement in the kindly feeling which has ever been shown towards us by the Royal Family, but that it is perpetuated by your illustrious name being now enrolled in our annals."

The Prince in courteous terms expressed the pleasure it gave him to be connected with so ancient and honourable a corporation, and then took leave of the President and officers.

[1] The mace and cushion; the College statutes, bound in velvet, with the Corporation seal attached; and the caduceus of Dr. Caius.

[2] The "omnia fausta precor" of the old Latin form.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

AN exhibition of very general interest to the profession was opened this week in the Queen's Hall, Langham-place. Those who are responsible for this departure—and the committee includes the names of some of the leading druggists and surgical instrument makers—must be congratulated on the success which, judging from the excellent number of visitors present during the week, has attended their first venture. The Queen's Hall does not afford very much space for the arrangement of exhibition stalls, but although the exhibition could not be regarded as a very large one, yet it contained an admirable selection of drugs, sanitary appliances, surgical instruments, &c., with the improvements of which an exhibition of this sort affords the practitioner an excellent opportunity of becoming acquainted.

In the exhibits which we may classify under the section of drugs Messrs. Oppenheimer, perhaps, displayed the greatest variety of specimens. The exhibit included a most interesting collection of medical, surgical, and pharmaceutical antiquities lent to the association by Mr. William Oppenheimer. The collection comprised surgical instruments and terra-cotta votive offerings of ancient Italy, the instruments dating from the first to the fifth century. The collection also included a series of forty-three different implements found in the tomb of an "oculist," and there was also on view a large collection of ancient drop bottles, invalid cups, and feeding bottles, many of these being of Etruscan make. These were in curious contrast to the fine pharmaceutical products for which this firm is well known, the feature of the exhibit being, of course, the palatinoid and bi-palatinoid, which are of special service in administering unstable and nauseous drugs and the animal extracts. In Messrs. Warwick Brothers' small but interesting exhibit the chief thing shown was the iron "jelloid," in which, as we have found, the iron is preserved intact in the ferrous state, so that the jelloid presents an excellent and reliable form of Blaud pill. Mr. B. Kühn's exhibits included the new non-poisonous, non-irritant, yet powerful antiseptic, disinfectant, and deodorant, chinosol; anti-diphtheritic serum (Ruete-Enoch); tannalbin, ferropyrin, papain, diuretin, and ethyl chloride in handy metal cylinders for inducing local anæsthesia. Messrs. Potter and Sacker presented a very pretty exhibition, including Schieffelin's perfect pills, which are well-known for their general pharmaceutical excellence, solubility, and yet permanency of character. The exhibit included various suppositories and a well-prepared syrup of hydriodic acid. Messrs. Arthur and Co. showed some interesting new pharmaceutical additions. Of these might be mentioned extractum radicis pernionis, a preparation for the treatment of chilblains, itching, and bruises; a neutral non-saccharine fluid containing lime and iron, which is said to obviate the disagreeable effects of ordinary iron salts; iodoglycerol; and the following iodine preparations which are said not to produce iodism—iodotannin, iodogelatin, iodovitellin, and iodoalbumin. Messrs. Hockin, Wilson and Co.'s exhibit included their well-known special pharmaceutical preparations, amongst which should be mentioned the excellent combinations of podophyllin with pepsin or belladonna with strychnine. Excellent specimens of pharmaceutical advance were illustrated in the exhibit of Messrs. Kirby and Co. in the various kinds of pills coated with "pearl," sugar, gelatin, gold, and silver. An enormous assortment of extracts, tablets, and drugs was displayed on the stall of Messrs. Parke, Davis, and Co., while the feature of Messrs. Cooper and Co.'s exhibit was the pretty cachets, which consist of flexible, tasteless, and easily soluble wafer capsules for the administration of drugs. Mr. Martindale's stall gave evidence of his determination to keep pace with modern requirements. Of the novelties in Messrs. J. F. MacFarlan and Co.'s exhibits should be mentioned the silk sutures and catgut ligatures, the latter being put up in the form of balls, as suggested by Dr. Charles Cathcart. The exhibit, of course, included this firm's well-known purified chloroform. Close by was a display of certain members of the aromatic series, by the Fleming's Oil and Chemical Company, and chiefly those employed as antiseptics and insecticides. It included ammoniated camphylene cream, moth preventives, and various carbolic preparations.

The bulk of the displaying space was undoubtedly devoted

Digitized by Google

to surgical appliances and instruments, and this section attracted considerable interest. No less than twenty-one firms contributed to this collection. They included Messrs. Maw, Son, and Thompson, of 7 to 12, Aldersgate-street, E C. (aseptic instruments, clinical thermometers, syringes, india-rubber goods, &c.); Messrs. Claudius Ash, and Sons, Limited, of 5 to 9, Broad-street, Golden-square, W. (dental requisites, nitrous oxide gas appliances, &c.); Messrs. Mayer and Meltzer, of 71, Great Portland-street (gynæcological instruments and aseptic appliances); Messrs. John Weiss and Son, of 287, Oxford-street, W. (aseptic instruments, operating tables, &c.); Messrs. K. R. Schramm and Co., of 24, Great Castle-street, W. (orthopædic appliances); Messrs. John Bale, Son, and Danielsson, of Great Titchfield-street, Oxford-street, W. (anatomical diagrams, clinical figures, &c.); Messrs. Evans and Wormull, of 31, Stamford-street, S.E. (army medical equipments); Mr. W. K. Stacy, of 4, Newgate-street, E.C. (various hospital accessories); Mr. K. Schall, of 55, Wigmore-street, W. (electrical apparatus, including that for the x-ray work); Messrs. J. G. Ingram and Son, of Hackney Wick (rubber goods, enemas, syringes, &c.); the Lattice Elastic Stocking and Mavette Co., of 70, Fenchurch-street, E.C. (varicose vein appliances, chest protectors, and binders); Miss Webb, of Bournemouth (hospital and massage gown obviating movement on the part of the patient and useful in surgical cases); Messrs. Coxeter and Son, of Grafton-street, Gower-street, W.C. (gynæcological instruments, anæsthetics, inhalation and electrical apparatus); Mr. Frank A. Rogers, of 327, Oxford-street, W. (sprays, anatomisers, and injecting apparatus); Messrs. T. Burberry and Sons, of 30, Haymarket ("urber," a mackintosh substitute); Messrs. Down Brothers, of 21, St. Thomas's-street, S E. (every conceivable form of surgical instrument); Messrs. C. J. Plucknett and Co., of 25, Poland-street, Oxford-street, W. (dental appliances); Messrs. W. H. Bailey and Son, of 38, Oxford-street, W. (surgical instruments, enemas, douches, bed-pans, ear-trumpets, &c.); Messrs. Nehmer Brothers, of 27, Sekforde-street, Clerkenwell, E.C. (new electrical apparatus to take the place of batteries for medical purposes); Messrs. T. J. Syer and Co., of 45, Wilson-street, Finsbury-square (operating table and couch, and invalid accessories); and Mr. F. Davidson, of 120, Great Portland-street (simple sight-testing apparatus for the general practitioner).

Sanitary appliances were well and widely represented. One of the most interesting exhibits coming under this classification was that of Messrs. J. Defries and Sons, Limited, of 147, Houndsditch, E.C., who illustrated the application of the Pasteur filter both on the small and large scale. The exhibit, in addition, comprised the Equifex saturated steam disinfector, steam sterilisers, and some cultures of pathogenic organisms. Some good things were shown by the Liverpool Lint Co., of Netherfield-road (North), Liverpool, amongst them being flax and cotton lints, bandages, carbolised tow, and "first-aid" dressings. Messrs. S. F. Goss, Limited, of 201, Regent-street, showed a high-class collection of toilet appliances and preparations adapted to modern medical requirements, and which they describe as "free from quackery." Close by was the stall of the Sanitary Wood Wool Co., of 26, Thavies-inn, Holborn-circus, E.C., where Hartman's patent wood wool preparations could be inspected. These, as is now well known, are applied for all conditions wherever antiseptic treatment is needed. Messrs. Tidman, Son, Limited, brought to the notice of the visitors their sea salt, sea soap, salicylic soap, and creamoline soap. The Lawes Chemical Co., of 59, Mark-lane, E.C., displayed to advantage their comparatively non-poisonous disinfectant fluid, which neither stains nor burns. Other disinfectants were shown, as, for instance, formalin, by the Formalin Hygienic Co., of 9 and 10, St. Mary's-hill, E.C., which may now be applied in various forms for all purposes of disinfection and sterilisation. The more well-known and time-honoured disinfectant, chlorine, was shown in improved form as bleaching powder by the United Alkali Co., of Exchange-buildings, Liverpool. Their preparations are a great advance on the old bleaching powder. The interesting absorbent material now prepared from peat by the Peat Industries Syndicate, of 15, Walbrook, E.C., was shown in various hygienic forms, as, for example, accouchement sheets, dressings, sanitary towels, &c. The great advantage of this eminently absorptive material is that in itself it is distinctly clean as well as antiseptic. The Whitely Exerciser Co., Limited, of 20 and 21, Laurence Pountney-lane, Cannon-street, E.C., exhibited an ingenious little contrivance providing an infinite variety of exercises and adapted for exercising in a small space; it may even be used by bed-fast patients. Messrs. D. Blair and Co., of 47, Cannon-street, E.C., showed their "Instra" Warmers, which are very handy and convenient for all purposes of local warming; they have already been accorded a favourable account in our columns. "Autosprays" are the patented invention of the Medico-Hygienic Inventions Company, Limited, of 63, Queen Victoria-street, E.C., which are well worthy of mention. These consist of solutions of a variety of remedies, agents for immediate application, in the form of a fine spray. In this exhibit also Trillat's system of aerial disinfection was illustrated, and preparations suitable for use in the system were shown. The comparatively rapidly-acting yet sterilising filter of the Berkefeld Filter Company, of 121, Oxford-street, W., was shown in action, and afforded an attractive exhibit. Messrs. Newton, Chambers, and Co. displayed several Izal preparations, the active constituent, though a powerful antiseptic, being otherwise quite innocuous. Lastly, Messrs. Ewart and Sons, of 346, Euston-road, N.W., gave an excellent demonstration of the advantages of their "Geyser," which, as was shown, could be applied for all domestic purposes.

(To be concluded.)

THE HOSPITAL REFORM ASSOCIATION.

THIS youthful though energetic association held its first annual dinner at the Holborn Restaurant on July 26th, Dr. WARD COUSINS being in the chair. Some sixty members and others interested in hospital reform were present.

In proposing the toast of the Hospital Reform Association Mr. LOCH referred to the fact that the staffs of hospitals were not sufficiently in touch with the outside practitioners. If all the organisations and societies in a given district knew what they were severally doing, and could communicate the one with the other, it would go far to eliminate some of the worst instances of hospital abuse. In a great many instances he thought that out-patients should, after having been seen once, be referred back to their usual medical man.

The Chairman and other members, in responding to this toast, all laid stress upon the lack of supervision of out-patients as to whether or not they were fit subjects for relief. Although in many instances the general practitioner abused the hospital by sending patients to a hospital to save himself trouble, yet a great part of the blame lay with the staffs of hospitals who saw any patient who might come without inquiry.

Dr. GLOVER thought the abuse of hospitals one of the most serious questions now before the public and perhaps the most serious one before the profession. In various relations he had had to study it. As a member of the Council of the Metropolitan Hospital Sunday Fund he had directed attention to it and would continue to do so, for it was still undisposed of in that body. He was at the meeting that night as the representative of THE LANCET, whose deep interest in the question was shown by a series of investigations which had more than anything else set the truth on this subject before the profession and the public. The medical profession had a deep interest in the right administration of medical charity, for the profession itself, apart from hospitals, did half the medical charity of the country. Finally, he impressed on the association that their success must depend on securing the support of the united profession. They, as general practitioners, could not act efficiently without the help of the medical staffs, for without their aid hospitals could not be conducted, and their interests could not be separated from those of the profession at large.

Mr. TIMOTHY HOLMES mentioned that he was, perhaps, the only surviving member of a committee which sat in 1871 to consider the question of hospital abuse. There were a number of eminent persons upon it, and they did—nothing. He thought that every hospital should be restricted to its own district and be a great centre of charity for that district; it should be in touch with the general practitioners in the neighbourhood, and they should be able to look

Digitized by Google

upon it as a centre whence advice and help could be obtained. Such a scheme, he thought, would be of benefit to both patient and medical man. With regard to the abuse of the letter system, that had been given up at St. George's Hospital for the last thirty years.

The proceedings ended with the usual complimentary toasts. A notable feature of nearly all the speeches was the number of complimentary references to the work done by THE LANCET in its inquiry into club practice and the like. It was cheering too to see how men from the provinces as well as metropolitan medical men were all agreed as to the necessity of in some manner curbing hospital abuses. We can only wonder how it is that this evil has been allowed to attain to such proportions not only under the eye of the profession, but with its very connivance and assistance; but the fact is obvious. Men holding hospital appointments and more or less represented on the managing boards of hospitals have looked passively on while the canker of abuse has grown until it almost defies control, and it has become a difficulty now to convince hospital authorities that there is any evil to be remedied. Familiarity breeds contempt, and they have become so accustomed to crowds of patients as to regard them as a credit and ornament to their respective hospitals. Such crowding leads to the very evils which are rightly complained of as being present in club and medical aid societies' practice. Careful observation, discrimination of cases, and the personal factor are all wanting and impossible in the presence of such numbers of patients, so that cases that need help, and further help than mere medical attendance, cannot be particularly attended to. This is the very discredit of a charitable institution, to invite a promiscuous crowd, pauperising the well-to-do, and not extricating from pauperism the really poor. The present year is likely either to fasten this curse of hospital pauperism on the public and the profession with a tight grip or to see a change in the administration of hospitals. The whole profession is interested in seeing this change effected without delay, and can either compel the reform, leaving intact all that is good in the hospital system, or it can, by apathy and divided counsels, give the evil a fresh lease of existence.

THE INTERNATIONAL CONGRESS OF NEUROLOGY, PSYCHIATRY, MEDICAL ELECTRICITY AND HYPNOLOGY.

THE first session of this Congress will be held at Brussels from Sept. 14th to 19th, 1897, under the presidentship of Professor Verriest of Louvain. The general secretary is Dr. Crocq, of the Molenbeek Hospital, whose address is 27, Avenue Palmerston, Brussels. All authors of personal contributions are requested to send a summary of their contributions to the general secretary as soon as possible. We subjoin the official programme so far as it has been at present decided.

QUESTIONS SUBMITTED FOR DISCUSSION.

NEUROLOGY.

I. The Surgical Treatment of Epilepsy: its Indications and Consequences. Reporter: Professor Winkler, of Amsterdam (Holland).

II. Pathogeny and Treatment of Exophthalmic Goitre. Reporter: Professor Eulenburg, of Berlin (Germany).

III. Pathogeny and Semeiology of Reflexes. Reporter: Professor Mendelssohn, of St. Petersburg (Russia).

IV. (Subject not yet decided.) Reporter: Professor Oppenheim, of Berlin (Germany).

V. Influence of the Delivery on the Nervous and Mental Diseases presented later by Children. Reporter: Professor Anton, of Graz (Austria-Hungary).

VI. Pathogeny of Muscular Rigidity and of Contracture in the Organic Affections of the Nervous System. Reporter: Professor Van Genuchten, of Louvain (Belgium).

PSYCHIATRY.

I. On the Diagnostic Value of the Prodromic Symptoms which long Precede the Manifestations of General Paralysis. Reporter: Professor Thomson, of Bonn (Germany).

II. Psychoses and Dreams. Reporter: Dr. Sante de Sanctis, of Rome (Italy).

III. On the Modifications of the Morbid Type of Progressive Paralysis of the Insane during the last Thirty Years. Reporter: Professor Mendel, of Berlin (Germany).

IV. On the Relations between Psychoses, Mental Degeneration, and Neurasthenia. Reporter: Dr. Lentz, of Tournai (Belgium).

MEDICAL ELECTRICITY.

I. The Semeiological Value of Electrical Reactions of Muscles and Nerves. Reporter: Professor Doumer, of Lille (France).

II. The Therapeutical Value of High Frequency Currents. Reporter: Professor Bergonié, of Bordeaux (France).

HYPNOLOGY.

I. The Therapeutical Value of Hypnotism and Suggestion. Reporter: Dr. Milne Bramwell, of London (England).

II. The Question of Criminal Suggestions: their Origin and Actual State. Reporter: Professor Liegeois, of Nancy (France).

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6543 births and 4060 deaths were registered during the week ending July 24th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 14·7 to 16·6 per 1000, further rose last week to 19 3. In London the rate was 20·0 per 1000, while it averaged 18·8 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·1 in Derby, 10·3 in Croydon, 10·9 in Swansea and in Halifax, and 12·8 in Huddersfield; the highest rates were 22·5 in Birmingham, 24 9 in Salford, 25·3 in Sheffield, and 26·4 in Liverpool. The 4060 deaths in these towns included 904 which were referred to the principal zymotic diseases, against 504 and 572 in the two preceding weeks; of these, 526 resulted from diarrhœa, 153 from measles, 92 from whooping-cough, 60 from diphtheria, 48 from scarlet fever, 25 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases was recorded last week in Halifax; in the other towns they caused the lowest death-rates in Brighton, Swansea, and Derby; and the highest rates in Salford, Portsmouth, Sheffield, and Preston. The greatest mortality from measles occurred in Birmingham, Manchester, Burnley, Salford, and Preston; from whooping-cough in Oldham, Sheffield, and Sunderland; and from diarrhœa in Leicester, London, West Ham, Portsmouth, Liverpool, Birkenhead, and Sheffield. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 60 deaths from diphtheria included 42 in London, and 4 in Liverpool. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no cases of small-pox were under treatment during the week in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2976, against numbers increasing from 2380 to 2903 on the twelve preceding Saturdays; 396 new cases were admitted during the week, against 310, 349, and 381 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 116 and 138 in the two preceding weeks, further rose last week to 158, but were 22 below the corrected average. The causes of 58, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Oldham, Leeds, Hull, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Norwich, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7 and 17·9 per 1000 in the two preceding weeks, further rose to 19·5 during the week ending July 24th, and slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·8 in Aberdeen and 15·2 in Greenock to 23·9 in Perth and 25·6 in Leith. The 580 deaths in these towns included 37 which were referred to whooping-cough, 35 to diarrhœa, 15 to measles, 7 to "fever," 5 to scarlet fever, and 1 to diphtheria. In all, 100 deaths resulted from these principal zymotic diseases, against 82 and 80 in the two preceding weeks. These 100 deaths were equal to an annual rate of 3·4 per 1000, which was 0·9 below the mean rate last week from the same diseases in the thirty-three large English towns. The 35 fatal cases of diarrhœa showed a further increase upon the numbers recorded in recent weeks, and included 20 in Glasgow and 7 in Dundee. The deaths referred to whooping-cough, which had increased from 16 to 23 in the three preceding weeks, further rose to 37 last week, of

Digitized by Google

which 19 occurred in Glasgow, 7 in Edinburgh, and 6 in Dundee. The 15 fatal cases of measles exceeded by 3 the number in the preceding week, and included 8 in Leith, 4 in Glasgow, and 3 in Edinburgh. The deaths referred to different forms of "fever," which had been been 10 and 3 in the two preceding weeks, rose again to 7 last week, of which 2 occurred in Glasgow, where 3 of the 5 fatal cases of scarlet fever were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 69 and 68 in the two preceding weeks, rose again to 87 last week, and exceeded by 21 the number in the corresponding week of last year. The causes of 38, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 20·3 to 24·2 per 1000, declined again to 23·3 during the week ending July 24th. During the past three weeks of the current quarter the death-rate in the city has averaged 23·0 per 1000, the rate during the same period being 17·1 in London and 20·2 in Edinburgh. The 156 deaths registered in Dublin during the week under notice showed a decline of 6 from the number in the preceding week, and included 20 which were referred to the principal zymotic diseases, against 9 and 11 in the two preceding weeks; of these, 7 resulted from diarrhœa, 4 from whooping-cough, 3 from measles, 3 from diphtheria, 2 from scarlet fever, and 1 from "fever." These 20 deaths were equal to an annual rate of 3·0 per 1000, the zymotic death-rate during the same period being 4 6 in London and 2·8 in Edinburgh. The 7 fatal cases of diarrhœa considerably exceeded the numbers recorded in recent weeks. The deaths referred to whooping-cough, which had been 2 and 3 in the two preceding weeks, further rose to 4 last week. The mortality from "fever" showed a decline, while the deaths from measles, scarlet fever, and diphtheria exceeded those recorded in the preceding week. The 156 deaths registered in Dublin last week included 33 of infants under one year of age, and 35 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons were slightly below those recorded in the preceding week. Six inquest cases and 2 deaths from violence were registered; and 54, or more than a third, of the deaths occurred in public institutions. The causes of 7, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR E. D. FARMAR-BRINGHURST has been given the Medical Charge of the Northumberland Artillery Militia during the stay of the corps at Plymouth. Surgeon-Captain H. I. Pocock proceeds to Horfield for duty, and Surgeon-Lieutenant Marriott assumes Medical Charge of troops, South Fort Barracks, Dover. Brigade-Surgeon-Lieutenant-Colonel J. M. Beamish, M.D., joins at Woolwich for duty, and Surgeon-Major W. T. Johnston proceeds to Okehampton for Medical Charge of the camp. Surgeon-Major Patrick J. O'Sullivan, M.D., retires from the service receiving a gratuity. Surgeon-Major Patrick Halion Fox, M.R.C.S.I., retires from the service receiving a gratuity.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the under-mentioned officers are replaced at the disposal of the Government of India, Home Department: — Surgeon-Captain C. D'Alton, A.M.S., Surgeon-Captain J. F. Kelly, A.M.S., Surgeon-Major Routh, A.M.S., and Surgeon-Captain Mangan, A.M.S. The services of Surgeon-Lieutenant J. C. Robertson, on plague duty in the Jhansi districts, are replaced at the disposal of the Government of India, Home Department.

NAVAL MEDICAL SERVICE.

Surgeons: Richard W. Stanistreet to Chatham Hospital; James Bradley, M.D., to the *Egeria;* and Daniel J. P. McNabb to Haslar Hospital.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major George W. Hatchell, having resigned his Militia appointment, ceases to belong to the Army Medical Reserve of Officers. Surgeon-Captain C. C. Moxon, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 6th Lancashire: Surgeon-Lieutenant W. H. Murdoch, M.D., resigns his commission. 1st Argyll and Bute: Surgeon-Captain J. Cunningham, M.B., resigns his commission. *Rifle:* 1st Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Lieutenant-Colonel T. M. Dolan, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 3rd Glamorgan: Surgeon-Lieutenant J. E. J Soden resigns his commission. 1st Tower Hamlets: Surgeon-Lieutenant J. F. Woods, M.D., resigns his commission.

THE ALLEGED COMING CHANGES AT THE HORSE GUARDS.

There has of late been a good deal of discussion in the public journals regarding the rumoured changes at the War Office, but owing to some quasi-official assurances matters appear to have settled down for the present. The discussion was raised, we suspect, more with the view of registering a protest against the accomplishment of certain alleged appointments than with any belief that these had actually been definitely agreed upon. The *Saturday Review* of the 10th inst. had a paragraph, *à propos* of the rumours that Lord Wolseley's health was not good, and might lead to his resigning the supreme command of the army, in which it admitted a feeling of disappointment of the hopes entertained on his being appointed to that office. As regards the appointment hereafter of a Royal Duke to the position our contemporary remarked that it would probably lead to its being made permanent, which, as experience had shown, is to stereotype inefficiency. In case of the rumoured retirement of Lord Wolseley turning out to be correct — it is but a rumour and most probably an unfounded one—Lord Roberts's great claims would, of course, have to be considered. Amid the various statements, however, that have been put forward of late only one thing seems certain—namely, that the post of Adjutant-General of the army will have to be filled up in October on the retirement of Sir Redvers Buller, but nothing is definitely known at present as to who his successor will be. The general feeling in the army appears to be that Sir Evelyn Wood, the present quartermaster-general, has the greatest claims to be Sir Redvers Buller's successor. He has had, as everybody knows, a long, distinguished, and very varied service as a soldier, and is besides a very practical, straightforward, and able man. In the event of his appointment the question arises as to who is to be the new quartermaster-general? Apart from difficulties arising out of his Royal rank and political considerations, it is only just to say that the Duke of Connaught is very popular, has a keen love of his profession, is a good man of business, and is most conscientious and painstaking in the discharge of his duties. His Royal Highness has impressed people, too, as being eminently fair and conciliatory to all. The nation as a whole and all branches of the service are necessarily interested in these appointments, for the efficiency as well as the contentment and happiness of the army, and of the medical service as an important branch of it, greatly depends upon the wisdom of the choice. The retiring Adjutant-General, Sir Redvers Buller, is universally regarded as an able and honest man, and a most distinguished soldier, of whom more will be heard in the event of any war occurring.

ARMY SERVICE IN INDIA.

Captain Pirie asked the Under-Secretary for War in the House of Commons on the 23rd inst. whether the War Office would be prepared to reconsider the question of long service in India for British troops as being both physically and financially advantageous, especially in view of the disastrous casualties from enteric fever and other disease among British soldiers in India.—Mr. Brodrick said, in reply, that the application of the short-service system to India has been proved to possess many advantages from a physical, financial, and military point of view, and Her Majesty's Government had no intention of resorting to the system of long service in the Indian army. We have frequently adverted to this subject in the past. It appears that the amount of sickness, and notably of enteric fever, is much greater among young soldiers during their first two years of service in India than among older and

Digitized by Google

longer resident soldiers, but the death- and invaliding-rates are greater among the latter. A soldier of about twenty-five years of age, and from that to thirty, with over two years' service in India, is probably at his best for military purposes and efficiency. On medical and physical, and consequently on financial, grounds it seems to us that no pains should be spared to retain soldiers for Indian service for a few years—at any rate, for a year or two—longer in India than at present; but we suppose it is argued that this would interfere with the working integrity of the present short-service system.

THE LATE GRECO-TURKISH WAR.

We can commend the perusal of Mr. Bennet Burleigh's article on "The Greek War, as I Saw It," published in the *Fortnightly Review* for this month to those who are interested in the subject. The article is the reverse of flattering to the Greeks. It certainly gives an object-lesson on the text "How war should not be made." Mr. Bennet Burleigh says that while at Salonica he ascertained, through an English friend who had made it his business to know, and from personal observation, that 12,000 sick and wounded Turkish soldiers had been brought into that place from Thessaly. These did not include all the worst cases or those who were wounded in the later engagements, such as those of the last days around Velestino and Domoko.

THE CHITRAL AFFAIR.

We are always having some little mountain warfare on hand in India. The intelligence that has been received at the India Office regarding the night attack on the British force by the hill tribes in the Malakand Pass, resulting in the death of one and the wounding of four officers, is embarrassing news for the Indian Government, because it involves the trouble and cost of a punitive force. Moreover, it is very difficult to guard against such attacks in the future or to deal effectively with those taking part in them. One thing is clear, that the strength of the Indian Medical Service must be maintained in order to supply medical officers to meet contingencies of this kind.

THE ARMY MEDICAL STAFF.

It appears that the War Office will not obtain a sufficient number of candidates to fill the vacancies existing in the British Medical Service at the forthcoming examination. It is calculated that at least forty or fifty vacancies have to be filled and, according to the latest official statement in the House of Commons, there were a little time ago only twenty-seven candidates for these appointments.

ARMY MEDICAL SCHOOL, NETLEY.

The summer session of the Army Medical School, Netley, will be brought to a close on July 30th, when the names of those gentlemen recommended for commissions in the Army Medical Staff and Indian Medical Service will be announced and the prizes will be distributed by Major-General Sir William Butler, K.C.B., commanding the South-Eastern District.

THE HEALTH OF BOMBAY.—The news from Bombay is not altogether satisfactory. There has ceased to be any mortality from plague, but there is some cholera in the city, and the death-rate is still high.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting, under the auspices of the Incorporated Society of Medical Officers of Health, was held in Bristol on July 24th. The members were received at the Guildhall by the High Sheriff of Bristol and the chairman of the Bristol Sanitary Committee. A business meeting was held, and, after partaking of luncheon at the invitation of the latter gentleman, the members proceeded to Ham-green for the purpose of inspecting the fever hospital in course of erection there.

PRESENTATIONS TO MEDICAL MEN.—Mr. G. H. Ede, M.D., C.M.Aberd., of Bramley, Surrey, has been the recipient from the Bramley classes, in connexion with the St. John Ambulance Society, of a walking stick with silver mountings from the men's class, and a paper knife with silver handle from the women's class, as thank-offerings for his ambulance lectures.—Mr. Thos. F. Fannahill, M.B. Glasg., D.P.H. Camb., of Glasgow, has been presented by twenty-two members of the Caledonian Medical Society with a Morton's Ophthalmoscope and accessories, appropriately inscribed. Until recently he was the editor of the *Caledonian Medical Journal*, and is now proceeding to South Africa.

Correspondence.

"Audi alteram partem."

THE RINDERPEST.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 6th you were kind enough, in reviewing Dr. Koch's report of Jan. 31st, to refer to the correspondence I had with the Government. I now send you a memorandum embodying the suggestions that have been made from time to time by me and the results arrived at by the various experts arranged in chronological sequence, and as I thought the views expressed were original, although further reading shows that not to be the case, it is hoped that you will be able to find space for the document, and if you think it worthy of editorial comment you may be able to get me a hearing and enable me to endeavour to avert a calamity. Although not entirely original, you will see doubtless the application of my ideas to many human diseases; its application to the bubonic plague was suggested to the Indian Government on Feb. 8th and 10th. When my views were submitted to the Government expert they were condemned, and in consequence it was not possible for me to get a hearing before the Select Committee. Meanwhile the disease is spreading rapidly into the colony, and I much fear will become endemic if Dr. Hutcheon's view be carried out.

Within the last few days a method has been thought out whereby the toxic strength of the blood might be increased, but until Dr. Edington's annual report appears I shall not know whether I am trespassing on his preserves, so at present do not like to mention it.

I am, Sirs, yours faithfully,

Sea Point, June 8th, 1897. H. A. LAWRANCE, F.I.C., F.C.S.

MEMORANDUM.

1. Oct. 22nd, 1896.—Letter to Mr. Farre. Suggests the use of blood of "salted" cattle as a preventive method.

2. Oct. 26th, 1896.—Letter to Secretary, Rinderpest Committee, Bloemfontein, O.F.S. Points out that suggestion in Par. 1 anticipates the work of bacteriologist, as after discovery and isolation of organism he would have to prepare the antitoxin. "The antitoxin is, I believe, undoubtedly present in the blood of beasts that have survived the disease."

3. Nov. 7th, 1896.—Letter to Dr. Edington. Suggests the use of blood of "salted" cattle as a preventive method.

4. Nov. 10th, 1896.—Letter to Mr. Farre. "Blood might be drawn off from the animal (salted) and filtered through a porcelain candle in order to obtain the serum. If it be that there has been a change in the blood with the production of a toxin or antitoxin, then this serum should have a protective action."

5. Nov. 29th, 1896.—Letter to H.E. the Governor: "Bearing this in mind, it occurred to me that one or other of two things must have taken place in the blood of these immunised cattle—either there must have been formed a toxin, with the subsequent production during recovery of an antitoxin, in the blood serum, in which case the serum, filtered through porcelain, should have a therapeutic and preventive property if used as a vaccine for the pest; or the white corpuscles (phagocytes) have acquired the power of destroying the microbes of the disease, in which case the inoculation of unfiltered blood would probably prove to be an efficacious treatment. Your Excellency will observe that in this process it is not proposed to introduce into the beast to be protected any disease organism, as it is essential that the animal should have quite recovered from a sharp attack of the pest, so that whatever change, be it the production of an antitoxin or the stimulating of the white corpuscles, the microbe can produce in the blood of animals has been carried to its fullest extent."

6. Jan. 3rd, 1897.—Dr. Koch's Reports, p. 7: "And also the circumstance that in the bile of most of the cases examined I have found in pure cultivation a bacterium, which, according to the description published, is conformable with the microbe discovered by Dr. Simpson in Calcutta and declared to be the cause of rinderpest. All these experiments with bile, however, had negative results. We are consequently justified in saying that bile does not contain the contagion of rinderpest, and that Simpson's bacterium cannot be considered to be the microbe of rinderpest."

7. Jan. 31st, 1897.—Dr. Koch's Reports, p. 13: Experiments with serum of "salted" cattle described. "These experiments demonstrate that the serum of immune animals possesses a certain protective power."

8. Feb. 10th, 1897.—Dr. Koch's Reports, p. 15. Shows that the effect of the serum is only temporary. "A second and equally important fact is that one is able to render immune healthy cattle with the bile of such that have succumbed to rinderpest."

9. Feb. 13th, 1897.—Letter to *Cape Times* (not inserted): "What has occurred to the microbes that have been alleged to be the cause of rinderpest? Dr. Simpson's microbe was disposed of in a very summary fashion, but it will not surprise me if a good deal more is heard of this organism in the future."

10 Feb. 17th, 1897.—Letter to *Cape Times* from Mr. G. E. Cory, Grahamstown, Feb. 13th, enclosing letter from Dr. Simpson, Calcutta, Jan. 8th: "I have, however, two animals which have been rendered immune against the rinderpest microbe." (Compare with paragraphs 6 and 9.)

11. March 1st, 1897.—Letter to Secretary for Agriculture: "I am

Digitized by Google

anxiously waiting for Dr. Koch's further announcements, as there is a point he may possibly overlook, and if so there may be trouble in store."

Contradictory reports of the bile cure now began to appear in the press.

12. March 26th, 1897.—Letter to Secretary for Agriculture: "Let me ask you to compare the last paragraph of my letter of the 1st inst. with Dr. Hutcheon's letter which appeared about the 16th inst. and with the reports that keep coming to hand of the results of the bile method, and I think you will agree that I was well able to see the danger ahead, and it may be mentioned that there is even graver danger in a rash use of the serum method on the lines laid down in Dr. Koch's last report." This method will be found on p. 19, Dr. Koch's Reports.

13. April 22nd, 1897.—Letter to Mr. Theron, Chairman, Rinderpest Committee: "I should consider, however, that it is very probable indeed that in the virulent blood, at a certain stage of the disease which would have to be ascertained by experiment, there is a maximum amount of the poisonous toxin. Then, if the blood were taken at this stage and filtered through porcelain, keeping in an ice chest being insufficient, in order to remove all organisms, and this filtrate were mixed with the serum taken from salted cattle, I think a powerful vaccine would be obtained that might perhaps give an immunity of a more lasting character." "Probably it would be found, if the method indicated above were tried, that before a perfect immunity could be secured several inoculations would have to take place, but you will notice that *no* disease organism would be introduced into the beast to be protected, and this is, in my opinion, a condition of the greatest importance."

13*a*.—"As regards the bile process it will be found that in one of Dr. Koch's early reports he stated that he found a bacillus present in the bile in pure cultivation which he took to be Simpson's microbe, but as an injection of this gall did not impart the disease the conclusion was drawn that this microbe was not the cause of the disease. In another report he shows that the antitoxic property of a gall was so great that a mixture of equal parts bile and rinderpest blood did not communicate the disease. This experiment shows that, under certain conditions, bile is able to counteract the disease organisms, and if this be the case is it not possible that Dr. Koch has drawn too hasty an inference from the fact that his microbe-containing gall did not communicate the disease! If this surmise of mine be correct it would explain the very contradictory reports about this process; the extract in the *Argus* of the 20th inst. from the *Bechuanaland News* and the telegram from Dr. Hutcheon read yesterday lend strong support to my views, for if the gall were rich in microbes and weak in antitoxic material the disease would appear in the treated cattle; while if the reverse were the case immunisation without any sickness would result, and according to the relative proportion of these two ingredients the disease would either not appear at all or in a longer or shorter time." "Here, again, filtration through porcelain would probably eliminate this source of trouble, and the bile method might then be used with the certainty of not communicating the disease."

14. May 7th, 1897.—Select Committee's Report, Mr. Hutcheon's evidence:—987. "It is only now dawning upon us that we will be able to correct the failing in inoculation—namely, its tendency to communicate itself to a number of herds when one is inoculated. Another point that has become clear to us is that by the present inoculation you get a certain number of cattle in the herd infected; complete immunity is not given to others, but the disease slumbers on and we find afterwards that the immunity is not permanent. Hence we get the disease much prolonged beyond what it would have been if we had allowed it to go on in the herd." (Compare 13*a*.) 1003. "There is another point that we have not decided yet. There is bile and bile. We are only finding out now that there are a great many things with reference to bile that we did not know before. I am satisfied of this, that though the physical appearance of different samples of bile may be the same, there is a difference, because you may inoculate with the same bile in appearance and no bad results seem to follow. You do not communicate the disease, and so far as we have seen the herd remains healthy. In another case of two biles the same in physical appearance you have very unsatisfactory results, although every care is taken. The same parties would inoculate. I selected a great portion of the bile myself and others inoculated, so that there should be no contact between me and the cattle, and yet the results were different. Now Dr. Turner and Dr. Edington have made a statement that they can test this bile and determine what is satisfactory and what is not, and it is quite possible that they will. If they effect that, and it can be practically carried out, and according to their statement they can, for they will use the spectrum to see whether the bile be good or bad. Now these are points that have to be proved." (Compare 9, 13*a*.) 1011. "Dr. Koch recommended bile as the most reliable thing. Dr. Kohlstock and Dr. Turner are convinced that bile is the thing, notwithstanding the unsatisfactory results. And it is a curious thing that the herds they have inoculated have been satisfactory in results. No disease appeared in them after inoculation. We have some in the Herschel district, but the disease appeared after thirty days from infection from outside." (Compare 13*a*.) The main point in Mr. Hutcheon's evidence is the suggestion to inoculate first with bile and then ten or twelve days later with virulent blood.

15. May 10th, 1897.—Select Committee's Report. Dr. G. Turner's evidence:—1144. "My opinion is that inoculation with proper gall confers immunity on the cattle." 1145. "I cannot say permanent because the cattle longest inoculated only date back about three or four months. We have sent down to that farm to have the cattle inoculated with rinderpest blood to ascertain whether they are immune. Five of these cattle were inoculated on Friday last with virulent blood." 1146. "You can tell [the proper kind of gall] to a certain extent by the colour. The green gall is the best gall, but even amongst green gall there are choices. A gall which apparently resembles good gall may not confer immunity. I hope in a short time to be able to tell which is good and which bad gall." 1147. You have made experiments with the spectrum with reference to this, and you noticed certain lines in the galls which rendered cattle immune? "Yes." 1148. What are they? "I am sorry you ask me this, as I have not finished yet. I come forward thus with the greatest diffidence. In those galls that have acted well I have noticed the bands of the blood spectrum, not blood as we popularly talk of it, but blood colouring matter in the gall. Those were the galls that have answered. One or two galls that I have been doubtful about have failed to give these lines, and have merely presented the spectrum of ordinary gall." 1149. Do you still continue any other empirical attempts to find a remedy? "No; we have been trying to perfect the gall prevention method." 1150. You have confined yourself to that? "We are using the serum as well. We have immunised animals with serum, but apparently the immunising is not so powerful, and for that reason we have continued mostly on the gall line." 1151. You can immunise with serum? "Yes; Dr. Koch showed that by taking serum and putting 1 per cent. of rinderpest blood with it, and letting it stand for twenty-four hours, that 20 c.c. would immunise an animal, but it does not appear to give so powerful an immunity as the gall." 1152. Have you tried experiments with antitoxin? "Yes; we have not had time to separate antitoxin from serum. We used the serum from an immune animal. We know that the serum from an immune animal injected into the blood of another will protect it in a very few hours from rinderpest, but that immunity is not very powerful and passes off very rapidly. I took some of this serum and treated two oxen with a very large portion of this serum indeed, injected subcutaneously. One ox was given 50 c.c. in the morning and 50 c.c. in the evening, and the other 80 c.c. in the morning and 80 c.c. in the evening, and I believe this was done on three days before they died. I was very much disappointed, as I was in hopes that by using the serum it might be possible to save an animal. ..... I am, however, going to try it again." 1153. Do you notice microscopically the presence of phagocytes in the blood? "They are always in the blood." 1154. Then that would be antitoxin ones? "No; I have not been examining the serum in that way. As a matter of fact, the antitoxin is not an organised thing at all. It is a chemical substance. The effect of it when it enters the system is to enable the phagocytes to resist the attacks of the micro-organisms and destroy the bacilli. There are also chemical theories to explain the action of antitoxin." 1155. Then you simply give the phagocytes in the blood additional strength? "Yes." 1160. But you may inoculate even with bile that looks all right and produce the disease? "I wish to say that I have no experience of bile giving the animals disease. I have tried in every way to give animals the disease with the bile and have failed to do so. We have used all sorts of biles, but have not succeeded up to the present." 1161. "I have taken brown bile and inoculated an animal with it, and the animal was still alive after ten days." 1167. "The animals on the farm have taken 100 c.c. (rinderpest blood), while $\frac{1}{10}$ c.c. will kill a full-grown ox." (This evidently refers to 1145) 1176. "One of the best-known diseases is small-pox, and yet no one has isolated the organism of that disease. Although we know it is there, and cultivate it by introducing it into the cow and taking the vaccine from the cow; although we know it must be there, we cannot see it. So it is with the organism of rinderpest. I took 60 c.c. of bile in order to verify a theory of Dr. Koch's. I filtered it in a porcelain filter. I washed the filter with a salt solution that does not destroy the virus in order to wash away the liquid bile. I then examined it [what?—H. A. L.] under a microscope, but could see nothing. I then inoculated an animal with it [what? the residue or filtrate?—H. A. L.], but the animal received no ill-effect, and still the animal is immune. Something went into that animal which I could not see. I only know this from the results I arrived at, and could only see it with the eye of faith." 1179. You say that you do not know how long bile inoculation confers immunity? "No, I do not." 1180. Dr. Hutcheon stated here that he found after one month the immunity began to wear off, and the result was that the disease would remain in a herd for months. In one case fifty had been dying over a long period, and are not done yet. Dr. Hutcheon therefore recommended that all animals ten or twelve days after the bile inoculation should be inoculated with rinderpest blood. In that way he thought to drive the disease out of the country. Do you agree with that? "I think if the experiments being made prove that the gall alone is not sufficiently powerful, that is the right way to set about improving the methods." 1181. He says that unless you inoculate with rinderpest blood you may have the disease among the animals for a very long time and keep up centres of infection? "If you use a bile which does not happen to be good that which he describes might take place, but I cannot tell you that I know it of my own knowledge. The case in which this was tried was in a district which had rinderpest all round it. It is true that this bile came from Dr. Koch himself, but I am perfectly prepared to admit and am confident that all bile does not grant immunity." 1182. What is the special virtue of gall for the purposes of inoculation? "That is a question which I had a long discussion with Dr. Koch about. Dr. Koch's view is this: that the bile contains a chemical substance something like an antitoxin, and that it also contains the rinderpest organism unmitigated and in its full virulence. [Compare par. 13*a*.] He said that was so because it was well known that a ½ per cent. of carbolic acid would destroy the virus in blood in twenty-four hours in the ordinary temperature of the room. He took a good rinderpest bile and added 0·5 per cent. of carbolic acid, kept it for twenty-four hours, and inoculated an animal with it. The active agent in the bile was destroyed and the bile lost its power. Then he took ten other centimetres of the same carbolised gall and added 10 per cent. of rinderpest blood and injected it immediately, and the animal did not suffer from rinderpest but was rendered immune. [Compare with 1167, there must have been something present to modify this rinderpest blood, the dose being sufficient to communicate the disease to 500 head of cattle.—H.A.L.]. Thus he believes he put back into the bile the virulent element that he had destroyed with the carbolic acid.....I filtered 60 c.c. of bile through porcelain. Now if Dr. Koch's theory was correct the animal into which I introduced this filtered bile ought to have died; it did not, but it was immune. [Compare 1176 and par. 13*a*.] I took the filtered bile, injected it into the animal, and that animal had the rinderpest after I infected it, but it recovered. From my experiments I do not think that the organism is in the bile in the unmitigated form." 1184 "I differ on a slight point from Dr. Hutcheon there. We are perfectly agreed as to what ought to be done, but we differ as to whether gall can give rinderpest."

16.—With regard to the experiment described in 1151 it was scarcely likely to be successful for (1) the disease had nearly run its course; (2) the method of separating the serum introduced by Dr. Koch, keeping in an ice chest, would have killed the phagocytes in the immune blood. My letter of Nov. 10th said, "B. Blood might be drawn from an (immune) animal and at once injected into the veins of the beast to be protected. Should it happen that the white corpuscles (phagocytes) have acquired the power of destroying the organisms producing the disease during the progress and recovery from it, then it may be expected this treatment will be the more efficacious." In this case active phagocytes would be introduced and consequently would exert their full influence.

17. May 15th, 1897.—Dr. Edington's report: "In my former reports I showed that virus kept over seven days could not be used to infect healthy cattle. I did, however, find evidence that such inoculation gave rise to some slight degree of immunity, and it therefore seemed to me that this immunising power could only be exerted by, and obtain, in virtue of the toxin as present in the blood after the microbes themselves had been destroyed." (Compare pars 5 and 13.). "I have further shown that animals which have recovered either from this inoculation (i.e., rinderpest blood used on or about the fifth day after its withdrawal) or from spontaneous infection are not absolutely immune." "I would add with regard to the bile method that if selected bile is immediately mixed with 50 per cent. of pure neutral glycerine that it is safely kept from putrefactive change, and if kept over six days, as I have indicated in my annual report regarding blood and mucus, it is impossible then to produce virulent rinderpest on inoculation while the toxin is not destroyed." (Compare 13a.) "My earlier experiments showed that glycerine does not exert a destructive action on the contagion of rinderpest, and I have since found that it appreciably conserves its virulence, although not to any great extent." (How are the statements in the last two paragraphs to be reconciled?—H. A. L.)

18. May 17th, 1897.—Dr. Kohlstock's reports show that serum from immune animals protects for ten days. Also that under certain conditions a gall can be sterilised by heat, but does not say whether it retains its effective power. A mixture of blood and this bile rendered an animal immune. The result of the experiment mentioned in 1145 and 1167 is given. The animals were in good health, with normal temperatures, after the lapse of eight days. (Compare 17, par. 2). "Animals which were injected with brownish-green gall, containing the Simpson bacillus in pure culture, or gall of a brownish colour, containing both bacteria and streptococci, became immune without the occurrence of any accidents, such as abscesses, &c." "Thick, green gall, free from smell and organisms, has often been taken from dead cattle; on one occasion I rendered an animal immune with such a fluid."

"THE NON-POSSUMUS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Your leading article on this subject ought to meet with the warm approval of every Fellow and Member who desires to see the College something more than a mere examining board. The situation is not new. The council is only carrying out its traditional policy of refusing to act for the promotion of the interest of those who constitute the College; in my opinion it always will so refuse to act until it becomes really and not falsely representative of the majority of its constituents. The letter of a "Fellow of the College," in THE LANCET of July 17th, hits the mark; "there can be no true representation unless the representative is responsible to those he represents." The question is one of principle. The dominant party on the council maintains that the College is a purely scientific body, and has no concern with the affairs of its Fellows and Members, except in cases of gross misconduct. In the words of a recent president the Council will not "fight the puny battles of the Members." Unfortunately for this contention, it is bound by the by-laws to "protect and defend every Fellow and Member of the College who may be disturbed in the exercise and enjoyment of the rights, privileges, exemptions, and immunities acquired by him as a Fellow or Member thereof." This by-law is the Magna Charta of the Fellows and Members, and to it the Council will be held on any and every opportunity. The Council has already stultified itself in the case of Mr. Anderson by first recommending it to the notice of the profession as one of great hardship and then refusing to do anything to "protect and defend" him. We intend to give the Council many further opportunities of such stultification, until at last it recognises that if the Fellows and Members are bound to observe the by-laws, so also is the Council.

You justly say that the situation is serious, but if the Members are in earnest about asserting their rights the solution will not be much longer delayed. If all those who have been disturbed or injured in the exercise of their profession by medical aid associations, insurance companies, or in any other way, will communicate with me, I know that the committee of the Society of Members will coöperate with them in pressing their grievances on the notice of the Council. It is only because the great bulk of the Fellows and Members have *not* been in earnest that hitherto so little progress has been made.

I am, Sirs, yours faithfully,

W. G. DICKINSON,
Hon Sec., Society of Members of the Royal College of Surgeons of England.

West Hill, Putney, S.W., July 26th, 1897.

THE LATE MR. F. W. ELLISON: AN APPEAL.

To the Editors of THE LANCET.

SIRS,—I should be very greatly obliged if you would have the kindness to insert the enclosed letter from Mr. Hatfield. The case to which he refers is one into which I have myself very carefully inquired. I am quite sure it is perfectly genuine, and it appears to me to be one in which we may, with every hope of success, appeal for help to the readers of THE LANCET. Any subscriptions that may be sent will be gratefully received by Mr. Hatfield, York House, 1, Park-road, Forest-hill, S.E., or by myself, and will be at once acknowledged.—I am, Sirs, faithfully yours,

HOWARD MARSH.

30, Bruton-street, Berkeley-square, W., July 23rd, 1897.

[ENCLOSURE.]

DEAR MR. MARSH,—I want to bring before the profession the sad case of Mr. F. W. Ellison, a former student of St. Bartholomew's Hospital, who died last September at Glenely, Adelaide, after two days' illness, aged forty-two. He took the M.R.C.S. in 1878, and after practising for five years at Catford he went to Australia twelve years ago and managed after some time to make a living at Glenely. He has left a widow and six children totally without means. The eldest, a boy aged sixteen, has weak lungs; the youngest is a boy aged six. Mrs. Ellison and her family are now in this country, and are entirely dependent on relatives, who are by no means well off. Up to the present time they have received small remittances from Australia, the result of the collection of book debts, but these have now almost ceased. An aunt has undertaken the charge and support of one of the daughters, and we wish, if possible, to secure for the family a small house within reach of some good school. They have, however, no furniture, and the friends are anxious to raise a fund for the purpose of buying some for them. If you can help me in this I shall be very glad. I have before me some flattering testimonials to Ellison's good qualities from yourself, the late Dr. Black, Dr. Gee, Sir Dyce Duckworth, Dr. Clement Godson, and Mr. Walsham, so I expect he will be well remembered at the hospital. He was a charming man and a great friend of mine when he lived here.

I have already been helping in some way, and I propose to subscribe to any fund that may be opened, and my friend, H. A. Francis, who wrote from Vancouver immediately he heard of the death, has informed me that he also should subscribe.—Believe me, yours sincerely,

W. H. HATFIELD.

York House, 1, Park-road, Forest-hill, S.E., July 23rd, 1897.

"A METHOD OF UNITING THE DIVIDED INTESTINE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 22nd, which I received some days ago, I have read a note by Mr. G. Lenthal Cheatle on a Method of Uniting the Divided Intestine. It might be of interest to your readers to know that I have employed in two cases the same procedure with the best results. Owing to the difficulties caused by not having instruments other than scissors, knives, and common suture needles, it came to my mind to convert the intestine into practically a flat ribbon by a longitudinal incision to make sewing easy. Thus I had first the idea of uniting the divided intestine by the method mentioned and transformed it into a definite surgical procedure. In a work which I have taken in hand, which will soon be published, I shall describe the *modus faciendi* used in my two cases.

I am, Sirs, yours faithfully,

Dr. PACHECO MENDES,
Professor of Surgery, Faculdade de Medicina.

Bahia, Brazil, July 5th, 1897.

"CYCLING FOR WOMEN: ITS EFFECT ON PARTURITION."

To the Editors of THE LANCET.

SIRS,—Your correspondent, Mr. Haydn Brown, in his lengthy criticism of my letter evidently jumps to the conclusion that I condemn cycling for women; whereas I merely drew attention to the dangers of over-exertion and the use of unsuitable saddles.

With regard to the perineum being untorn, I only stated the fact and made no pretension to skill with the short forceps, which nowadays the veriest tyro in midwifery finds no difficulty in using. I do not think it likely, as Mr. Brown supposes, that my remarks are likely to deter any of the fair sex from enjoying the pastime of cycling, which when indulged in moderately is a healthy and graceful form of exercise. I am, Sirs, yours faithfully,

July 28th, 1897. J. MCVITIE, M.R.C.S. Eng.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

XII.—BIRMINGHAM.[1]

The Hospital Reform Inquiry.—Utter Collapse of a Promising Movement.—Disorganisation and Disunion.—The Rapid Growth of Grievances.

NOWHERE, perhaps, is the question of hospital abuse fraught with so many complications as at Birmingham; but, whatever may be the difficulty of the problem, by far the greatest obstacle to reform is the lack of union among the medical men themselves. The profession has been infected by the contagion of the surrounding commercialism. Only a small proportion of the inhabitants of Birmingham were born and bred in the town. People rush in from the outside in the eager hunt for money. They simply strive to "make their pile" and haste away again. Among such a population it is difficult to spread altruistic ideas; it is a wild endeavour all round after business each for himself, and but few pause to consider what are their duties to society. This spirit also animates, more or less—let us hope very much less—the medical profession, and therefore it has been more particularly difficult to group the medical men together and get them to put their personal interest in the background so as to defend the position of the profession as a whole. In smaller towns, where the spirit of commercialism is not so paramount, organisation has been more easily accomplished. In Birmingham it suffices for one set of men to attempt to form an organisation or to start a movement, and at once another set of men are stirred with suspicions, or even moved to open hostility. Instead of inquiring what good cause is to be promoted, they will strive to find out that some personal interest is to be served. In a town where most people are seeking to enrich themselves it is difficult to believe that anyone is only seeking the general good. Perhaps this may account for the fact that in Birmingham the members of the medical profession do not hold together and have failed to understand the force and beauty of the doctrine of solidarity. Yet there was, some years ago, a movement which should have given a powerful impetus to the medical profession. In 1889 several meetings were held by the medical men practising in Birmingham to discuss the question of hospital abuse. In October of that year a preliminary report had been drawn up by a committee of medical men elected at these meetings. It was proposed to submit this report to a large public meeting of all persons interested in the medical charities of the town.

This report set forth that the demands upon the medical charities were greater than could be met, because these charities had been diverted from their original purpose. A too large proportion of the public resorted to the hospitals to the detriment of the interest of the subscribers and of the medical men, while it lowered the dignity of the recipients. Therefore, hospital reform was needed, so as to encourage providence and supplement the action of the Poor-law. Hospitals were originally intended for the poor, and were supported by those who expected no benefits in return. The report then went on to say that "under the 'ticket system' it is notorious that tickets are often given to unfit persons; are purchased either directly or indirectly by those who propose to use them, and are thus diverted from their proper purpose. Under the so-called 'free system,' though inquiry is usually made as to the position of the applicant, the same abuse exists. Many persons who are well able to pay for the services of a competent medical attendant, and not a few who could afford the fee of a consultant or specialist, elude the inquiry and obtain gratuitous treatment. Among the in-patients are often to be found well-to-do persons who, requiring a surgical operation or having met with an accident, prefer to be treated in a well-ordered hospital rather than in their own homes, and disregard the fact that they have no right to accept either the benefits of a charitable institution or the services of a medical man without paying for them in full. In this matter the medical profession is not altogether free from blame. Hospital officers acquiesce in the admission of unsuitable cases; other medical men are not always sufficiently careful as to the status of those whom they recommend for hospital treatment."

The report goes on to say that the number of out-patients is often so great that the serious cases suffer considerably from having to wait a long time, and that sufficient attention cannot be given to each case. As regards the in-patients, persons requiring surgical operations are occasionally kept waiting weeks because there is no bed vacant, while the stay of those who are admitted is sometimes undesirably shortened so as to make room for those who are impatiently waiting their turn. "Furthermore, the over-pressure on the time and energy of the medical officers is apt to interfere with the due discharge of their duty as teachers. It has therefore been necessary to appeal for more funds so as to enlarge the hospitals; but though these appeals have met with a generous response the pressure still increases, because no attempt has been made to deal with the root of the evil—namely, the indiscriminate extension of charity." The Report then goes on to show that whereas the total number of cases treated by the medical charities of Birmingham amounted to 67,000 in 1867 they were equal to 166,000 in 1887. The population of Birmingham was 325,895 in 1867. In 1877 it had increased 15·81 per cent. and reached the figure of 377,436. In 1887 the population was estimated at 441,095, an increase of about 35 per cent. in the twenty years. But the ratio of patients treated by the medical charities as compared to the population was 1 in 5 in 1867, 1 in 3·5 in 1877, and 1 in 2·6 in 1887. This is an increase in the number of patients as compared to the population equal to 147 per cent., though the population only increased 35 per cent. Thus the number of hospital patients during these twenty years augmented more than four times as rapidly as the population of the town. These figures, however, must not be taken too literally. There are a good many patients in the Birmingham hospitals who come from out-lying districts and from other towns. Also the hospital returns are not correct in the sense that a patient may be entered twice over in the same year, and is reckoned as two patients, when the entry refers to one and the same individual. But these reservations apply equally well to the figures given for 1867 as to those for 1887. The proportion of the increase stands as stated, it is the proportion of patients as compared with the population which must be reduced. The report says, however, that there can be but little doubt that one-third, not of the sick, but of the whole population, receives gratuitous medical treatment during the course of twelve months from the hospitals.

The preliminary report of the committee also deals with the question of the Hospital Saturday Fund, but this phase of the problem is so important that it must be treated separately. The report concluded with the opinion that a large portion of the work done in the out-patients' department of the hospitals should be relegated to provident dispensaries, and that those who are too poor to join such institutions should come under the Poor-law. The voluntary hospitals should only deal with severe cases, and when necessary the provident dispensaries and the Poor-law infirmaries should be available for purposes of medical education. The report finally deprecated any idea of effecting suddenly radical changes, but urged the necessity of a fuller inquiry. This preliminary report of the committee was submitted to an influential meeting of the profession held on Nov. 20th, 1889. All medical men within a radius of twenty-five miles had been invited, and ninety medical men were present. The meeting unanimously voted "that the statements contained in the report are deserving of the serious attention of the public and the administrators of medical charities."

Further resolutions urged that an inquiry should be held, and that a committee should be elected to represent the profession, which should approach the mayor with a view to convoking a conference on the subject. This was done, and a numerously attended conference met in the council chamber on Jan. 15th, 1890. After a lengthy discussion it was resolved that the mayor should appoint a committee of

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; (9) May 8th, 1897, France, United Action and Legislative Action; (10) May 15th, 1897, Leicester; and (11) June 5th, 1897, Nottingham.

Digitized by Google

inquiry, and the mayor nominated Judge Chalmers as chairman of this committee of inquiry. The committee consisted of Mr. C. T. Saunders or Mr. J. C. Holder, for the General Hospital; the Rev. J. C. Blissard, for the Queen's Hospital; Mr. F. Keep or Mr. Alderman Lloyd, for the General Dispensary; Mr. Councillor Ball, for the Hospital Saturday Committee; Mr. R. H. Taunton, for the Children's, the Eye, and the Women's Hospitals; and Dr. A. Harvey, Dr. Rickards, and Mr. Priestley Smith, for the medical profession. Mr. W. S. Pritchett was secretary of the committee.

This committee held seventeen meetings, examined a number of witnesses, and finally issued a printed report. With regard to in-patients this report stated that though possibly there may have been isolated cases of abuse there need be no apprehension that money was wasted in this respect. The average cost of in-patients varied from £2 17*s.* in some hospitals to £4 10*s.* in others, while the average cost of each out-patient was only about one shilling. The committee agreed with the report of the previous committee as to the enormous increase in the proportion of persons receiving treatment at the hospitals, and stated that, "making allowance for certain sources of fallacy, they estimate from these figures that at the present time about one-third of the population of Birmingham, apart from the pauper class, receive gratuitous medical treatment in the course of twelve months." While these figures bore testimony to the high estimation in which the hospitals and their staffs are held by the public they proved that the medical staffs were overworked by the swarms of out-patients who crowd the hospitals. Therefore, complicated cases could not receive the prolonged investigation necessary and there was not time to give proper instruction to the students. The question of numbers did not, however, prove that rich people frequented the hospitals, and in dealing with abuse the committee seemed somewhat at a loss when it came to consider for what class of persons hospitals were really intended. The committee stated that "as long as the hospitals are independent institutions, free from any controlling authority, it is clear that each hospital has the power to determine for itself to what class of persons it shall open it doors." Still the feeling seemed to be that hospital patients should constitute a middle zone between paupers and the well-to-do classes. The destitute have greater advantages in resorting to the Poor-law than to the hospitals because they can then obtain food, clothing, fuel, &c., as well as medical treatment. Besides, at Birmingham out-door medical relief is admirably organised by the Poor-law guardians. There are medical stations in different parts of the town where patients can call or send for the medical officer to attend to them at their own homes. Medical treatment is always granted in the first instance, but if the patient is able to pay the guardians are empowered by law to recover the amount due. It should further be noted, and this is very important, that the receipt of out-door medical relief does not involve any civil disqualification. Under such circumstances nearly all the out-door patients of hospitals might be referred to the Poor-law, but the committee was of opinion that the receipt of Poor-law relief had a demoralising effect and that the wealthy classes do well to subscribe to hospitals so as to prevent this result. In the abstract it is difficult to see why the receipt of charity from a hospital should be less degrading than the receipt of charity out of the rates; but in practice a great difference does exist—at least, in the minds of the people. Indeed, this accounts in a measure for the readiness with which the working classes subscribe to the hospitals.

The report then proceeds to deal with the difficulty of establishing a wage limit, for so much depends on the incidence of the illness; and it adds that "wherever the line should be drawn between fit and unfit cases the great weight of the evidence shows that as regards out-patients it is widely transgressed in Birmingham." There was conclusive evidence that the hospitals are largely resorted to in trivial cases. According to Dr. Simon there were 4000 trivial out of 10,000 cases. "Mr. Jordan Lloyd stated that very many of the cases he attended at the Children's Hospital were cases of neglected dirt. Mr. Lawson Tait was of opinion that many patients came to the Hospital for Women 'to see old friends and make new ones.' When they came to be medically examined they described impossible symptoms, and he found that there was nothing the matter with them. Mr. Marsh, on the day he gave his evidence, had been consulted at the hospital for a spot on the arm which proved to be a flea-bite, for a small, superficial abscess, and by a woman who thought she must have a cancer because her husband was said to have it." The committee were of opinion that all cases that could be efficiently treated by any qualified practitioner and which required no special medical or surgical skill were unfit for the hospitals. Most of such cases could be met by the payment of the ordinary medical fee or by joining a provident society. The hospitals should not compete against such societies by opening their doors to all comers. But of course the public would prefer to obtain the advice of a hospital surgeon or physician of high reputation rather than that of the medical officers of clubs. It is for the hospitals to shut their doors against such cases.

As the work done by the visiting staff is unpaid, it might be urged that the pressure could be reduced by increasing the staff. Such increase would, however, lower the reputation of the hospital staffs, prevent the best men in the profession from competing for these appointments, and the committee urged that "such a result would be disastrous, for, in the first place, the poor would no longer be able to command the highest medical skill, and in the second place, the rising generation of students would no longer be taught by the best men."

The committee was of the opinion that it was the fault of the hospitals themselves if unfit cases were admitted, but that this could not be prevented unless all the hospitals combined to exclude such applicants. "Any partial reform would be likely to shift the unfit cases from one hospital, or group of hospitals, to another." It was suggested that patients should only be admitted if recommended by a qualified medical practitioner or by a provident association or dispensary the rules of which were approved by the hospitals. This would be a stimulant to the good provident societies and "the hospitals would resume their special function of giving second or consulting opinions to the deserving poor." To carry out these reforms the committee proposed that a general council should be formed at which the managers of the Saturday and Sunday Hospital Funds should send representatives. The general dispensary, the city corporation as responsible for the city hospital, the guardians as responsible for the workhouse infirmary and for out-door medical relief, should also send representatives; and these, together with the delegates of all the hospitals, would fully reflect the opinions of the public medical institutions. The report of the committee, however, proceeds in a great measure to stultify itself by insisting that this council "would be almost purely consultative. It would have no power of forcing its opinions on individual institutions, except in so far as it could bring public opinion to bear on them. It might or might not be advisable that some such council as suggested should have certain controlling powers over hospitals, but those powers could only be given by the Legislature. It is obviously beyond the province of the committee to go into any suggestion involving more than voluntary coöperation between the existing hospitals."

This last quotation is a good illustration of the utter want of backbone that characterised all the efforts made at Birmingham. To say that a general council, constituted as suggested above, would have no power is either false in fact or it means that it is not worth while bringing such a council into existence. It seems, on the contrary, that a representative body of this description, if it was determined and earnest in its purpose, could exercise strong coercive powers. If this general council agreed by a large majority that certain rules should be enforced, how could any individual hospital resist? First, the Saturday and Sunday Hospital Funds would cease to contribute to the recalcitrant hospital. Then the general council would lay the whole matter before the public and call upon the subscribers to cease their subscriptions. Finally, they might invite the honorary medical staff to withdraw from the institution in question and make it somewhat difficult for the staff to refuse. It seems that a general council could easily ruin any institution or hospital that refused to submit and agree to the common discipline, but, of course, the members of such a council must be determined, must mean business, and must be ready to fight with every weapon available, instead of being satisfied with mere flabby conversation. The report of the committee concluded with the five following recommendations:

"1. The formation of a General Council representative of all the public medical institutions of the city.

"2. The formation of an inquiry agency to investigate the circumstances of applicants for treatment at the hospitals.

Digitized by Google

"3. That apart from first aid, and urgent cases, regulations should be framed by the hospitals to exclude trivial cases and cases where the patients are in a position to pay for such treatment as they may require.

"4. That facilities should be given for cases so excluded being dealt with by dispensaries or provident associations.

"5. That any person recommended by an approved provident association, or by a qualified medical practitioner should, as a rule, be admitted to the out-patient departments of the hospitals without further formality."

Though these recommendations may be open to criticism, and might be enlarged, they constitute for all practical purposes a good working basis. A programme may be more or less good; that is a matter of secondary importance; the whole question rests on the activity shown in realising the programme. An imperfect programme applied is better than a perfect scheme which is merely set down on paper. The real point is not what the Committee and the medical profession said, but what they did. In this respect it is difficult, while keeping within the bounds of courtesy, to describe and qualify what followed the publication of the Report of the Hospital Reform Inquiry Committee. Never was a reform movement on this subject launched under better and more influential auspices, and yet never did a movement so utterly collapse. The report when published was universally approved and with equal unanimity universally neglected.

This extraordinary collapse is explained in various ways. It is urged that the local press never really took the matter up. A principal lay manager of the General Hospital was opposed to reforms. As this is the largest hospital, it is difficult for the other hospitals to move without the approval of the General Hospital, and it cannot be said that the committee of this hospital has shown any very particular deference to the opinions of its medical staff. The managers of hospitals are to a great extent recruited from among the successful merchant class. Outward and visible success is their aim, and so long as the hospital they patronise has the largest number of beds and of patients they think the end is attained. Hence a spirit of competition was introduced which blocked the attempt at reform. Though the medical staff of the General Hospital had largely contributed to bring about the inquiry, when that hospital was invited to join in forming the proposed general council it failed to send any reply. Month after month passed by, and it was only when the agitation had simmered down and lost all its impetus that the General Hospital at last sent an answer. The impression seems to be that it was the delay on the part of this, the most important medical charity in Birmingham, that killed the movement. It has been urged that the Ethical Section of the British Medical Association should have pursued the matter; but in answer it is stated that they are only a consultative body and cannot take the initiative in any question. If so, it is high time that some organisation should be constituted which can take the initiative. An influential committee is appointed, an exhaustive report is issued, the whole of the profession agrees with its conclusions, and yet seven years are allowed to elapse without anything whatever being done. It suffices that a few laymen, members of hospital committees, should disapprove or fail to understand the necessity of the proposed reforms, and the whole of the medical profession is scattered like chaff in all directions, loses what little cohesion it had acquired, and quiescently allows the grievances it had proved and denounced to go from bad to worse.

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Netherfield-road Hospital for Infectious Diseases.

THE formal opening of the extension of the City Hospital North, Netherfield-road, took place on the 22nd inst. in the presence of the Lord Mayor. This hospital up to the year 1886 was carried on as a charitable institution for the treatment of infectious diseases. By the passing of the Liverpool Improvement Act, 1886, the corporation had vested in them the control of the Netherland-road Hospital. Several additions and alterations were subsequently made, comprising the erection of a new administrative block, laundry, mortuary, and boundary walls; a complete system of drainage was also introduced, together with new roadways, at a total cost of £13,640. By these means provision was made for ninety-six beds. In the year 1895 further improvements were made at a cost of £1000. The present extension comprises two new pavilions, having two wards in each pavilion, with ten beds in each ward, making a total of forty beds; also an isolation block, containing four wards with ten beds, additional accommodation being thus provided for fifty patients; by means of this enlargement the total accommodation is brought up to 146 beds. The laundry buildings have also been extended and provided with new machinery and fittings; these are to be used exclusively for cleansing patients' clothing, the old appliances being reserved for the use of the staff. A new lodge has been erected containing discharging-rooms, waiting-rooms, &c. The administrative block has also been enlarged, giving additional bedrooms for ten nurses and eight servants, the total staff now consisting of one resident medical officer, matron, twenty-five nurses, five porters, and twenty-two servants, total fifty-four, as against thirty-two prior to the extension. A new approach of easier gradient has also been made. The total cost of this scheme, including the cost of property purchased, furnishing, electric lighting, drainage, and laundry machinery, amounted to £28,000, while the area of the recent extension is 5500 square yards, thus enlarging the area of the hospital to 15,140 square yards. Each patient has 144 feet of floor space, and there are 12 lineal feet between each bed. At present there are sixty-four patients in the hospital, and it is gratifying to know that there is not one case of small-pox in any of the city hospitals.

The New Professorship at University College, Liverpool.

The conversion of the lecturership on hygiene at University College, Liverpool, into a Professorship of Public Health, alluded to in THE LANCET of July 24th, follows on the scheme matured by the College authorities for developing within the College a school of sanitary science, a full description of which was given in a former number of THE LANCET. Dr. Hope, who has been promoted to the new professorship, was appointed Lecturer on Hygiene in the year 1886, and in the following year became examiner in Public Health at the Victoria University. By reason of becoming a member of the professorial staff Dr. Hope will in future have a seat in the Senate of the College.

Distribution of the Hospital Sunday and Saturday Funds.

The joint committee of the Hospital Sunday and Saturday Funds have distributed £11,400 among the various Liverpool charities, being an increase of £400 on the previous year. There was a falling off in the Hospital Sunday Fund, but, on the other hand, the Hospital Saturday Fund shows an increase of £500 as compared with last year. The amount received by the Hospital Sunday Fund was £6028 and by the Hospital Saturday Fund £5726.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Post-Graduate Classes in Edinburgh.

ARRANGEMENTS have been made at Surgeons' Hall for a series of courses in the following subjects, to commence simultaneously on or about Sept. 27th:—Anatomy (Medical and Surgical), Bacteriology, Central Nervous System (Anatomy and Pathology of), Dermatology, Diseases of the Chest, Children, Ear, Throat, and Nose, Demonstration of Modern Gastric Methods, Electricity in Medicine, Gynæcology, Infectious Diseases, Ophthalmology, Ophthalmoscopy, Pathology, Practical Sanitation, Surgery (Clinical, Practical, and Operative), and Minor Surgery in Children.

The Hospital Difficulty at Aboyne, Aberdeenshire.

Sir W. Cunliffe Brooks, Bart., of Glen Tana, Aboyne, having, as stated in THE LANCET of July 17th, offered to pay £1000 if the fever hospital at present being erected about half a mile east from the village of Aboyne were transferred to a more isolated site, the Deeside District Committee have re-considered the question. While agreeing to take all steps to defend their action in view of an appeal by ratepayers to the county council, the district committee remitted to a sub-committee powers to meet

Digitized by Google

with the objectors and to make an arrangement with them. The Marquis of Huntly, from whom the present site was acquired, suggested a new site about half a mile farther east, and Dr. Watt, county medical officer, and Mr. G. G. Jenkins, the architect, are to report as to its suitability.

Women Students of Medicine at Aberdeen.

The graduation list of the University of Aberdeen on this occasion shows that one woman student has passed the first professional, while three others have passed the first portion of the same examination.

July 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE Prince of Wales, on behalf of the Queen, recently received a deputation from the Royal College of Surgeons in Ireland, consisting of Mr. William Thomson, President; Mr. R. L. Swan, Vice-President; Sir Charles Cameron, Secretary of Council; Mr. A. H. Jacob, Mr. F. T. Heuston, and Mr. L. H. Ormsby, Members of the Council.

The Outbreak of Beri-beri at the Richmond Asylum, Dublin.

There have been 124 cases of beri-beri in the Richmond Asylum since the new outbreak—a fact the significance of which needs no comment.

The Royal Academy of Medicine in Ireland.

The deputation from the Royal Academy of Medicine in Ireland, which was recently received by H.R.H. the Prince of Wales at St. James's Palace, consisted of Dr. James Little, President; Mr. John B. Story, Secretary; Mr. William Thomson, Dr. George F. Duffey, Dr. John W. Moore, and Mr. F. T. Heuston.

Medical Superintendentships of Irish Lunatic Asylums.

The Moderator of the Irish Presbyterian Church (Rev. Professor Leitch, D.Lit.) interviewed Mr. Gerald Balfour (Chief Secretary for Ireland) on July 21st to urge the claims of Presbyterian medical men to a larger share in the medical superintendentships of lunatic asylums in Ireland. He pointed out that of twenty-three of these appointments seventeen were held by members of the Church of Ireland, while Presbyterians, though almost equal in numbers as a religious body, only held one. Mr. Balfour replied that he would give the matter his best attention, and expressed his surprise at the figures quoted, and said that Presbyterianism should disqualify no one while he was in office.

The Royal Victoria Hospital, Belfast.

At a meeting of the City Council of Belfast, held on July 22nd (the Lord Mayor presiding), a very large and influential deputation from the promoters of the Royal Victoria Hospital attended to apply for a portion of the grounds of the present lunatic asylum in Grosvenor-street as a site for the new hospital. The Sites' Committee of the hospital and the medical staff, after most careful consideration, have come to the conclusion that this is the best place, and the deputation asked the corporation to grant them ten acres, or to recommend the Board of Control of Asylums to agree to the introduction of a Parliamentary measure authorising the transfer of, say, five acres now, or as soon as possible, and an additional five acres when the same might become available. The deputation having retired, the Council passed a resolution recommending the Board of Control to agree to the allocation of six acres as a site, and, if feasible, an additional four if hereafter required, the Board of Control to promote the necessary measure. The proposed site is an elevated one with two frontages (one opposite the Dunville Park), and it will in every way be most suitable. The medical staff of the hospital were unanimous in recommending it.

Professorship of Zoology in the M'Gill University, Canada.

I have pleasure in announcing that Mr. Ernest W. McBride, M.A., B.Sc. (London University), Fellow of St. John's College, Cambridge, and Demonstrator of Animal Morphology in the Biological Laboratory of that university, has been appointed to the chair of Natural Science in the M'Gill University, Montreal, Canada. Mr. McBride, who is the son of a highly respected Belfast merchant (Mr. S. McBride), was a distinguished student of Queen's College, Belfast, where he held the Senior Scholarship in Natural History in session 1887–88. At Cambridge, in addition to a most brilliant academic career, Mr. McBride was President of the University Union, and he has done some most valuable original work contributed to the Royal Society. He is also a graduate of the London University.

July 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Normal Thromboses in the Placenta.

AT the Academy of Medicine M. Delore mentioned that he had frequently met with thromboses under the chorion in the placentæ of women who had shown no signs of illness. He had made some bacteriological researches and was able to state that all placentæ contain microbes and thromboses in varying quantities. The microbes in nearly all cases are found in the thrombi. He cited two illustrative cases, the first, that of a woman in good health, a primipara, who had a perfectly natural labour lasting three hours. The placenta was placed in an aseptic box and the chorionic face was found covered with thrombi, and out of eight cultivations made from these seven gave positive results, micrococci, diplococci, and streptococci being found. The puerperium was, however, absolutely free from any complications. In the second case the woman was ill during her pregnancy, and had previously suffered from endometritis. Only a few thrombi were found, but many microbes. There are then normally found in the placenta microbes both living and virulent, and the researches of Desaubry and Bordier have shown that in the dog, after the assimilation of fat, there is found in the lymphatic and venous systems an abundance of microbes. It is probable that the same result follows in the pregnant woman after a heavy meal. As it is necessary that these microbes should not enter the fœtus the decolourised thrombi would seem to be a means of resistance and of protection for the fœtus employed by the organism against them.

The Antitoxin Treatment of Tetanus.

M. Nocard has brought forward a somewhat encouraging communication on the Treatment of Tetanus by Antitoxin. Experiments alone can solve this question, and those of M. Nocard were carried out with a toxin prepared at the Pasteur Institute in the form of powder and so virulent that 6 mgs. are enough to produce a fatal tetanus in the horse. If the immunising powers of the two anti-tetanus serums prepared by Hoechst and by the Institute are compared it will be found that they are not quite identical. An intravenous injection of either has no power to arrest the progress of tetanus once declared. Fairly satisfactory results obtain if the injection is made twenty-four hours before the appearance of the first tetanic symptoms, but the dose must be considerable. If injected forty-eight hours previously to the appearance of the tetanic symptoms the serum is almost always effectual, but the dose must be large and injected straight into the veins. Finally, if the serum be injected within twelve hours after the toxin has been injected the animal resists to a wonderful degree. If these conditions are adhered to the serum treatment would seem very effectual.

Stealing Inoculated Rabbits.

Parisians have been greatly alarmed by learning through the daily press that a robbery had taken place at the Auber-villiers Hospital, which is specially devoted to contagious diseases. A quantity of rabbits inoculated for some researches of M. Roger have been stolen, and they had been inoculated with diphtheria, tetanus, typhus, cholera, &c. As it is probable that the thieves sold the rabbits to dealers, everyone who supped off rabbit that evening is consumed with a horrible fear of having caught some infection. Interviews have been published with Dr. Roux and other authorities, and instructions have been given to the octroi officials to stop the entry of such rabbits, their carcases being easily recognisable by having been shaved for the purpose of inoculation. In case they come in skinned, instructions have been given for a very prolonged cooking, which, according to

Digitized by Google

Dr. Roux, would render them harmless as regards infection. "Scientific" thefts have been frequent of late. Last week there were stolen from the laboratory of M. Gautier a Ruhmkorff coil, a cage of birds, and some thirty white rats.

A Pasteur Medallion.

In December, 1894, the Municipal Council decided to place upon the wall of the higher normal school in the Rue d'Ulm opposite the building which was for a long time the laboratory of Pasteur some commemorative tablet. It was to consist of a black marble plaque with a medallion of the illustrious *savant*, and its execution was entrusted to a pupil of Roty. Until lately the plaque alone had been fixed, but at the end of last week the medallion was added, without, however, any ceremony. It is of bronze on a gilded base, and surrounded by a crown of oak and laurel in rose-coloured marble. The features of the great man have been reproduced from the celebrated medal of Roty.

Professional Secrecy and Divorce.

The *Cour de Cassation* has just decided, on the opinion of M. Falcimaigne, that "if it is ever allowable for a medical man to make known by letter to the wife of a patient who has confided in him the cause or nature of his illness, the rules of professional secrecy forbid him to authorise the said woman to publish the said letters, and especially as evidence upon which to demand a separation or plea of divorce. Such evidence would not be admitted by the court, even if given in with the consent of the medical man who wrote the letters."

Medical Responsibility.

Dr. Lassalette, who was condemned on June 12th to two months' imprisonment and a fine of 500 francs for the death of a patient who had been operated upon by him for the removal of a fibroma by laparotomy, and in whom at the post-mortem examination a forgotten pair of forceps was found, entered an appeal, but the only result was that his imprisonment was increased to three months.

July 26th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Bacillus Icteroides.

FROM Montevideo a fact reaches me which may be taken as a measure of the enthusiasm aroused by the "bacillus icteroides" and its discoverer. Dr. Antonio Quesada, a resident at Paso de los Toros, presented himself the other day at the Hygienic Institute of that city and asked for an interview with its director, Dr. Sanarelli. On being admitted he stated the object of his visit to be neither more nor less than this—to subject himself, under Dr. Sanarelli's eye, to inoculation with the bacillus icteroides. Dr. Sanarelli, while fully appreciating his courage and devotion to medicine and humanity, admonished him as to the risks he would incur and tried to dissuade him from his purpose. But Dr. Quesada remaining resolute, nay, expressing his determination to undergo the ordeal at other hands rather than not undergo it at all, Dr. Sanarelli had finally to give way and accept his offer. The experiment accordingly is imminent. Dr. Quesada will be accommodated in a special ward and be placed under the surveillance of a commission composed of three Uruguayan physicians and three of foreign nationality. With the inoculation of the bacillus the clinical observations will begin. The commission will examine with scrupulous care the respiration, the blood in its constituents and circulation, the several excreta—every channel, in short, through which a pathognomonic sign characteristic of yellow fever may be looked for. The effect of the inoculation ought to be instantaneous. After two days—always assuming that no complications supervene—the self-constituted "subject" to yellow fever will enter on convalescence and—still excluding complications or unforeseen contingencies—ought to be well in a week. The public, professional and lay, are awaiting the result of the experiment with intense curiosity, as a practical test of the validity of Dr. Sanarelli's findings and conclusions. Dr. Quesada, I may add, is a man of robust constitution and in the prime of life—forty-two years of age. He has served as an army surgeon with the Spanish forces in Morocco, in the Philippine Islands, and in Cuba, where he availed himself of his many opportunities of studying yellow fever. He has suffered from dysentery, and various febrile disorders, including malaria, but never, I believe, from yellow fever proper. He is, moreover, a professional man of exceptionally refined culture and, according to one who knows him well, "nutre molta fiducia nella scoperta di Sanarelli" (cherishes great confidence in the discovery of Sanarelli).

The National Medical Congress.

The "Congresso Medico Nazionale" will shortly be held at Bergamo, the picturesque, historical town on the Italian slopes of the Alps, and those of the profession from the English-speaking world who are taking their holiday in these regions might do worse than look in during its proceedings. Dr. Antonini, Superintendent of the Bergamasque Lunatic Asylum, acts as secretary to the Congress and, through his courtesy, I can anticipate the agenda-paper, so far at least as to specify the following themes to be introduced and discussed during the sittings: "The Application of Tuberculin for the Prophylaxis of Tuberculosis in the Lower Animals and in Man"; "The Question of Tuberculous Animal Food in its bearings on the Public Health"; "The Profession in its Relations to the Prophylaxis and Treatment of Tuberculosis"; "The Medical Attitude towards Consanguineous Marriages." This last is a very elaborate paper to be introduced by a special report from the pen of Dr. Roberto Massalongo, Professor of Special Pathology in the University of Padua. Among the other contributions I may signalise "The Necessity of a Federation among the Italian Medical Associations," leading up, I presume, to a discussion on the Santini Bill now before Parliament to put Italy in line with Switzerland and France in excluding from practice all English-speaking practitioners unprovided with an Italian diploma. From all I can gather our Italian *confrères* are by no means unanimous as to the wisdom or even economic advantage of legislation in Dr. Santini's sense. The "Prophylaxis of Pellagra" is another paper sure to contain much that is interesting, if only for the names of its "Relatori" (Dr. Marzachi and Dr. Antonini). "Hygienic Surveillance in Rural Communes" will be dealt with by Dr. Prati, while "The Organisation of Obstetric Assistance in Town and Country" will be introduced by a past-master of the subject, Professor Landucci, of the Padua school. Italian medicine will be powerfully represented at the Congress, which, taking into account the preparations on foot for its participants, native and foreign, will open with every prospect of brilliant success.

Dr. Maurizio Sacchi.

Just before closing the desk I receive an announcement which throws very grave doubt on the reported safety of the surgeon of the ill-starred Bottego expedition. "Contrary to the affirmations contained in the letter of Ras Maconnen," writes my informant, "according to which Dr. Maurizio Sacchi was in perfect health at Shoa, his family have received from the Consulta (the Italian Foreign Office) an intimation to the effect that the doctor, who had been intrusted by Captain Bottego with a caravan conveying a large quantity of ivory and whose escort consisted of but a few Ascari, had been attacked and robbed near Lake Rodolfo, and, while defending himself, savagely murdered. Evidently," adds the correspondent, "Dr. Sacchi was making for some seaport of the Benadir to discharge the commission confided to him by Captain Bottego."

July 25th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Census of Population.

FIFTEEN years ago an inaccurate and incomplete census was taken of Egyptian towns by the Government. The time was ill-chosen, for the urban population was engaged in revolt against the Khedive, many Europeans and others had fled the country, and those who remained were too frightened of the Arabi Pasha *régime* to answer questions truly. The consequence was that the numbers published were considerably below reality, and as no attempt has been made since then to correct them the birth-rate and death-rate calculated on the 1882 census have been notably absurd. This year the Egyptian Government succeeded in getting £30,000 from the Caisse de la Dette Publique for the expenses of a new census, and after a preliminary trial the numbering of the people took place on June 1st, which happened to

Digitized by Google

correspond with the first day of the Mussulman year. Everyone expected a considerable increase, but it looks, from the figures already published, as if the population of Egypt will have in future to be reckoned as nearer nine than six millions, and, if so, this will bring down the average death-rate from about 45 to 30 per 1000. The totals of 41 towns give an increase of 490,979 people, including the following additions:—Cairo, 201,562; Alexandria, 88,371; Port Said, 18,748; and Tantah, 23,538.

Control of Prostitutes.

Regulations have lately been made by the Ministry of the Interior for all houses where two or more habitual prostitutes live. Permission must be applied for in writing by the owner of the house, and licences are only issued to those quarters of the town chosen by the Governor or Mudir. Minors and ex-prisoners are disqualified, and a list of all residents and servants must be furnished. All women under the age of fifty years must be medically examined once a week, and those found to be ill are sent to the Government hospital. Inmates are not allowed to solicit publicly, and are not even to stand at their doors or windows. There is to be no gambling, police may inspect by day, and punishment for breach of rules is by fines of ten or twenty shillings, or by imprisonment from three to seven days. Thus it will be seen that Egypt is following the example of Malta rather than that of India, China, England, and the Straits Settlements. However, in Egypt there has been a certain amount of compulsory examination of native women since 1882. It is to be hoped that India will soon follow suit. This year's returns from Simla state that one-seventh of the whole British garrison may now be taken as ineffective in case of war.

Heluan-les-Bains.

Heluan has been for years considered as a future sanitarium, and it now looks as if its opportunity had really come. Last year a Government concession for the baths and two hotels was given to a rich company which already owns about £100,000 worth of property in Heluan and the railway connecting it with Cairo. The company decided to try to attract English visitors, and were fortunate in their choice of a resident physician. An entirely new bath establishment is to be built at once, and in the meantime there are fifteen baths for both sexes, two needle baths, and inhalation of sulphur spray vapour for bronchitis, as at Marlioz. A European masseur and masseuse are ready for the treatment of rheumatic and lung patients. The air of the desert—only sixteen miles from the luxuries of Cairo—is of unrivalled purity and dryness, for the Nile is two and a half miles away from the hotels, and the nearest cultivated ground is two miles distant. One hotel provides accommodation for 120 visitors, others for smaller numbers, and there are rapidly springing up a few boarding-houses and private houses for invalids. Altogether, about 250 people can now be comfortably housed. For amusements in this desert retreat the following have been provided: croquet, bowls, quoits, golf, practice cricket, and lawn tennis. Sand carts with ponies, riding horses, camels, donkeys, bicycles, a steam launch and sailing boats can all be hired. The nucleus of a good library also exists, and there are a swimming bath and a dark room for photography, and the management provides occasional concerts and an English military band once a week. A new era has dawned for Heluan, and an additional attraction is provided for invalids coming to Egypt.

Water Filtration by Native Filters.

Experiments show that the Egyptian filter jars of Nile mud which are universally used by Europeans and by some natives of the better class are useless when they are quite new, or much more than a year old. They are never very trustworthy, but they are apparently at their best when they have been used for eight, nine, or ten months. This is due to the inside coating of slime, which acts as the best filtering medium, as was pointed out by Professor Koch at Hamburg. When the filters (*ziehs*) are new they allow thousands of micro-organisms per cubic centimetre to pass through. A filter eighteen months in use allowed 1535 to pass, though the unfiltered water only contained 5000 micro-organisms per cubic centimetre; while several other filters in use a shorter time only permitted 400 to pass through from the same unclean water. The experiments are sufficient to prove that the *zieh* can be trusted to remove mud, but not microbes.

Cairo, July 24th.

Obituary.

WILLIAM HENRY ROBERTSON, M.D. EDIN., F.R.C.P. LOND., J.P.

DR. W. H. ROBERTSON had resided in Buxton for so many years, and had figured so prominently in both the public and the social life of the town, that his death, which occurred on July 15th, after a short illness, is being felt as a serious loss by all classes of the inhabitants. He was born in September, 1810, and studied medicine in Edinburgh, of which city he was a native, taking the degree of M.D. at the university there in 1830, after which he practised for a short time in Chesterfield. Removing to Buxton about 1834, he took a house in the square and had a dispensary in Terrace-road, on which foundation he built up a practice that was not only exceptional in its duration as measured by lapse of years, but brought him a gratifying amount of solid professional reputation, and gave him opportunities in many ways of displaying his excellent administrative talents. At an early period in his career he studied the effect of the Buxton mineral water in the treatment of disease, and the subject was one which never lost interest for him, for as the result of mature experience he held that in properly selected cases of a rheumatic or gouty nature these waters were truly valuable. On this account he had a special regard for the original Buxton Bath Charity, of which he was at the time of his death the only surviving medical trustee, and was chairman of the trustees and board of management of the Devonshire Hospital and Buxton Bath Charity since January, 1866, in addition to which administrative position he had been an honorary medical officer of the institution for sixty years, and senior consulting physician since 1865. Dr. Robertson was also chairman of the Buxton Improvements Company (Limited) from its commencement in the year 1870, and after the company was in the year 1888 reconstituted as the Buxton Gardens Company (Limited) he continued to be annually re-elected its chairman. He was the oldest member of the Buxton bench of magistrates, having been appointed J.P. for Derbyshire in July, 1867. Dr. Robertson became a Fellow of the Royal College of Physicians of London in 1872. He was the author of several treatises, relating chiefly to the Buxton mineral water, and he also contributed some articles on the same subject to the columns of THE LANCET; his "Guide to the Use of the Buxton Waters" has reached a twenty-fourth edition. Dr. Robertson has left a widow, a daughter, and a son, the Rev. Gordon Robertson, M.A., who is vicar of Sutton-on-Trent, Newark. The funeral took place at Christ Church, Burbage, on July 19th. There was a very large attendance, and out of respect to the memory of the deceased all the places of business in the town were closed whilst it was in progress.

PROFESSOR PREYER.

THE death has been announced of Professor T. W. P. Preyer, of Jena. He was born at Moss Side, Manchester, in 1841, and after a preliminary education in London and Bonn, studied medicine at Bonn, Berlin, Vienna, Heidelberg, and Paris. He graduated at Bonn, and in 1867 was appointed Professor of Physiology at Jena. His work on "Blood Crystals" (1871) is well known, as also his study of mental development entitled "The Soul of the Child" (1882). He also wrote on the "Colour and Temperature Sense" (1881), and in 1883 published a work entitled "Elements of General Physiology."

WATKIN WILLIAM ROBERTS, F.R.C.S. ENG., &c.

MR. ROBERTS, who died at Carnarvon on July 24th, in his seventy-eighth year, after an illness of several weeks' duration, was an old and much respected inhabitant of the town, and had an extensive practice in the counties of Carnarvon and Anglesey. He was born at Garnedd, in West Anglesey, and received his first medical training from his uncle, Mr. William Roberts, who practised in Carnarvon. In 1840 he obtained the qualifications of M.R.C.S. Eng., and L.S.A.,

Digitized by Google

after which he held several dispensary appointments in Ireland; but more than forty years ago he returned to Carnarvon and made it his home. In 1856 Mr. Roberts became a Fellow of the Royal College of Surgeons of England; he was also a Justice of Peace for Carnarvon, and for many years had a seat on the town council, at first as a councillor and afterwards as an alderman. Mr. Roberts was a widower; he has left a son and six daughters.

FRANK CHANCE, M.B. CANTAB, F.R.C.P. LOND.

DR. CHANCE, of Burleigh House, Sydenham-hill, who died at Nice this month, was a scholar, and especially a linguist, of unusual attainments. He was born in Birmingham in 1826, and studied medicine at St. Bartholomew's Hospital and Cambridge University, graduating there as B.A. in 1854 and M.B. in 1855. His aptitude for the study of languages was already so well marked that while at Cambridge he gained the Tyrwhitt Hebrew scholarship, and subsequently edited "Bernard's Commentary on the Book of Job," which was published in 1864. He was also for many years a member of the Old Testament Revision Committee. Dr. Chance became a member of the Royal College of Physicians of London in 1859 and a Fellow in 1863, but he can scarcely be said to have engaged in practice to more than a nominal extent. In 1860 he published a translation of Virchow's "Cellular Pathology." Dr. Chance was a widower, and has left one daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Hermann Wasserfuhr, an eminent hygienist of Berlin, at the age of seventy-four years. During the Franco-German War he organised the transport service for taking the wounded back, and he was afterwards employed in the arrangement of the medical department in Alsace and Lorraine. He wrote a good deal on military medical organisation, on malaria in Alsace, and on school hygiene, and was one of the founders of the *Vierteljahrsschrift für öffentliche Gesundheitspflege*.—Dr. Vigneron, Lecturer on Genito-Urinary Diseases in the Marseilles Medical School.—Dr. Delaissement, Surgeon to the Hotel Dieu, St. Quentin.—Dr. Don José Estéban Lorenzo, Clinical Professor of Surgery in the University of Salamanca.—Dr. Carlo Grillenzoni, formerly Professor of Anatomy in the Ferrara School of Medicine.—Dr. Dewindt, President of the Belgian Medical Federation.

THE BRITISH MEDICAL ASSOCIATION.

THE sixty-fifth annual meeting of the British Medical Association is to be held, as many of our readers know, in Montreal, but the general meeting for the transaction of business and consideration of Reports of Council and Committees and an extraordinary general meeting were held on Tuesday last at Exeter Hall, the latter meeting having been summoned in pursuance of the requisition of 100 members. Dr. H. BARNES, the President, occupied the chair.

The special business commenced with a motion by Mr. ARTHUR MAUDE in the following words:—

"That whereas long delay has taken place in giving effect to, and carrying into execution, certain resolutions of general meetings of this Association relating to the taking up of medical defence by the Association, and uncertainty is thereby imported whether such resolutions are binding upon the Association and the Council, and it is desirable that such uncertainty be removed, the following amendment of the twenty-fifth Article of Association be adopted as a special resolution; that is to say, that at the end of the twenty-fifth Article the following words be added—namely: 'And it shall be the duty of the Council to give effect to, or carry out as speedily as possible, all resolutions of general meeting, unless otherwise duly provided.'"

Mr. MAUDE, in speaking to his motion, said that he wished to clear the air of the doubt which existed in the minds of members as to the power of the Council and as to their own powers over the Council. He reminded the meeting that though the branches elected the Council (or rather some members of it) it made no difference in the responsibilities of the Council to the general meeting. The directors of a company were by law responsible to their shareholders in general meeting, however those directors might have been appointed.

Surgeon-Major POOLE seconded the motion.

Surgeon-Major INCE moved as an amendment:—

"That as the report of a strong committee on the subject of the reform of the constitution of the Association is about to be submitted to the members generally by the Council, any discussion upon a motion affecting the duties of the Council is for the present at least both premature and inexpedient."

Dr. BRASSEY BRIERLEY, Mr. LAWSON TAIT, and others continued the discussion. On the amendment being put to the meeting it was carried by 62 to 41. On the amendment being put as a substantive motion 71 voted for the motion, while 55 voted against it.

Dr. HUGH WOODS then brought forward the following motion:—

"That the Council of the British Medical Association be and is now hereby instructed to forthwith take all necessary steps to complete and legalise the special resolution adopted by the extraordinary general meeting held at Birmingham on the 13th day of July, 1896, and confirmed by that held at Carlisle on the 28th day of July, 1896, which resolution amplifies the Memorandum of Association, and provides explicitly for the application of the funds of the Association to the purposes of medical defence; and that until a detailed 'scheme' of medical defence shall be agreed to, the Council shall act in any case or matter of medical defence upon the instruction of a general meeting of the Association."

The concluding part of this motion was ruled out of order by the Chairman, and Dr. WOODS, in speaking to the remainder, accused the Council of having adopted the methods of the "heathen Chinee," dark and not straight. He also was understood to accuse the Council of having submitted the question of medical defence to the branches because they thought the branches would give a hostile vote, at which there were loud cries of "Withdraw," many members feeling that their good faith had been impugned.—The CHAIRMAN asked what was to be withdrawn, and Dr. Woods withdrew.—Mr. JACKSON, of Plymouth, having seconded the motion, a discussion followed, as a result of which Dr. WOODS withdrew his motion and an amendment was proposed by Dr. WELSFORD to the effect that the Council be instructed to take the necessary steps to confirm the alteration of the Memorandum of Association put forward at Birmingham in 1896. The amendment was carried by 65 to 64 votes. The figures being so close, a division was demanded, which resulted in 90 ayes against 89 noes.

Dr. RENTOUL withdrew a motion which he had on the agenda paper, and the meeting was about to adjourn when the result of the last division was called in question.

At two o'clock the meeting again assembled, when the Chairman stated that the first voting having resulted on a show of hands in 65 in favour of the amendment and 64 against it, there had been a division. On a division there were 89 in favour and 88 against. Under misconception as to what his powers were with regard to the giving of a vote he gave his vote against the resolution, so making the votes equal. "According to the Chairman's Handbook," he continued, "I ought not to have seen what the tendency was when I gave a vote. It will therefore be necessary to declare that the resolution was carried by a majority of one vote." This statement was loudly cheered.

The business of the extraordinary meeting being now concluded, Dr. Roddick, of Montreal, the President-elect, should have taken the chair at the general meeting, but in his absence Dr. H. Barnes, the retiring President, relinquished his seat to Dr. Saundby, the President of the Council. The usual congratulations and votes of thanks having been duly tendered, Mr. Wheelhouse and Sir Walter Foster were presented with the gold medals of merit, Dr. Saundby hanging them round the necks of these gentlemen. Dr. G. Sims Woodhead received the Stewart Prize, and Dr. Alexander Hill Griffith the Middlemore Prize. The building was then cleared of reporters while certain proceedings with regard to the proposed expulsion of two members from the Association took place, after which the members discussed the report of the Council and the reports of the various committees.

Dr. MYRTLE proposed:—

"That this meeting requests the Council to take definite steps to ascertain the opinion of members of the Association in the United Kingdom on the question of medical defence by means of an individual canvass by reply-paid letter or card."

This resolution was carried by 48 to 25. Subsequently it was decided to send this card to Colonial members also.

The balance-sheet coming before the meeting, Mr. LAWSON TAIT demanded to know where the costs in the case of Kingsbury *v.* Hart were to be found. After some anxious searching on the part of the Council the treasurer found them among the Association expenses, but this did not

Digitized by Google

satisfy Mr. Tait, who thought, first, that they ought not to have been paid by the Association at all, and secondly, that they should have been put down in the balance-sheet as a separate item. He, therefore, moved that the vote be reduced by the amount of the costs. Mr. Tait eventually withdrew his motion, not, however, before having said that "the gentleman who had been appointed to supervise the medical ethics of this case knew as much about medical ethics as did probably the Lord Chancellor."

The report of the Parliamentary Bills Committee drew forth some strong remarks about the Obstetric Nurses Bill, after which the meeting adjourned until Wednesday at 12 o'clock. After some formal business had been gone through, a lively discussion seemed probable on a motion by Mr. NELSON HARDY which was directed towards securing a vote to unattached members of the Association, but the motion was withdrawn on the understanding that the matter would come up for consideration later. Promise of some excitement, however, was given by Mr. LAWSON TAIT'S motion:—

"That 'inasmuch as it is specifically ordained in the ninth Article of the Association that the *British Medical Journal* shall be conducted by a paid editor, who shall be responsible for all that appears in its pages, except such matters as may be printed by direction of the Council. The *Journal* shall contain papers on medical science, and shall be considered the medium of communication between members of the Association'; it is desirable that the Council should exercise a more complete control over this paid editor, should secure the exclusion of such matter from the columns of the *Journal* as does not come within the strict limitation made in the said Article, and such matter as tends to defeat the legitimate objects of the *Journal*; and, further, should secure that the said editor is responsible under the terms of the ninth Article of the Association."

He complained that articles which were of paramount interest to the profession were often crowded out of the *Journal*. According to the Articles of Association the *Journal* should be conducted by a paid editor, who should be responsible for all that appeared in the *Journal* except such matters as might be ruled by the Council. The Reference Committee which was appointed by the Council was, therefore, totally illegal and improper. Mr. Tait then went on to ask how the mass of money for the payment of articles was distributed. The motion was afterwards withdrawn and the meeting adjourned.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In July the following candidates passed in the subjects indicated:—

Surgery.—J. S. Barnes, St. Thomas's Hospital; A. R. Bates, Edinburgh; T. Jones, Middlesex Hospital; F. T. Knott, London Hospital; C. H. Maskew, Birmingham; A. R. O'Fflahertie, and J. F. Porter, London Hospital; B. C. Stevens, St. Thomas's Hospital and Durham; and F. H. Wilkinson, Liverpool.

Medicine.—A. R. Bates, Edinburgh; A. W. H. Edgelow, Charing-cross Hospital; R. S. Elvins, Birmingham; W. R. Kemp, Cambridge and St. Mary's Hospital; A. R. O'Fflahertie, and J. F. Porter, London Hospital; P. D. Pywell, St. Thomas's Hospital; W. F. Reckitt, Guy's Hospital; J. M. Ritchie, Birmingham and Durham; and B. C. Stevens, St. Thomas's Hospital and Durham.

Forensic Medicine.—F. W. Chesnaye, St. George's Hospital; A. R. Bates, Edinburgh; R. S. Elvins, Birmingham; W. R. Kemp, Cambridge and St. Mary's Hospital; J. F. Porter, London Hospital; P. D. Pywell, St. Thomas's Hospital; B. C. Stevens, St. Thomas's Hospital and Durham; and S. A. Stride, London Hospital.

Midwifery.—A. W. H. Edgelow and J. M. Edwards, Charing-cross Hospital; R. S. Elvins, Birmingham; W. R. Flint, St. Mary's Hospital; G. C. Hobbs, St. Bartholomew's Hospital; W. R. Kemp, Cambridge and St. Mary's Hospital; J. F. Porter, London Hospital; P. D. Pywell, St. Thomas's Hospital; B. C. Stevens, St. Thomas's Hospital and Durham; and J. M. Wood, Middlesex Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise Medicine, Surgery, and Midwifery:—Messrs. A. R. Bates, T. Jones, W. R. Kemp, F. T. Knott, A. R. O'Fflahertie, J. F. Porter, W. F. Reckitt, B. C. Stevens, S. A. Stride, and F. H. Wilkinson.

UNIVERSITY OF ABERDEEN.—The following candidates have graduated as follows:—

Degree of Bachelor of Science (B.Sc.).—*Harold George Wickham Adan, Aberdeen; †Alexander Findlay, Aberdeen; and ‡William Coul McLaren, Dinnet.

Degree of M.D.—Charles Spencer Anderson, M.B., C.M., Swansea; Andrew Baxter, M.B., C.M., Darwen; Charles Harold Dyer, M.B., C.M., Cleckheaton, Yorks (under the new ordinances); Edward Meredith Griffiths, M.B., C.M., Abercarne, Newport, Mon.; James McRae, M.A., M.B., C.M., Huntly; Edmund Thomas Martin, M.B., C.M., Leeds; William Moir, M.B., C.M., Darwen (under the new ordinances); Duncan Neil, M.B., C.M., Acton; Williamson Rust Reith, M.A., M.B., C.M., Erdington, Birmingham; and James Ritchie, M.B., C.M., Liverpool.

Degrees of M.B. and C.M. (Old Ordinances).—John Veitch Baston, M.A., Inverness; William Hunter, Aberdeen; William Anderson Kinloch, Garmouth, Morayshire; Andrew Ross Laing, West Cults, Aberdeen; Herbert Frank Mitchell, Norwich; and John Alex. Rose, M.A., Cultercullen, Aberdeenshire.

Degrees of M.B. and Ch.B. (New Ordinances).—William Ainslie, Taltswell, Mintlaw, Aberdeenshire; William Howard Clark, Beccles, Suffolk; John Duff, New Noth, Gartly, Aberdeenshire; Henry William Garden, Lumsden, Aberdeenshire; William Scott Hall, Aberdeen; Alfred William Hare, Orleigh Mount, Lansdown, Bath; Andrew Alex. Robb, Aberdeen; John Roger, M.A., Kinbroon, Rothienorman, Aberdeenshire; Norman James Sinclair, Old Aberdeen; and George Albert Turner, Aberdeen.

William D. M. Donald, Banff, has passed the examinations for M.B. and Ch.B., but will not graduate until he has attained the necessary age.

Graduation Honours.—William Hunter graduates with Honourable Distinction.—John Murray Medal and Scholarship (awarded to the most distinguished graduate (M.B.) of 1897): Maurice George Robertson, M.A., M.B., C.M., Huntly. *Proxime accessit* Thomas W. Lumsden, M.B., Ch.B., Midmar. George Thompson Fellowship: William Hunter.

* With special distinction in Chemistry.
† With special distinction in Chemistry and Physiology.
‡ With honourable distinction. Old regulations.

The diploma in Public Health has been conferred on the following candidates:—

David Buchan, M.B., C.M. Aberd., Aberdeen; George Chalmers, M.B., C.M. Aberd., Huntly; William Ronaldson Clark, M.A., M.B., C.M. Aberd., Surgeon-Captain I.M.S., Bengal; George Melli, Duncan, M.B., C.M. Aberd., London; John Arthur Rinder Glennie, M.B., C.M. Aberd., Aberdeen; Thomas Harper, M.B., C.M. Aberd., Insch; Leonard Guscotte Haydon, M.B., C.M. Aberd., Exeter; Johnston Shearer, M.A., M.B., C.M. Aberd., Surgeon-Major I.M.S., Bengal; and James Samuel Hourston Walker, M.B., C.M. Edin., Nairn.

FOREIGN UNIVERSITY INTELLIGENCE.—*Erlangen:* Dr. Adolf Gessner has qualified as *privat-docent* of Gynæcology. He has been assistant medical officer in the University Gynæcological Clinic, Berlin. Dr. Kryger, assistant in the Surgical Clinic, has been recognised as *privat-docent* in Surgery.—*Heidelberg:* Dr. Georg Marwedel, first assistant in the Surgical Clinic, has qualified as *privat-docent* in Surgery.—*Iurieff (Dorpat):* Dr. Kessler, Extraordinary Professor of Gynæcology, has resigned.—*Munich:* Dr. Alfred Schönwerth has been recognised as *privat-docent* in Surgery.—*Tübingen:* Professor Döderlein, of Gröningen, where he has only been for about three months, has been induced to move to Tübingen as Professor of Gynæcology.—*Vienna:* Dr. Lode has qualified as *privat-docent* of Hygiene.—*Würzburg:* Dr. A. J. Rosenberger has been appointed Extraordinary Professor of Forensic Medicine.

THE DIAMOND JUBILEE AND THE MEDICAL CORPORATIONS.—A Court was held at St. James's Palace on July 21st, when H.R.H. the Prince of Wales, on behalf of the Queen, received addresses from a number of public bodies, including the following medical corporations and associations consisting either wholly or in part of medical men, the names of the members of the respective deputations being given within parentheses:—The Royal College of Physicians of Ireland (Dr. G. F. Duffey, President, Dr. James Craig, Dr. J. W. Moore, Dr. James Little, and Dr. T. W. Grimshaw); the Royal College of Surgeons in Ireland (Mr. William Thomson, President, Mr. R. L. Swan, Mr. A. Jacob, Mr. Francis Heuston, and Mr. Lambert Ormsby); the Royal Academy of Medicine in Ireland (Dr. James Little, President, Mr. J. B. Story, Mr. Francis Heuston, Dr. G. F. Duffey, Mr. William Thomson, and Dr. J. W. Moore); the British Institute of Public Health (Professor W. R. Smith, President, Sir James N. Dick, K.C.B., Surgeon-Major-General J. Jameson, C.B., Sir James R. Andrew Clark, Bart., Dr. J. C. Thresh, and Mr. C. A. James, L.R.C.P. Lond.); the Incorporated Society of Medical Officers of Health (Surgeon-Lieutenant-Colonel G. P. Bate, President, Dr. E. Seaton, Dr. F. J. Allan, Dr. W. H. Kempster, Dr. Reginald Dudfield, and Mr. H. C. Jones); the University of Dublin (the Earl of Rosse, Mr. E. H. Carson, M.P., and Mr. W. E. H. Lecky, M.P.); the Royal University of Ireland (the Marquis of Dufferin and Ava, Sir Thomas Moffett, Mr. J. C. Meredith, LL.D., and Mr. Joseph McGrath, LL.D.); and the Coroners' Society (Mr. G. F. Roumieu, J.P., Dr. G. D. Thomas, Mr. S. Hacker, Mr. Braxton Hicks, Mr. Arthur Langham, and Mr. W. Schröder). The Prince's reply to each deputation was as follows: "On behalf of the Queen, my dear mother, I thank you for your loyal and dutiful address and for the affectionate congratulations which you tender on the completion of the sixtieth year of her reign. It is a source of profound joy to the Queen to receive the expressions of devotion to her person and family which are offered by her subjects throughout the empire. She is gladdened by the

Digitized by Google

thought that the sixty years of her reign have been years of progress in knowledge and of increase in prosperity, and she prays that, by the blessing of Almighty God, she may always live in the hearts of her loving and beloved people."

THE CAMBRIAN RAILWAYS.—We have received a handbook of scenery accessible from the Cambrian Railways, "Picturesque Wales," and a "Souvenir of Wild Wales," both of which will soon dispel any doubts, should such exist, of Wales being one of the most picturesque divisions of the British Isles. Wales, however, has a stronger claim than that of beauty to recommend itself to the health-seeker and tourist, for the air is, as a general rule, of the purest and the sanitation for the most part good. There are many facilities for convenient and cheap travel given by the railway companies, and those who are yet undecided "where to go" should certainly procure these two publications from the Cambrian Railways Company's offices at Oswestry.

DIPHTHERIA IN LONDON.—The deaths registered from diphtheria in London during the week ended July 10th numbered 43, having been 29, 24, and 32 in the three preceding weeks. The corrected decennial average for the twenty-seventh week of the period 1887-96 was 36, and was thus exceeded by 7. Of the 43 deaths, 2 were of infants, 31 others of children under five years of age, and only 1 of a person aged over twenty years. Eight of the deaths belonged to Camberwell, 4 to St. George, Southwark, and 3 to Poplar sanitary area. At the close of the week there were 914 persons under isolation in hospitals on account of diphtheria, the admissions during the week having been 163 in number, against 124, 119, and 152 in the preceding three weeks. In the Outer Ring there were 5 deaths registered in the week—namely, 2 in Bexley, and 1 in Wimbledon, in Acton, and in Stratford sub-districts respectively. For the week ended July 17th the deaths registered in London were 36 in number, the corrected decennial average for the particular week having been 37. Of the 36 deaths, 4 were of infants, and other 24 of children under 5 years of age, no death being of a person aged more than 20 years. Lambeth was credited with 4 of the deaths, and Islington, Mile End Old Town, and Poplar sanitary areas each with 3 deaths. On Saturday, July 17th, there were 927 patients still under treatment in hospital, the admissions during the week having been 136 in number. In the Outer Ring the registered deaths from diphtheria numbered 8—namely, 2 in Hillingdon, and 1 each in Wimbledon, Hayes, Tottenham, Edmonton, Enfield, and Leyton sub-districts.

WORCESTERSHIRE MEDICAL SOCIETY.—The quarterly meeting of this society was held by kind invitation of Dr. Stanley Haynes (Vice-President) at his house at Malvern on July 20th, Mr. T. Bates, of Worcester, being in the chair. Three new members were elected, and six members proposed for election at the next meeting.—Dr. Mabyn Read, medical officer of health of Worcester, read a paper on "The Antitoxin Treatment of Diphtheria," relating his experiences during the epidemic that occurred in the city during 1896. One hundred and thirty-seven cases were treated by him at the Isolation Hospital, with seventeen deaths. He expressed a strong opinion as to the great value of antitoxin in the treatment of diphtheria and found no detrimental effects of any consequence due to its use.—Inspector-General Cowan, M.D. Edin., R.N., Dr. Haynes, Mr. Moore, and others joined in the discussion, and Dr. Read having replied, the President thanked him for his excellent and interesting paper.—Dr. Pollard then read a paper on "The Clinical Aspects of Adenoids." After discussing some of the less well-known symptoms he expressed his preference for chloroform as an anæsthetic and Gottstein's curette as the most generally useful instrument for the operation required for the removal of the growths.—Mr. Bates showed (1) a patient from whom he had removed a Thyroid Cyst with Calcified Walls (the specimen also was exhibited); and (2) a Testis removed by Castration, which exemplified the various results of the tuberculous process when attacking that organ.—Mr. Holbeche showed (1) a man who had suffered from Compound Dislocation of the Ankle Joint, with Compound Comminuted Fracture of the Lower Third of the Fibula, followed by Delirium Tremens and Cellulitis of the Leg and Thigh, necessitating many incisions; notwithstanding all this, the man made a good recovery, with only slightly impaired movement of the ankle-joint; and (2) two children of a family, all of whom had been affected with Mal-development of Fingers or Toes.

THE NEWPORT AND MONMOUTHSHIRE HOSPITAL.—The foundation stone of this hospital will be laid by Lord Tredegar on Aug. 2nd, when a large public demonstration will mark the event.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT.—The report and statistics of the Poplar and Stepney Sick Asylum District for the year ending Lady-day, 1897, show that during that period there were 3656 admissions into the asylum, 3134 discharges, and 582 deaths. The cost of food, fuel, light, and clothing for the paupers was £12,209, the weekly rate per head being 5*s*. 11*d*. for the first half year and 6*s*. 8*d*. for the second half year. The asylum contains 770 beds, of which 550 are allocated to Poplar Union and 220 to Stepney Union. The nursing staff consists of eight sisters, nine assistant nurses, seven staff-nurses, one superintendent night nurse, and thirty-seven probationers. The medical superintendent is Mr. Charles Spurrell, F.R.C.S. Eng.

HARROGATE ROYAL BATHS.—An important addition to the public buildings of Harrogate has been made by the erection of the new baths, a handsome structure which has required about three years for completion. The Queen has graciously permitted the corporation to call it the Royal Baths, and it was formally opened on July 23rd by H.R.H. the Duke of Cambridge, who described the springs and the new buildings whereby their general use is so much facilitated as being advantageous, not only to the neighbourhood, but to the whole of England. The corporation naturally take the utmost interest in the success of this extension of the resources of the place, as was acknowledged by the Mayor, who stated that the suite of baths had been erected for the purpose of meeting the growing demands for the special modifications of bathing (including massage) introduced in recent years. The ground floor of the building contains the central hall or pump room, the gentlemen's baths, the ladies' baths, the general rooms, and the winter garden, the latter of which is 183 feet long, 42 feet wide, and 35 feet high under the glass roof. The Turkish bath, of course, requires a series of rooms, which are thoroughly well suited to their purpose and provided with every requisite. Beyond it is the "inhalation" room, the special feature of which is a sulphur water fountain rising in the middle, and giving off a vapour or fine spray which is inhaled by the occupants of the apartment. In the "pulverisation" room medicated water can be applied to the throat, eyes, &c. Among the other varieties of baths may be mentioned several kinds of douche baths, slipper baths, needle baths, the Harrogate combination bath, and the vapour-room, which is sometimes called a Russian bath. In the well-bath the water is deep enough to reach to the neck of a person standing upright. The crane-bath is one in which the bather is taken from an invalid chair and lowered into the water by a lift. The building is entirely lighted by electricity and heated by steam. It would appear that, owing to the public spirit and enterprise of the Harrogate Corporation, invalids in this country will be able to avail themselves of the most recent improvements in the application of baths to the treatment of disease without undergoing the fatigue and anxiety of a journey to some Continental health resort.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health (Scotland) Bill.

THE medical profession scored a notable victory on the report stage of this Bill. In its original form the Bill provided for proceedings being taken by the local authority when nuisances were reported to it by the medical officer, but in the Grand Committee the sanitary inspector was added, this putting the medical officer and the sanitary inspector on the same level with regard to the certification of nuisances. On the report stage the Lord Advocate proposed as a compromise that the proceedings should be "upon a certificate by the medical officer, or after a report by the sanitary inspector, or otherwise." Sir William Priestley, Sir Walter Foster, and Sir Charles Cameron pressed the Lord Advocate to leave out all reference to the sanitary inspector, and they were so successful in their representations that the Lord Advocate agreed to withdraw his amendment, and to accept one in the name of Sir William Priestley leaving the local authority full discretion as to the steps they should take before instituting proceedings. Another

Digitized by Google

success was gained in connexion with Clause 45, which gives power to inspect premises where infectious disease is supposed to exist. Captain Sinclair moved to omit the power given to the sanitary inspector to enter and inspect. Dr. Clark insisted that this was giving the sanitary inspector power to diagnose disease, and several of the other medical members supported him. Sir Walter Foster expressed the view that the sanitary inspector should only enter the premises under the direction of the medical officer. In the end the Government decided to make the matter an open question, and on a division Captain Sinclair's motion was carried by 110 to 82 votes.

Indian Famine and Plague.

Sir William Wedderburn has given notice that in connexion with the Indian Budget he will ask the House of Commons to express the opinion "that a detailed and searching village inquiry should be instituted, in order to ascertain the causes which blight the industry of the cultivators and render them helpless to resist even the first attacks of famine and pestilence."

Withdrawal of the Lunacy Bill.

The Bill to amend the Lunacy Law got through all its stages in the House of Lords, but when it reached the House of Commons notice of opposition was given by Sir Henry Fowler, and in consequence Mr. Balfour at once withdrew the measure, saying that in the circumstances there could be no hope of passing it during the present session.

HOUSE OF LORDS.

FRIDAY, JULY 23RD.

London University Commission Bill.

The Duke of Devonshire moved the second reading of this Bill and said that it was substantially the same measure as that which passed last session through their lordships' House, but for which, unfortunately, time did not suffice in the House of Commons. Certain modifications had been introduced which were the result of communications which had been in progress during almost the whole of the session between those interested, and there was reason to hope that the difficulties which prevented the Bill from passing into law had been removed, and that it would pass now as practically an unopposed measure. He was sorry to say that very considerable time had elapsed since Lord Cowper's Commission reported, and during that time a very great change, he was happy to say, had taken place in the higher education of the City of London, and this had caused the necessity for certain alterations of procedure in the Bill. Almost the only point discussed in the House last year was that which affected, or was supposed to affect, denominational colleges, and principally King's College. The agreement which was arrived at last year had been embodied in somewhat different terms in the present Bill, and he believed it was now practically accepted by King's College and the principal bodies concerned, and was now not objected to by Lord Herschell, who took a strong line of opposition last year.—The Earl of Kimberley, after making some comments on the Bill, expressed the hope that it might be passed into law before the close of the present session.

HOUSE OF COMMONS.

THURSDAY, JULY 22ND.

Beri-beri in Ireland.

Mr. Carew asked the Chief Secretary to the Lord-Lieutenant of Ireland whether any, and what, steps were being taken to check the spread of beri-beri in the Richmond Lunatic Asylum. Was he aware that the disease originated in long overcrowding and that though the inspectors of lunatics as far back as 1891 made a special report to the governors complaining that the Board of Control had taken no action to meet in any way the urgent requirements of the institution with its vast population for increased accommodation, nothing had been done to meet the requirements beyond the erection of a few wooden sheds at the Richmond Asylum and a few temporary structures at Portrane, both condemned as insanitary and insufficient by Dr. Manson and Sir Thornley Stoker? And whether the first section of the permanent structure which the Board of Control was erecting at Portrane would not be available till March, 1899? and, if so, what steps would be taken in the meantime to relieve the congestion?—Mr. Gerald Balfour replied: The outbreak of beri-beri in the Richmond Asylum has been fostered by overcrowding, consequent on the rapid increase in the number of patients. Steps have been taken to meet this overcrowding by erecting temporary accommodation at the asylum, and also at Portrane, county Dublin. The patients attacked have, as far as possible, been isolated, and the buildings occupied by them have been disinfected. The present outbreak is, so far, of a very mild type. There has been only one death attributed to it, and the general death-rate of the institution was never lower. The disease, though fostered by overcrowding, does not, it is believed, originate *de novo* from that cause, at least in this climate. The inspectors of lunatics did not make any complaint in 1891 that the Board of Control had taken no action to meet the urgent requirements of the institution for increased accommodation; but in their first memorandum of inspection they called the special attention of the Board of Governors to the overcrowding, and discussed the question of how increased accommodation could best be provided. Consequent on the reports of the inspectors numerous conferences were held between the Board of Control and the Board of Governors, and it was ultimately decided to build a new and fully equipped asylum to accommodate 1200 patients at Portrane. This asylum is now in course of erection, and it is anticipated that the first portion of it will be ready for the reception of patients in about twelve months. In addition, temporary accommodation has been provided at the Richmond Asylum for 298 patients, and at Portrane for 224, and further buildings are now being erected, which, it is anticipated, will make the total accommodation sufficient for the numbers at present in the asylum. The inspectors state that they are of opinion that these temporary buildings have been erected with the greatest care, and with every precaution that sanitation requires, and that they are similar to those erected recently at the London County Asylums to provide temporary accommodation.—Mr. T. M. Healy asked whether the right hon. gentleman would consider the desirability of getting a specialist to examine into and report upon this strange disease, or whether the right hon. gentleman had already obtained the opinion of a specialist with regard to it.—Mr. Gerald Balfour: I am under the impression that a specialist did visit the asylum and did report upon the disease, but the actual cause and origin of the outbreak still remains obscure.—Mr. T. M. Healy asked whether that document was public property.—Mr. Gerald Balfour: I am not quite certain on the point, but I will make inquiries with regard to it.

FRIDAY, JULY 23RD.

Medical Students and the Soudan.

Captain Norton asked the Under Secretary of State for War whether the War Office had already taken steps to obtain from the medical schools students who had not completed their studies with a view to the formation of an ambulance corps for service in the Soudan, or whether any such steps were in contemplation.—Mr. Brodrick: No force is being prepared in this country for service in the Soudan.

Candidates for the Army Medical Staff.

Mr. Brodrick, in reply to Captain Norton, said there were twenty-seven candidates for the next Army Medical Staff examination.

State of the Indian Army.

Captain Pirie asked the Under Secretary of State for War whether the War Office would be prepared to reconsider the question of long service in India for British troops, as being both physically and financially advantageous, especially in view of the disastrous casualties from enteric fever and venereal disease among British soldiers in India. Mr. Brodrick replied that the application of the short service system to India had been proved to possess many advantages from a physical, financial, and military point of view, and Her Majesty's Government had no intention of reverting to the old system of long service for the Indian Army.

Small-pox Hospital Sites.

Dr. Tanner asked the President of the Local Government Board whether any definite rules now apply in the selection of sites for hospitals for small-pox, and if any evidence was now available to indicate at what distance from people aggregated in institutions or living in dwelling-houses hospitals might be established without risk to persons who were susceptible of small-pox infection.—Mr. Chaplin replied: The inquiry of the hon. member raises an interesting and important question, on which he is probably more competent to express an opinion than I am, but I am advised by the medical experts of the Local Government Board that no definite evidence is as yet available to show what is the distance at which small-pox hospitals may be established from aggregations of persons without risk to such persons, and pending the solution of this question we do not sanction loans for the provision of small-pox hospitals on any site where it would have within a radius of a quarter of a mile either a hospital or a workhouse or any similar establishment, or a population of 150–200 persons, or on a site where it would have within a radius of half a mile a population of 500–600 persons, whether in one or more institutions or in dwelling houses.

The Certification of Lunatics.

Dr. Tanner asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in the case of any dangerous lunatic confined in an asylum, in whose behalf application had been made that he or she should be discharged, having ceased to be insane, such application could not be entertained until it was certified to the Lord-Lieutenant by two physicians or surgeons that the individual had become of sound mind, or it had been certified by the resident medical superintendent or visiting physician that he had ceased to be dangerous, and if in the case of the two former authorities demanding such release any demur on the part of the local medical (asylum) authorities could prevent it.—Mr. Gerald Balfour replied: In the case of a dangerous lunatic committed to a district asylum under the 10th Section of the Act 30 and 31 Vict., Cap. 118, it is not necessary for two physicians or surgeons to certify that the individual has become of sound mind before an application for discharge can be entertained. The discharge of such lunatics is regulated by Section 11 of the Act and by the latter part of Section 10. Section 11 requires the resident medical superintendent or the visiting physician to certify that the person has either become of sound mind or has ceased to be dangerous, while the latter part of Section 10 enables relatives or friends under certain conditions to take the lunatic under their care and protection on entering into sufficient recognisances for his safe keeping. But the Court of Appeal has held that there is no absolute right conferred by this Section, and that it remains optional with the governors of the asylum to so transfer the custody of the lunatic.

MONDAY, JULY 26TH.

The Pollution of the Brent.

Mr. Bartley asked the President of the Local Government Board whether he was aware that the present condition of the River Brent was again in a most dangerous condition to the health of the district and of the western suburbs of London, and that residents who could were leaving their houses in consequence, and that the children in the large central district school, some 1200 in number, which was close to the banks of the River Brent, were in great danger from the foul condition of the stream; whether his attention had been drawn to the correspondence between the Hanwell and other local authorities on the subject; whether anything had been done to protect the population since attention was called to the matter in this House; and whether he would cause immediate steps to be taken to stop the pollution of the river.—Mr. Chaplin replied that he was not aware of the correspondence between the Hanwell and other local authorities referred to, and the only complaint which he had received for many months past as to the condition of the Brent was received on the 20th of the present month from the Wembley Urban District Council alleging pollution of the river by sewage from Willesden district. Since attention was called to the matter in this House, an injunction had been granted to restrain the Willesden Urban District Council from discharging the effluent from their sewage works into the river until it had been properly purified. An injunction had also been obtained against the Wembley District Council. In the case of Willesden the Local Government Board had sanctioned loans amounting to £23,000 for sewerage and sewage disposal and £12,000 for the

Digitized by Google

purchase of an additional area of fifty-two acres of land for the purification of the sewage. They had also sanctioned a loan of £5000 for the purpose of sewage disposal in the case of the Wembley district. The Middlesex County Council were empowered to enforce the provisions of the Rivers Pollution (Prevention) Act and any action which might be required as regards other districts could be taken by them. The Local Government Board were not empowered to institute proceedings

The Vaccination Commission.

Sir Seymour King asked the President of the Local Government Board whether he had yet ascertained when the remainder of the evidence and special reports on which the final reports of the Royal Commission on Vaccination was based would be published, and what was the cause of delay.—Mr. Chaplin said that Mr. Bret Ince, who acted as secretary to the Commission, informed him on May 12th that the whole of the as yet unpublished evidence referred to would be issued within three weeks of the time, and that the special reports would be issued at the same time, but some of them rather sooner than the evidence. He had since then twice written to Mr. Ince on the subject of the delay, but he regretted to state that as yet he had not received any reply to his last communication, which was dated July 14th, or to the memorandum which was forwarded to him on Saturday, when the notice of this question appeared on the paper.

Inflammable Preparations for the Hair.

Mr. Wootton Isaacson asked the Home Secretary whether his attention had been called to the death by fire, of a lady in a hairdresser's shop, while having her hair dressed with a preparation known as Petrole or dry shampoo; whether he was aware that this dangerous preparation was composed of rectified petroleum and ether, which gave off a vapour which would catch fire from a distant light, or the action of the sun; and whether he would adopt means to put a stop to the sale of these dangerously inflammable preparations.—Sir M. White Ridley replied: Yes, my attention has been called to this accident. I am informed that the inquest has been adjourned for further evidence as to the precise character of the preparation and other matters, and I am unwilling to anticipate the conclusions of the jury by expressing any opinion at present either as to the cause of the accident or as to the necessity which it may show to exist for taking further measures with regard to substances of this character. If, however, it is found, as seems likely, that the preparation was largely composed of petroleum spirit it falls, of course, within the provisions of the Petroleum Acts. I may add that the London County Council, as the local authority under those Acts, are giving careful attention to the subject, and are represented at the inquest. The hon. member is no doubt well aware that the present law with regard to petroleum is in a very unsatisfactory state.

TUESDAY, JULY 27TH.

Calf Lymph.

Mr. Strachey asked the President of the Local Government Board whether a board of guardians might instruct the public vaccinators in their union to give parents the option of having their children vaccinated with calf lymph instead of human lymph.—Mr. T. W. Russell, who replied on behalf of Mr. Chaplin, said that the public vaccinators were not subject to the directions of the boards of guardians in this matter, but they were enabled by the instructions of the Local Government Board to use calf lymph instead of human lymph whenever they so desired.

WEDNESDAY, JULY 28TH.

Infant Life Protection Bill.

At this sitting this Bill as amended by the Grand Committee was considered and was read a third time. It now only awaits the Royal Assent before becoming law.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ABERNE, J. L., L.K.Q.C.P. Irel., L.R.C.S. Edin., has been appointed Medical Officer for the Gislingham Sanitary District of the Hartismere Union.

ANDERSON, J. A., M.D. Glasg., has been appointed Medical Officer for the Leswalt (Stranraer) Parish Council, vice H. Cochrane.

ATKINS, T. B., L.A.H. Dub., has been appointed a Member of the Licensing Court for the Licensing District of Mitchell, New South Wales.

BLUMFIELD, J., M.D. Cantab., has been appointed Junior Anæsthetist to St. George's Hospital, London.

CLUCKIE, A., M.B., C.M. Glasg., has been appointed Medical Officer for the Stranraer Parish Council.

COLE, S. G., M.B., B.Ch. Oxon., has been appointed Junior Obstetric Officer to St. Mary's Hospital, London.

GREENWOOD, ALFRED, M.B., Ch.B. Vict., L.R.C.P., L.R.C.S. Edin., has been appointed Resident Medical Officer to the Salford Union Infirmary, Manchester.

HUNT, T. H., M.B., B.S. Lond., has been appointed Senior House Surgeon to the Royal Halifax Infirmary, vice J. C. Maxwell, resigned.

KEMPE, C. M., M.R.C.S., has been re-appointed Medical Officer of Health for the Shoreham Urban Sanitary District.

LAWSON, THOMAS, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Resident Medical Officer for the St. Pancras and Northern Dispensary, Euston-road, London.

MCARTHUR, D. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 5 Sanitary District of the Hertford Union.

MULLIN, JOHN, L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Ruskey Dispensary District, Strokestown Union.

NEIL, JAMES, M.D. Aberd., C.M., has been appointed Medical Superintendent for the Warneford Asylum, Oxford.

PAKES, WALTER C. C., L.R.C.P. Lond., M.R.C.S., D.P.H. Camb., has been re-appointed Assistant Demonstrator of Bacteriology at Guy's Hospital, with the Charge of the Practical Chemistry in the D.P.H. Course.

RICHARDS, J. S., M.D. Lond., B.S., L.R.C.P., M.R.C.S., has been appointed Medical Superintendent of St. Saviour's Infirmary, East Dulwich-grove, S.E., vice H. E. Harris, resigned.

ROSE, H., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Buckinghamshire County Hospital, Aylesbury.

SALMON, C. C., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been elected a Member of the Dental Board of Victoria, Australia.

SPRINGTHORPE, J. W., M.D., Ch.B. Melb., M.R.C.P. Lond., has been appointed President of the Dental Board of Victoria, Australia, vice Dr. Turner, resigned.

STORR, F. A., B.A. Oxon., L.S.A., has been appointed Medical Officer of Health by the Halifax Rural District Council.

TAYLOR, J., M.D. Aberd., D.P.H. Camb., has been re-appointed Medical Officer of Health by the Chester-le-Street Rural District Council.

VAUGHAN, ETHEL, M.B., B.S. Lond., has been appointed an Assistant Medical Officer to the Camberwell Infirmary.

WILKINSON, WM. A. HORSLEY, M.B., Ch.B. Vict., has been appointed Medical Officer of Health to the Gainsborough Urban District Council, vice D. Mackinder, resigned.

WILLIAMS, R. T., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health for the Porthcawl Urban Sanitary District.

YOUNGSON, T. McK., M.B., C.M. Aberd., has been appointed Medical Officer of Health by the Wolstanton Rural District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Senior House Surgeon. Salary £80, with board and washing.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House Surgeon. Rooms, coals, and lights provided.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W. — Clinical Assistant.

CHILDREN'S HOSPITAL, Nottingham. - House Surgeon (non-resident) for six months. Salary at the rate of £100 per annum.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, increasing £10 yearly to £120 a year, with board, lodging, &c.

CUMBERLAND INFIRMARY, Carlisle.—House Surgeon for one year. Salary £70 per annum, with board, lodging, and washing.

GUEST HOSPITAL, Dudley.—Resident Medical Officer. Salary £100 a year, increasing £10 a year to £120, conditionally, with board, residence, attendance, and washing.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Junior Resident Medical Officer for six months. Salary at the rate of £50 per annum, with board, lodging, and washing.

HUNTINGDON COUNTY HOSPITAL, Huntingdon.—House Surgeon. Salary £50.

LANCASHIRE ASYLUMS BOARD.—Medical Attendant on the Patients for the Idiot Boys' Asylum at Winwick, near Warrington. Inclusive salary 100 guineas per annum. Applications to the Clerk to the Lancashire Asylums Board, County Offices, Preston.

MALDON UNION.—Medical Officer for the St. Peter's Medical Relief District. Salary £80 a year, with midwifery fees of 15s. per case and other extra fees. The Medical Officer will also be appointed Public Vaccinator. Salary and fees subject to deduction under the Poor Law Officers Superannuation Act. Applications to the Clerk to the Board, Maldon, Essex.

MANCHESTER ROYAL INFIRMARY, DISPENSARY, AND LUNATIC HOSPITAL OR ASYLUM.—Honorary Dental Surgeon.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officer at the North-Eastern Fever Hospital, St. Anne's-road, Tottenham, N., unmarried. Salary £160 the first year, £180 the second year, and £200 the third and subsequent years of service, with board, lodging, attendance, and washing, subject to deduction under the Poor-law Officers Superannuation Act, 1896. Applications to the Clerk to the Board, Chief Office, Norfolk-street, Strand, W.C.

PARISH OF BOLESKINE AND ABERTARFF.—Medical Officer for the Fort-Augustus District. Applications to Mr. A. Urquhart, Inspector of Poor, Gorthleck.

POPLAR HOSPITAL FOR ACCIDENTS, Blackwall, E.—Two Assistant House Surgeons for six months. Salary £65 a year, with board and residence.

ROTHERHAM HOSPITAL AND DISPENSARY.—House Surgeon for three years. Salary 100 guineas, with board, lodging, and washing.

ROYAL SURREY COUNTY HOSPITAL, Guildford. — Assistant House Surgeon. Board, residence, and laundry provided.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, London.—Demonstrator of Anatomy.

STOCKPORT INFIRMARY.—House Surgeon. Salary £100 a year, with board, washing, and residence. Also Junior Assistant House Surgeon for six months. Honorarium at the rate of £24 per annum, with residence, board, and washing.

Digitized by Google

STOURBRIDGE DISPENSARY.—House Surgeon and Secretary. Salary £120 a year, increasing £5 annually to £130, with furnished rooms, coal, and gas, and an allowance of £25 for travelling expenses.

Births, Marriages, and Deaths.

BIRTHS.

BARRACLOUGH.—On July 24th, at London-road, South Lowestoft, the wife of Harold C. Barraclough, M.B., of a son.

CHAPMAN.—On July 20th, at St. John-street, Hereford, the wife of Paul Morgan Chapman, M.D., F.R.C.P., of a son.

GARDINER.—On July 26th, at Portland-terrace, Richmond, Surrey, the wife of M. H. Gardiner, M.B., L.R.C.P., L.R.C.S. Edin., of a son.

LAWSON.—On July 25th, at Fortune's Well, Portland, Dorset, the wife of David James Lawson, M.D., of a son.

NORTON.—On July 26th, at Kennington-park-road, S.E., the wife of H. Harvey Norton, L.R.C.P., M.R.C.S., of a daughter.

SHUTE.—On July 22nd, at Granby-place, Northfleet, the wife of G. S. Shute, M.D., of a son.

THOMPSON.—On July 23rd, at Grenville House, Quay, Bideford, N. Devon, the wife of Charles Sinclair Thompson, M.B. Edin., of a son.

MARRIAGES.

BOND—YELD.—On July 22nd, at St. Mary Abbott's, Kensington, William Ernest Bond, M.R.C.S. Eng., L.R.C.P. Lond., of Bramhall, Cheshire, to Emily Hollier Yeld (Millie), younger daughter of the late W. Walter Yeld, of Churchgate House, Stockport.

CRICKMAY—ROSSER.—On July 22nd, at St. John's Church, Croydon, by the Rev. William Henry, M.A., Vicar of Challock, Kent, godfather of the bride, assisted by the Rev. T. G. Hill, M.A., Colin Lindsay, youngest son of George R. Crickmay, F.R.I.B.A., of Putney and Westminster Chambers, to Edith Lizzie, only child of Walter Rosser, M.D., of Croydon.

CURREY—BINNY.—On July 24th, at St. Peter and St. Paul's, Aldeburgh, E. F. N. Currey, M.R.C.S. Eng., L.R.C.P. Lond., eldest son of the late J. E. Currey, M.D., of Lismore, Co. Waterford, Ireland, to Constance Murray, fourth daughter of Major-General Binny, B.S.C. (Retired), of Crespigny, Aldeburgh, Suffolk.

DUCAT—JACKSON.—On July 17th, at St. Mary's, Spring-grove, Isleworth, Arthur David Ducat, M.B. Lond., of Chiswick, to Helen Meltora, eldest son of Walter H. E. Jackson, C.C., of Derby House, Spring-grove, Isleworth.

GIBSON—WATT.—On July 26th, at St. John's-wood Presbyterian Church, Marlborough-place, Henry W. Gibson, M.B., to Jane Grant, eldest daughter of A. P. Watt, 29, Abbey-road, N.W.

GLOVER—GLOVER.—On July 22nd, at Union Chapel, Islington, by the Rev. Richard Glover, D.D., of Bristol, and the Rev. W. Hardy Harwood, of Islington, Lewis G. Glover, M.A., M.D. Cantab., of 1, College-terrace, Hampstead, youngest son of John Glover, J.P., of Highgate, to Mary Mildred, only daughter of James Grey Glover, M.D., J.P., of Highbury.

NEWTON—HARBORD.—On July 22nd, at Slaugham Church, Sussex, Reginald Frederick Henry Newton, M.R.C.S., L.R.C.P., of Balcombe, Sussex, to Susanna Booth, fourth daughter of the late William Harbord, Surgeon, Wainfleet All Saints, Lincolnshire.

STRAND—PETTER.—On July 21st, at St. Michael's, Blackheath-park, Alick Oondell Strand, M.R.C.S., L.R.C.P., L.D.S., Hinckley, to Edith, eldest daughter of Arthur Petter, Eskdale Lodge, Blackheath, S.E.

TOWNE—NEWNHAM.—On July 27th, at Lady Grey, Allival North, South Africa, by the Rev. W. Rossiter, Rector of St. Paul's, Allival North, Hugh Rose Forster Towne, M.R.C.S., L.R.C.P. Lond., younger son of the Rev. L. B. Towne, Vicar of St. John the Baptist, Harlow, to Ethel Agnes, second daughter of Dr. Lewis J. Newnham, of Lady Grey.

WILSON—NAYLOR.—On July 21st, at Cairo, Williams Hawkins Wilson, M.B. Oxon, Professor of Physiology, Medical College, Cairo, to Kate Hamilton, youngest daughter of J. B. Naylor, C.S.I., Indian Civil Service (Retired), of Cadbury House, Yatton, Somerset.

DEATHS.

BLACK.—On July 19th, suddenly, at 95, Goldhawk-road, London, W., John Frank Black, M.B., C.M., aged 31 years.

BULLOCK.—On July 21st, suddenly, Thomas Warren Bullock, M.R.C.S., L.S.A., of Overtown House, Isleworth, aged 37 years.

HOLMAN.—On July 18th, at his residence, Niton, Isle of Wight, Charles Henry Holman, M.R.C.S., aged 75 years.

OAKES.—On June 14th, 1897, in his 27th year, George Nelson Davidge Oakes, L.R.C.S.I. and L.R.C.P.I., of 28, Leeson-park-terrace, Leeson-park, Dublin, accidentally drowned while bathing at Menaos, N. Brazil, while in Medical Charge of the s.s. *Sobraleuse*, Red Cross Line, to the intense grief of his afflicted mother, relatives, and many kind, sorrowing friends: only son of the late John Oakes, Esq., Lieutenant, Deputy-Assistant-Superintendent of Stores. (By cablegram, June 19th.)

ROBERTS.—On July 24th, at Uxbridge-place, Carnarvon, Watkin William Roberts, F.R.C.S., J.P., in his 79th year.

THOMPSON.—On July 22nd, at Welbeck-street, London, Henry Thompson, M.D., Senior Fellow of St. John's College, Cambridge, F.R.C.P., aged 81 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

PRESERVATION OF DEAD BODIES.

ACCORDING to Dr. Kraindel (*Vrach*, No. 27, 1897) a very efficient method of preserving bodies for anatomical and other purposes is to inject into the vessels a 5 per cent. solution of formalin to the extent of a quarter or even a third of the weight of the body. From experiments made on the body of a child, and on a head and foot, he came to the conclusion that a temperature of 80° F. has no effect on bodies so treated—at all events for six or seven weeks. The cadaveric discolouration and all smell disappeared as soon as the liquid had been introduced, and the external appearance became that of a body recently dead. Experiments made with a stronger solution—10 per cent.—showed that this causes decided external change, the skin having a shrivelled appearance and becoming slate-coloured in less than three weeks.

WHAT'S SAUCE FOR THE GOOSE, &c.

AT the recent election of an assistant physician to the Carlisle Infirmary the rules of the institution were read, and the attention of the new member of the staff was specially directed to a statute preventing union appointments or clubs being held by the honorary staff, to which reasonable ordinance he was asked to subscribe. A correspondent who should be well informed tells us that an assistant surgeon also elected recently holds club appointments, and he asks: "Is this fair?" If the facts are as he has stated them, undoubtedly the position is not fair at all, and we recommend the assistant surgeon to resign his club appointments, if he have any, so as to bring himself into line with his medical *confrère*.

Ed. S., *C.M.*—The duties of a workhouse medical officer are set forth very fully in Article 205 of the General Consolidated Order of the Poor Law Commissioners, dated July 24th, 1847. There have been some minor amending orders issued by the Local Government Board since then, but practically this General Order gives full particulars and has all the authority of a statute. The duties of master, matron, and nurse are set forth in the same Order, and the duties of the first two named were somewhat modified by a General Order of the Local Government Board, dated Feb. 12th, 1879, and by supplementary Orders at other times. The standard text-book on the subject, which we commend to the notice of our correspondent, is "Glen's Poor-law Orders" (Knight and Co.), costing about 25*s*. The General Orders can be obtained separately from Messrs. Eyre and Spottiswoode, East Harding-street, London. As regards the duties of nurse, it is with much regret we record that no material modification has been made in her duties since the Order of 1847, although times have changed so much in this department of human enterprise. However, we understand that the Local Government Board have at the present moment under consideration a new Order dealing with the question of workhouse nursing.

THE PATHOLOGY OF DISTEMPER.

To the Editors of THE LANCET.

SIRS,—The pathology of distemper in the dog has been neglected, I suppose, by the veterinary surgeons, as the disease is very prevalent and claims a great number of very valuable dogs by death. I have hunted in vain to find if any micro-organism is described, and have also consulted some local veterinary surgeons. Klein in his latest work does not describe distemper at all. I should define distemper as an acute inflammatory, contagious disorder, affecting chiefly the respiratory passages, sometimes the alimentary tracts, and very frequently leaving as a sequela some nervous affection (chorea and paralysis and fits), rheumatism, and rickets. Distemper in the dog, I think, is only a stage in the life-history of the organisms of scarlet fever and diphtheria, for these reasons scarlet fever is followed by rheumatism and dropsy and chorea in the human being. So it is in the dog with distemper. Diphtheria is frequently followed by paralysis. So also is distemper in the dog. In the dog the paralysis is chiefly in the hind limbs, but I have seen the throat also affected. As regards treatment in these animals, perchloride of iron gives very good results. Antitoxin injected gives excellent results also, the nasal mucous membrane is cleared of its discharge in twenty-four hours, and should there be a white film over the eyes this also disappears. But for this film calomel dusted into the eyes has given me excellent results.

Vaccination between the ears has also given me good results. The other part of the treatment I follow is a stimulating plan—plenty of raw meat-juice, eggs and milk, and port wine and brandy—and hygienic. The sequelæ of distemper are almost incurable—viz., chorea and paralysis. I write this short letter so that some of our bacteriologists may take up this subject and see if there is any connexion between these diseases pathologically, as they coincide clinically. I believe there is. Most of my experiments with antitoxin and vaccination have been done on high-bred dogs—i.e., in-bred to bring out their fine qualities. Mongrels do not suffer so severely as in-bred ones.

I am, Sirs, yours truly,

Ashton-under-Lyne, June 14th, 1897. F. W. MANN, M.B.Edin.

*** Were distemper due to the microbe of scarlet fever would not our correspondent expect the latter disease to be specially rife among veterinary surgeons, the attendants at kennels, &c.? But we have yet to learn that such is the case. Diphtheria, on the other hand, is due to a perfectly well-known bacillus, which during the past twelve years has been carefully studied by Löffler, Roux, Yersin, and others, but which has never, so far as we are aware, been shown capable of producing symptoms even remotely resembling those of distemper. Further than this, Friedberger and Fröhner (two very eminent German veterinary authors) absolutely deny that any case of human diphtheria has been shown to have arisen from animal infection, or that human diphtheria can be transmitted (as a specific disease) to animals. The micro-organism of distemper has not yet been definitely identified, though our correspondent is quite in error in supposing that the veterinary profession has neglected to study the disease. On the contrary, it has given it very close attention. Millais identified six varieties of organism with nasal discharge, one of which was a bacterium and the other five cocci. Of these one resembles very closely the pneumococcus of Friedländer, and is regarded by Millais as the *causa causans*, on account of its occurring in the blood of every animal examined. By growing mixed cultures on gelatin (transplanting to new tubes six or seven times) a material was produced which could be employed as vaccine. It sufficed to smear a small quantity of such a culture on the nose of a well-bred dog to bring about a mild and uncomplicated attack of distemper, after which the animal enjoyed an immunity similar to that which follows disease contracted in the usual way. Rabe (of the Hanover Veterinary School) found small cocci, sometimes in chains, sometimes aggregated in twos or fours (sarcinæ), in the nasal discharge and blood. They stained readily with methyl-violet. Friedberger confirmed this. Mathis discovered a diplococcus which, after cultivation, reproduced the disease in dogs. Schantyr recently published a report of experiments. He divides distemper into three forms—viz., an abdominal "typhus" type, distemper proper, and canine "typhoid." The "typhus" bacilli are small, short bacilli closely resembling those of human typhus. They occur in the blood and internal organs. The true distemper bacilli are small, slightly bent organisms, and the "typhoid" bacilli are very small, straight rods, usually aggregated together in groups.—ED. L.

TRENCH'S REMEDY.

WE have received a curious little pamphlet issued by Mr. J. Townsend Trench. This gentleman is the son of the late Stewart Trench, who wrote "Realities of Irish Life"—a very delightful book. The present Mr. Trench is a many-sided genius—land agent, lay preacher, magistrate, unqualified practitioner, and a crack shot like his father, who had the reputation of being sure of a crow on a bush at forty yards. We do not quite understand Mr. Trench's attitude. He advertises all his remedies—some twenty-eight in number—and apparently goes about the country prescribing gratis, and yet he says: "Never hesitate to consult your local doctor. He has the advantage of seeing you on the spot. Never for a moment let me stand between the patient and what is believed to be his or her best interest. The doctors are my best friends, and I cannot speak too highly of them and their noble profession." The "epilepsy remedy" which appears to be Mr. Trench's sheet anchor is, we fancy, a very ordinary bromide mixture; but, as Mr. Trench so truly remarks, "In some cases I find Folly harder to cure than Fits," and a much advertised and bepuffed remedy with testimonials from the clergy and ministers of all denominations will always be popular.

Dr. A. Arany (Hungary).—There is no legal obstacle to anyone practising in England with any or no qualification at all, but such person cannot sign a death certificate or sue for fees. To have any rights he must be possessed of a registrable qualification, and register such at the office of the General Medical Council. A Hungarian diploma is not registrable in this country, but the Conjoint Examining Board admits gentlemen, possessed of qualifications entitling them to practise in their own country and given after a course of study and examination equivalent to that prescribed by the Board, to the examinations for the conjoint diploma under special conditions. For further particulars we advise our correspondent to apply to the secretary of the Conjoint Board, Examination Hall, Victoria Embankment, London.

THE DROWNING FATALITIES.

WAR has been defined as an epidemic of wounds and injuries, and this particular season of the year is usually marked by its little recurring epidemic of drowning. That is only to be expected, perhaps, during the bathing and boating season; but it is seldom that so many separate cases of drowning have occurred in a short time as have recently been chronicled in the daily papers. Most of these cases have arisen under circumstances that did not admit of being foreseen in any way and provided against by the presence of a boat—a precaution commonly taken where a number of people are daily bathing at a seaside place; and one of the sad features on the present occasion has been the number of those who have been drowned whilst endeavouring to succour and save others from that fate. Drowning people proverbially catch at a straw, and a panic-stricken victim instinctively clutches at the nearest part—the head and neck, for instance—of anyone attempting his rescue. It requires much coolness and some practised skill on the part of a swimmer going to the aid of a drowning person to safely and successfully accomplish his object.

The Graduation Address

Delivered in the University of Glasgow on July 22nd, 1897,

BY W. T. GAIRDNER, M.D. EDIN. AND DUB., F.R.C.P. EDIN. AND IREL., LL.D., F.R.S.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW; PHYSICIAN IN ORDINARY TO HER MAJESTY THE QUEEN IN SCOTLAND.

LADIES AND GENTLEMEN,—I had occasion some years ago to encounter what I have selected as the text of this little sermon, or address, in a form which I venture to think is susceptible of improvement—demanding, in fact, what, if it were a Biblical text, we should call a "revised version." As it is only, however, a very common French proverb, we may take it upon ourselves now to adopt it with the rendering most suitable for our purpose. I was standing, on the occasion referred to, in the reception-room of the British Medical Association, while one friend, locally familiar with the ground, was inquiring for tickets for some evening entertainment or other, while another friend, a very distinguished ethnologist, and I were awaiting the result. The first friend was by this time pretty well merged in a crowd, all alike clamorous for tickets, on which he ejaculated incidentally, "Ah, everything comes to him who waits." "I beg your pardon," I remarked, "you will not say that if the tickets are all done and you find you cannot get them." "How do you reconcile that proverb," said the ethnologist to me, "with Shakespeare's 'tide in the affairs of men that, taken at the flood, leads on to fortune'?" "Oh," I replied, "I do not see any difficulty there; but our friend has quoted the proverb wrongly." "How so?" "The proverb, as I understand it in French, does not promise anything at all to the man who merely waits, but everything to the man who *knows how to wait*." And the distinction here is all-important; for Shakespeare's "tide" is just as likely as not to submerge the man who, like Dickens's Micawber, is merely waiting for "something to turn up," while it "bears on to fortune" only the man who "knows how to wait"—who is not merely waiting, but is ready and fully equipped and armed to take the advantage of the tide when it comes. The proverb, therefore, is all right in its real and original form, and Shakespeare is also all right; and both of them contain a good deal of the philosophy of human life and of human effort which it may well be worth while for all of us to consider a little on the present occasion. For, graduates, I am afraid it must be admitted, for most of you at least, that a good deal of "waiting" will have to be done, now or later, before you can expect to reap the highest rewards of your profession. It will not be given to many of you, as to a very excellent hospital assistant of mine now in Johannesburg, to be pitchforked at once into a share of a practice worth several thousands a year, and likely to be largely increased. You will have to wait, most of you, perhaps all of you, for considerable success in your profession; and you may have to wait longer than you quite like. But as this waiting has got to be done—as it is part of the game, in short, and, as I hope to show you, a very important and even beneficent part of it—my lesson to you is that it is as well to study how you can play this waiting game scientifically and practically, according to the laws of the game. My lesson to you is that you should not fret or worry over this, but rather be well advised about it beforehand; in other words, and in the words of the proverb, that you should "know how to wait."

"*Tout vient à point à qui sait attendre.*" That, I believe, is the true original form of the proverb, and, as you will easily see, it contains a far deeper philosophy of life than the current English version, even if we admit that the latter has any meaning at all for us, or is not absolutely misleading. "Waiting" is here set forth as a part, and a very important and necessary part, of the art of success in life; it is to be studied as a branch (a Frenchman might say) of the *savoir vivre*. It is to be accepted, not in a spirit of restlessness and impatience, still less in the mere happy-go-lucky mood of a Mr. Micawber, but rather as a part of every earnest man's destiny, and in the full confidence that when it is so accepted and so used by a man working in the right way and in a corresponding temper of mind, the opportunity will come, the tide will rise, which "taken at the flood" (as Shakespeare says) "leads on to fortune." And so the immortal dramatist, he who was "not of an age, but for all time," is found to be in perfect accord with that possibly very far inferior authority unknown, who devised and popularised the science of "getting on" in life in the very epigrammatic phrase with which this little address began.

There need be no hesitation, then, in recommending to you, as young graduates entering on a medical life and medical responsibilities, that you should try, above all things, to "know how to wait." That is the very plain and obvious condition, the first step towards ultimate and honourable success in medicine as well as in every other high pursuit. The great statesman, for example, is he who can "take occasion by the hand, to make the bounds of freedom wider yet"; but he must be content to wait for the occasion. The greatest general or admiral at the head of the strongest army or fleet will be the most careful to see that success is not marred by an inopportune moment for an engagement. Why, then, should you, with all the world before you, and all your lifetime to work in, not "know how to wait"? Why risk all that should be most valuable in your life in one ugly rush—character, experience, efficiency in the end—because, owing to faults of temper, or even the laudable desire to "get on," or the apparent and immediate need thereof, you feel tempted to satisfy all your ambitions at once? "Waiting"—in the sense of the proverb—is not idleness, and in our profession of all others it has no need to be an unprofitable or degrading occupation. There is plenty to do for all of us, if we can only accept our just position and act in a subordinate part with frankness and sincerity. It is even a duty of the first order to keep ourselves, body and mind, in a state of preparation for higher duties; and therefore no one can for a moment think of "waiting" in the sense of a folding of the hands or of what is called across the Atlantic "loafing around." No; he who "knows how to wait" will strive to keep himself always ready to use favourably the occasion when it comes. He will instinctively beware of letting his faculties go to rust; and you, graduates, will naturally seek such occupation as will conform to the large and valuable discipline which you have already undergone. But you will, nevertheless, "know how to wait"; and sooner or later the favourable occasion, or occasions, will come. And then, just because you have so waited and so kept yourselves in readiness for them, you will reap your reward.

There is nothing very profound in all this, you will say. No; but still it requires to be thought about seriously and often. Many a promising career has been blasted, many a life practically thrown away; still worse, many an honourable beginning converted to quackery and baseness by not knowing or not believing that all will come right to him who knows how to wait. The temptations of a medical career are not small—it may even be said that to ill-regulated or over-ambitious minds not guided by principle, and easily swayed by self-interest, they are apt to be overwhelming. Let me advert very briefly to only two out of the many.

1. There is the making haste to be rich—not, perhaps, necessarily a fault (much less a crime) in itself, but certainly an unbecoming attitude of mind in an early medical career, and one which is not easily reconciled with the principles of your higher and nobler vocation. "They that will to be rich," says an old and venerable book, "fall into temptation and a snare, and into many foolish and hurtful lusts which drown men in destruction and perdition." It can hardly be disputed that the temptation and snare here referred to receive many illustrations in connexion with the profession of the healing art. Nor is it at all an exaggeration to say that the making of money, if advanced to the rank of a first principle and practised without any scruple or any restraint of honourable tradition, is by far the easiest part of success in the art. The vast fortunes made by the most glaring quackeries, the immense sums spent (it is to be presumed profitably) in the advertisement of remedies which are either worthless or set forth in terms that can only be described as evidently mendacious, are the standing proof that the art of medicine, if pursued as a mere trade, is at once the easiest and the worst, or the most contemptible, of all possible trades. It may, therefore, nay, will often, occur to you in your early career that the restraints upon your freedom of action arising out of the necessary and honourable tradition of centuries, and out of the almost unspoken influence of all that

Digitized by Google

you have been taught in this University, are somewhat in the way of your success, if the "tide which taken at the flood leads on to fortune" is to be merely a tide of fees. I know not if it is an absolutely true story, but it is one which might be true, and almost looks like the truth—that of the bone-setter in Paris, who, on account of some questionable transactions, was visited by the police as practising irregularly without a diploma. The story goes that a perfectly regular diploma was immediately produced; but that the supposed culprit earnestly requested the police agent not to betray him, and explained that he had carefully concealed and deliberately suppressed his diploma, "because" said he, "I once practised on the strength of it and was starving; and now, by behaving like a charlatan, and freely advertising as such, I am already a rich man." The moral of the story is that in the making of money, as in other things, you must "know how to wait." The money will come, unless you are very unlucky, with the gradual increase of reputation and in the faithful, quiet, honourable discharge of higher duties; but to make it a first consideration is almost the sure road to a fatal lowering of tone, to the alienation of your more honourable brethren, and in the end to "destruction and perdition" in a medico-ethical, if not also in the apostolic, sense. In the course of a pleasant excursion not long ago with a number of medical brethren, most if not all of them old pupils of mine, and as good fellows as I can desire my old pupils to be, one of the best and not least successful said to me jokingly, "You never taught us how to make money." I at once admitted the truth of the remark, but it was because in my opinion that part of a medical education may, nay, ought, to be severely left to itself. The money-getting side of your art is very easily, perhaps too easily, learned by those who desire it above all things; but it is not to be looked on as the end, much less the beginning, of your professional efforts. This medico-ethical disability (if such it be) is not one that attaches to our calling exclusively, or even especially. It is true that we have to live by our profession; but at the same time we are bound, as in all high and noble callings, by a much higher law—we are bound in every instance and at every stage of our career so to live that the higher is not sacrificed to the lower. It is not too much to say that every man worth his salt in the medical profession makes up his mind from the first, and advisedly, to do far more for nothing, or for the love of it, than he can ever do for fees. One cannot but regret that it should be needful to place this high doctrine thus clearly and definitely before young and generous minds which are not, as a rule, given over to the opposite view. But the sheer necessities of your early struggles in some cases, and in all cases the hardening influence of a kind of trades unionism that is now being at many points insidiously introduced into professional life, has a tendency to displace its purer and nobler traditions, and to subvert the teaching of that grand old Hippocratic oath, which in a modified shape is still the substance of the declaration that each one of you has adopted to-day as the rule of your life. I will not go into details, because time will not permit. I will rather take an illustration from another calling, which lies ready to hand. In the current number of the *Quarterly Review* there is an article under the title "On Commencing Author," in which you may read as follows: "There are numerous motives operating upon the true man of letters ..... urging him to exercise his vocation, and to exercise it to the very best of his power without being paid for it at all. We do not say that he will not ask for his cheque, or thankfully accept it, but we do say that the motive which prompted him to write, if he is likely to be worth his salt in literature, is a motive with which the cheque had nothing whatever to do." The last word that can be said in this place, on this branch of the subject, is that you should love your profession as such—love it so well and with such a whole heart that you cannot think of it as a mere trade, under whatever apparent compulsion of necessity; and to do this, which in the end will be your true advantage and benefit, even (in most cases) from the pecuniary point of view, you must above all "know how to wait."

2. The second great temptation which tends to make shipwreck of a medical career, especially in its earlier stages, is an uneasy personal vanity or egotism which makes itself, as it were, the centre of the medical universe and is never done inquiring, "Why am I not as well off as A, or B, or C, who may have been more lucky, but is certainly not better or abler than other people"—or than the complainer, to wit? It is very easy to have this feeling within limits, and perhaps impossible to avoid it altogether; but it is also very easy so to cultivate and coddle it under one or another specious disguise that it becomes a perfect passion for demeaning others, a perpetual cover or cloak for malice, hatred, envy, and all uncharitableness. I hope you will most of you avoid yielding to a weakness which is often that of the strongest and most active minds, and which will often claim to be even a virtue in respect of its bold nonconformity or want of respect for persons, in denouncing what it pleases to hold as abuses. The only criticism, however, I am concerned at present to pass upon such persons is that they are usually glaring examples of men who do not "know how to wait," and who therefore allow their talents, their time, and all that should be most valuable to them, to be squandered in personal and for the most part petty disputes and differences. The result is, that instead of everything coming to them *à point*, as in the proverb, they find themselves from first to last handicapped in the race of life by personal animosities and antagonisms, many of which are not shared in even by the persons, of more quiet and even temper, whose peace of mind it has been intended to disturb. I do not say that it may not occur to any one of you to have to take a part, as matter of duty, in controversy; but as a rule controversy, and especially personal controversy, is to be avoided, and is always particularly to be avoided in the case of young aspirants who, from want of experience if not from their own overweening vanities and conceit, may be too readily brought to mistake very small issues for large ones, and so to nurse, as it were, a vindictive soreness at what they deem to be the neglect of their own high ideals. The broad and large common-sense and the generally peace-loving disposition of the medical profession usually discounts the pretensions of such erratic and quarrelsome members of it, and relegates them sooner or later to the category of men who stand in the way of its normal business, because they have never learned "how to wait."

You will see, I trust, from these examples of the snares and possible pitfalls that beset the path of the young graduate waiting for employment and reward, that the temper and spirit in which that *waiting game* (as I have called it) is to be played may have a very large and important influence on your future happiness and success. If the game of life is not a mere haphazard, if it is at all like (say) a game of chess in its intricacy and its demands on your skill, you will not succeed in it in such a way as to be satisfactory to your friends or yourselves unless you give some attention to the laws of the game; and by these I mean not only those obvious and comparatively well-defined rules the violation of which will involve you immediately in disaster, but those laws also—moral, spiritual, and physical—the study of which, and the acting on which, are absolutely necessary to secure a well-founded and enduring success. A false step in the beginning may have consequences to you which can never be repaired. But (what is perhaps of even greater importance), in medicine more than in most other callings a steady and satisfactory progress depends much more upon *character* than even on the most brilliant talents; and character, though it may easily be lost by a single false step, can only be built up gradually by many acts of personal devotion, and by the application in detail of all that you have learned for the relief of suffering humanity during these years of your probation. Hence it may be said with perfect truth that the more modest *rôle* at the beginning, is often not only the safest, but also the most successful (in the best sense of the word) in the end. The subordinate position, while it enables you greatly to extend your experience, and to keep all your powers and your acquirements well in hand for future use, is often much to be preferred to the more ambitious programme, which by giving you a nominal independence would also place you in a position of comparative isolation, with comparatively slender resources that can be turned to future account. A man who "knows how to wait" will not despise the day of small things; but he will say to himself, Whatever happens, I must above all things be ready: I must, in any case, strive to keep what I have learned and earned in the way of skill and experience; and I can only do this, by steadily persevering in getting more. So that the question of immediate success, whether in the way of emolument or of reputation, is often merged in the larger question, How am I to keep my powers intact for a larger success later—to maintain the discipline of mind and of body, of fingers, and of ears and of eyes, the familiarity with practical methods and processes, which ap-

Digitized by Google

till now has made me what I am, a legally qualified practitioner and graduate?

It is at this point, graduates, that I venture to commend to you—not for the first time, as you will find from the other little printed address which I have caused to be handed round among you—the claims of the thesis for the degree of M.D. (such of you as mean to go on by-and-bye to that higher degree) to your careful consideration from the very commencement of your medical career. Under the newest regulations by ordinance, the thesis has ceased to be, what it long was, the only academic test employed in respect of the higher degree; but it remains, and probably will remain, the chief test for honours or distinctions under the new system as under the old. But however it may be in this respect worthy of your early attention, there can be no doubt, I think, that the gradual maturing of the faculties towards a well-considered and, if possible, original thesis on a subject absolutely of your own selection forms an admirable way of keeping your faculties in good repair, of proving your powers to yourselves, and in the end of making them apparent to others without even the faintest surmise of self-advertisement in a bad sense; for the thesis that bears any trace of such a destination is pretty sure to be rejected. So highly do I (and this, I think, is true also for all of us in the medical faculty)—so highly do we all appreciate the value alike to you and to your Alma Mater of a thoroughly good thesis that we heartily wish it were within the power of the University to offer, as has long been the case in Edinburgh, a certain number of gold medals as the reward of very high distinction in this respect. I may add to the expression of this wish (not now for the first time), that without any certain knowledge I am also not altogether without a hope that through the goodwill of some benefactor proceeding upon a recognition of the desire in question it may ere long be accomplished.

I have hitherto considered the French proverb or epigram with which we began from the point of view which was probably that of its unknown author—viz., as referring to worldly success only, or chiefly; a high kind of worldly success, it is true, and such as we, your professors, wish for all of you in your art; certainly not such a success as forms in and by itself a degradation of the art of healing But I should like before I close to lift the argument for a moment into a yet higher region, and to show you, if possible, that there is a very grand and noble interpretation of the proverb, a spiritual sense of it, in which the "waiting game" may be played with absolute security and with a success, in the highest sense of the word, that none of the "chances or changes of this mortal life" can ever diminish or take away. In one of his most intricate and, I will add, difficult arguments in the Epistle to the Romans (Chapter viii., v. 28) St. Paul has formulated for us a proposition which, although I do not much approve in general of texts as detached from their surroundings, I will take the liberty on this occasion of so detaching; inasmuch as while the context is of the nature of an argument, and one which has led to much controversy, the few words I refer to are really of the nature, not of argument, but of deep spiritual experience, and have a very curious parallelism, so to speak, with the wording, not to say also the meaning, of the French proverb. "We *know*," says St. Paul (not as admitting any doubt of it at all) "that all things work together for good to them that love God." Listen again to the Frenchman: "*Tout vient à point à qui sait attendre.*" Is there any real relation or connexion between these two expressions? I think there is; and if you will bear with me still for a few minutes I will endeavour to show you that the relation is not only real, but that it goes to the very root of the whole matter.

Huxley, in one of his early discourses upon the laws of Nature, has a superb—I would say a noble, even a sublime—image which ought, in my opinion, to have gone one step further, but which, even as he has it, might have saved him from the remarks of some who have confounded his agnosticism with irreverence. He represents man as playing for his life at a game of what we ignorantly call hazard, against a beneficent and pitying angel, who as a matter of duty will always oblige him inexorably to keep the laws of the game whether he loses or wins; but who, so far from being vindictive or adverse in feeling to man in this trial of his powers, "would as soon lose as win." Now, this is Huxley's way of saying, in what he regards as scientific (though at the same time highly imaginative) language, what our Frenchman has said in the proverb; and it is also, I think, a reflection in some degree (though, of course, without the theistic and emotional element) of the burning words of St. Paul. The point which is common to all three is the idea that human life, its successes and its failures, are in some way or other under the influence of *laws;* and even Huxley, who was no materialist, would assuredly have admitted (though he does not say so) that these laws of our being extend over the mental, moral, and spiritual region as much as over the material. Play the game, he says, according to the rules; for if you do not, ignorance of them will not protect you, but if you do you *may* win, and, in any case, will have done your best. Be sure, says the Frenchman, that if you can only *wait* and be ready, the occasion will come, and with it all things will come to a point for you. Love God, says St. Paul, and all things are yours; for "all things work together for good" to such as love God and conform to His sovereign will. Of course, there is an element here that is not found directly in the other two. It is what we may call the definitively Christian or religious element. The French proverb here is carried up to its highest terms in the form of a great and far-reaching spiritual experience.

But in another and, perhaps, an even more remarkable phrase used by St. Paul elsewhere the sublime idea here set forth is carried on a stage further. Of himself and Apollos he says, in speaking of the foundation and planting of the Corinthian Church (1 Cor. iii., 9), "We are God's fellow-workers; ye are God's husbandry, ye are God's building." This working together of all things for good, therefore, admits of active as well as passive coöperation with God, and those that work on these lines in the love of God are συνεργοὶ τοῦ θεοῦ—labourers together with God (as the Authorised Version has it); God's fellow-workers, more literally and more strikingly, in the Revised Version. Here, one can see at once, is the implied condition of the *synergy*, the working together for good, that is pointed to in Romans. In doing God's work, doing it consciously and along with Him, we cannot fail to have Him with us. Thus it is that "all things work together for good to them that love God" and are willing to coöperate with Him in His work. Success in life, as this view of the matter puts it, depends on what you mean to do and how you mean to do it. If your only objects are money, reputation, a crowd of patients, and large fees you may very easily fail; nay, you will certainly fail in some degree, for the desire in these cases increases usually beyond the means of its satisfaction. But if you desire, humbly and reverently, to work the work of God, and be a "fellow-worker" with Him, in what profession can you accomplish this object more consciously, more surely, or more inevitably than in ours?

Natura non nisi parendo vincitur. In that saying of the great Chancellor, Francis Bacon, is contained the whole secret of medical as of all other real success. Whether it is the healing of a broken bone, or of a wound, or of a fever, it comes round again to that. By obeying the laws of nature by working consciously along with them, by adapting our efforts to their conditions, we, too, become "fellow-workers with God." In the material as in the spiritual world it is the same law which governs the whole. God is the great worker—the great Healer. It is through knowing His laws, and acting on them and through them, that we can best, or indeed alone, coöperate with Him. And in so working with God, even if we have to wait for it, success is assured. "*Tout vient à point à qui sait attendre.*" Only, for success in the highest, in the only real sense, it is necessary to "love God" as well as to know His laws. Then, indeed, we shall find that "all things work together for good," and the "waiting game"—even if it comes to that—is assured of success.

Few things in the personal history of great men are more pathetic and at the same time more encouraging from this point of view than what we have come to know of the blindness of John Milton. It came upon him, not suddenly it is true but completely, in his forty-fourth year. "What a fate!" writes Professor Masson, in detailing all the circumstances with his usual pious care and unwearied diligence. "All his intentions, all his projects, all his hopes of further activity and usefulness, turned into mere gropings through a future of blackness. His secretaryship, to which he had been accustomed, the duties of which he had come to like, how on any terms could he give up that? Then, apart from his secretaryship, the cutting short of his own cherished studies and the fond occupations of his life hitherto, his miscellaneous pursuit of

Digitized by Google

knowledge, his commerce with the books he had gathered about him and with the libraries at hand, his unfinished controversies"—all this and more, it will be admitted, forms a most discouraging picture of calamity and possible ruin in the very middle of a great career. But Milton was one of those men who know how to wait. He tells us so himself in those two admirable sonnets to Cyriac Skinner, in 1655, when the calamity had already been borne for three years. He had a good many more years to wait before he had quite accommodated himself to the new conditions. He had to go into hiding at the Restoration, and then to live in comparative obscurity after he had regained his freedom. Altogether, it was a very poor case, speaking from the point of view of the worldling, for the man who under Cromwell was probably the most powerful as well as most renowned of Englishmen, Cromwell himself excepted, and whose "*Defensio pro populo Anglicano*," with its bitter controversial sequels, were not only in some degree the causes of his blindness, but also of his exultation; as he himself says:—

"Liberty's defence, my noble task,
Of which all Europe talks from side to side."

Yet it is none the less true that for us, and for all time, the real greatness of Milton was, in a very genuine sense, the outcome of his blindness and comparative obscurity, for to these we owe "Paradise Lost" and "Regained," "Samson Agonistes," &c., while the "Defensio" is now only rescued from oblivion by its being the work of one at no time unconscious of his own great powers, but who had assuredly not taken a just measure of them when he wrote in early despair of his great calamity just alluded to:—

"That one talent which is death to hide,
Lodged with me useless"—

and when, in the calm anticipation that his time of activity and usefulness was ended, he brought this wonderful sonnet to a close in the line:—

"They also serve who only stand and wait."

I hope most sincerely, ladies and gentlemen, that none of you will have a trial like that of John Milton. But if it should be so, you will draw some encouragement and some small degree of hope, it may be, from his noble example. At all events, your course is now clear. You are graduates of this ancient University, and, as such, fully entitled to practise the art of healing throughout Her Majesty's dominions. We desire to accord you our heartiest congratulations, and to part with you in sincere good-will and with every disposition to help you in your work. What that work is to be we do not presume any longer to dictate. But whatever it may be, we trust that you will apply yourselves to it in the spirit of Longfellow's noble lines, which form the conclusion to the "Psalm of Life," and with which I, too, will close this address:—

"Let us, then, be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labour and to wait."

AMYLACEOUS DYSPEPSIA.

BY JAMES TAYLOR, M.B., B.CH. R.U.I.

DURING the last few years so much has been written in regard to that complaint which is so common, and which plays so important a part in the life-history of patient and practitioner alike—dyspepsia—that it cannot be said that the subject has not received its due share of attention at the hand of the profession. But, notwithstanding all that has been said on the subject, clinical results show clearly that our knowledge of the pathology of the many varieties of dyspepsia is still very meagre. That the complaint is a difficult one to deal with becomes evident when to the consideration that in a large proportion of dyspeptics no evident anatomical lesions can be detected in the organs to which the maldigestion of the food can be referred, we add the fact that there is such an intimate relationship between the different organs concerned in the processes of digestion that when derangement in an organ takes place it is difficult to say which one is primarily at fault or how far the defaulting organ may influence the others. Amylaceous dyspepsia is a variety of this complaint which until recently seems to have received little attention apart from its inclusion in the consideration of a general condition at the hands of the profession. It is to this form that I would now briefly call attention.

It has been assumed that the pronounced acidity coming on in dyspeptics after meals is caused by an increase in the quantity of hydrochloric acid in the gastric juice. In the majority of cases the burning fluid which regurgitates into the mouth is a mixture of lactic, butyric, and acetic acids arising from the fermentation of the carbo-hydrates and fats. The gases and acids arising from the fermentation of the fats do not constitute an important clinical factor, owing to the comparatively small amount of fat taken as food, and when fermentation of this class of foods takes place it occurs most frequently in connexion with a like process in the carbo-hydrates. Illustration of the process is to be found, in a general sense, in the formation of the lactic acid, which can be readily produced artificially by placing bread with water in a warm chamber. During the process which ensues the sugar of the bread is converted into lactic, butyric, and acetic acids.

To understand what the derangement termed amylaceous dyspepsia is, it is necessary to have clearly before our minds what occurs during the normal digestion of amylaceous substances. In this connexion I may mention that the recent contributions by Dr. Christopher to the subject of indigestion are interesting. He prefers the term "super-digestion" to "indigestion." According to this authority the normal digestive processes are due to fermentations brought about by the unorganised ferments of the alimentary canal. Pathological fermentations are induced by organised ferments and micro-organisms, which exert their peculiar action on the products of normal fermentation. In other words, he defines super-digestion to be the result of pathological fermentations of the products of normal digestion. In salivary digestion the starchy portions of the food are transformed into maltose and dextrine. This change may be represented by a chemical equation:—

$$\underset{\text{Starch.}}{3(C_6H_{10}O_5)n} + nH_2O = \underset{\text{Maltose.}}{nC_{12}H_{22}O_{11}} + \underset{\text{Dextrine.}}{nC_6H_{10}O_5}.$$

This transformation takes place best in a neutral medium. Until recently it was supposed that the action of the ptyalin of the saliva was stopped immediately the food entered the stomach, owing to the hydrochloric acid being formed in sufficient quantity at the commencement of gastric digestion to neutralise the alkaline saliva. Velden has, however, shown that there is no free acid in the stomach before the expiration of from three-quarters of an hour to two hours after the arrival of food in that organ. During the earlier stages of digestion it is almost certain that the hydrochloric acid secreted combines at once with the proteids, and that no free hydrochloric acid appears in the gastric secretion until the proteids have combined with as much hydrochloric acid as they require. It is supposed, therefore, that during this interval the ptyalin is permitted to maintain its action. This hypothesis was confirmed by the observations of Chittenden and Ely, which showed also that saliva neutralised with acid is more active than ordinary alkaline saliva. A portion of the acid secreted by the stomach in the early stage of gastric digestion is thus presumably used in the neutralisation of saliva, and is, in consequence of this action, an aid to ptyalin, which is, *per se*, an active ferment. The resulting products of starchy proteolysis begun in the mouth and carried on in the stomach are therefore the same as those resulting from the action of saliva alone—namely, maltose and dextrine, the action being merely increased. Ultimately the greater part of the dextrine is changed into maltose. No grape sugar is formed. Therefore, in cases of excessive acidity we must look for some other source of the lactic acid, and in order to do this we must consider the action on the cane and grape sugars taken as food. Cane sugar becomes converted into invert sugar (a mixture of lævulose, or fruit sugar, and dextrose, or grape sugar), and grape sugar lends itself readily to the process of lactic acid fermentation. This accounts for the fact that intolerance is shown by many dyspeptics to saccharine substances. The changes in grape sugar are the result of the action of fermentative organisms, and may be represented by a chemical equation:—

$$\underset{\text{Grape sugar.}}{2C_6H_{12}O_6} = \underset{\text{Lactic acid.}}{4C_3H_6O_3}$$

$$\underset{\text{Lactic acid.}}{2C_3H_6O_3} = \underset{\text{Butyric acid.}}{C_4H_8O_2} + 2CO_2 + 2H_2$$

Digitized by Google

The conversion of starch ceases on the appearance of free hydrochloric acid in the gastric secretion, as ptyalin is destroyed by the acids of the gastric juice in full digestion. The digestion of starch is, however, resumed again in the intestine under the influence of the pancreatic and intestinal secretions. The amylopsin of the pancreatic fluid converts starch into maltose, which is further slowly transformed into grape sugar. Cane sugar is an important article of food, and is consumed by us in large quantities daily. It is, however, a crude form of food, and requires to be converted into invert sugar, which, as has already been stated, is a mixture of lævulose and dextrose. This transformation is brought about under the influence of the inversive ferment of the intestinal secretion, and may be represented by an equation:—

$$\underset{\text{Cane sugar.}}{C_{12}H_{22}O_{11}} + 2H_2O = \underset{\text{Dextrose.}}{C_{12}H_{24}O_{12}} + \underset{\text{Lævulose.}}{C_{12}H_{24}O_{12}}$$

Under pathological conditions the grape sugar resulting from the digestive processes in the intestine yields lactic and butyric acids. Or the grape sugar may undergo the alcoholic fermentation, and the resulting alcohol may in its turn undergo the acetous fermentation, forming acetic acid. This super-digestion is brought about under the influence of fermentative organisms, which are more constant in the intestine than in the stomach. Super-digestion of carbohydrates occurs, as already stated, in those disordered conditions in which excessive fermentative processes are occurring. The clinical features present in these cases are: pain of a sickening, weakening character, coming on about three or four hours after food, referable to the abdomen, but not as a rule localised. Relief is usually experienced on taking food. There are paroxysms of marked severity at night, loss of weight, abdominal distension and tympanites, furred tongue, and constipation.

From what has been said it may be presumed that in all probability the distress after eating experienced by many dyspeptics is not necessarily due to a deficiency of pepsine (some authorities deny that deficiency of pepsine does occur), but rather to an accumulation of gases and acids produced by the fermentation of the food in the stomach and intestine. If the discomfort does not commence until three or four hours after the ingestion of food we may take it for granted that the fermentation is mainly or entirely intestinal. The view that pathological intestinal fermentations take place for the most part in the products of normal digestion is supported by the fact that intestinal disturbance is induced in the majority of these cases by a vegetable diet. This is not to be wondered at when we consider that fully two-thirds of the food of mankind consists of starch, and that the greater portion of the starchy food reaches the intestine unchanged. In some rare cases fermentation of the normal products of salivary digestion takes place in the stomach, for, in the absence of hydrochloric acid, gastric digestion would be attended normally by the formation of fermentation acids and gases, giving rise to pain and discomfort shortly after the ingestion of food. Lactic acid formation in any appreciable quantity is an evidence of the deficiency of the normal acid of the gastric juice. Under these circumstances the administration of hydrochloric acid might be beneficial.

With regard to the treatment of those cases in which excessive fermentations of the products of starchy proteolysis are occurring in the small intestine, it is obvious that to eliminate carbohydrates from the food and to strictly limit the diet of the patient to purely albuminous substances for about a fortnight would bring relief. In doing so, however, we overlook the importance of starch as an article of diet. In addition, such albuminous diet is irksome and monotonous, and the patient loses weight. On the whole, it would be better to lessen the quantity of amylaceous substances than to forbid the use of them altogether. Intestinal antiseptics given with the idea of destroying the micro-organisms concerned or by lessening their power to produce fermentative changes have been found useless in my hands. The principal seat of trouble being in the intestine, and the use of antiseptics being attended with no advantage, we seek for some method of digesting amylaceous substances in the stomach, so that they may be absorbed by that organ and little or none reach the intestine. Our object can only be carried out effectually by means of a powerful diastasic ferment. The proper choice of a diastase is important. Many malt extracts contain much saccharine matter. This is mostly in the form of grape sugar, which, when eaten in large quantities, tends to undergo fermentation in the stomach, even when the secretion of hydrochloric acid is normal and commences in the usual course. Moreover, the normal processes of digestion are naturally slow, in order that the products of the digested food may present themselves slowly for absorption and so become available only as they are required for the support of the slow nutritive processes. If a quantity of predigested food be ingested there arises the risk that it will be rapidly absorbed into the blood and be rapidly excreted without having imparted any of its nutritive qualities to the tissues. In addition, too rapid absorption into the blood not only disturbs the equilibrium of that fluid, but also produces disturbance in the liver functions. This in all probability explains the reason of the biliousness produced in some individuals by the use of malt extracts. Naturally, we eat starch in preference to grape sugar, the starch being slowly converted into sugar in quantities with which the healthy organs can deal. None of these objections hold good in the case of the preparation called "taka-diastase," introduced by a Japanese chemist, and of all the preparations I have used to give relief in amylaceous dyspepsia I find none which gives such good results as those obtained by its use. Its action has been at once prompt and efficacious in the cases in which I have prescribed it, I being one of the number. Prior to the time at which it came under my notice I had used the various preparations of malt extract, but, whatever their value as nutrients and as vehicles for the administration of other preparations, I have found little gain attend their use in amylaceous indigestion. Our object is to convert the starchy matters of the food into maltose in the stomach prior to the onset of peptic digestion, and we have in this digestive agent a substance capable of fulfilling that object, for not only is its activity great, but it is said to produce its characteristic effects on starch immediately it comes in contact with the last-mentioned at the normal temperature of the body. The dose is 2½ grs. in tablet or powder, to be given at the commencement of a meal. It would be useless to speak favourably of the action of any artificial digestive ferment without at the same time emphasising the necessity for proper dieting. In these cases of amylaceous dyspepsia the starchy elements of the food should be properly cooked. Diastase cannot act on the starch granule unless the cellulose investment has been ruptured by the process of cooking, during which process the starch, under the influence of heat and moisture, swells up into a jelly-like mass. Without this previous change starch is but slowly acted on by diastase. Proper mastication of the food is essential, so that the juices of the mouth may be thoroughly incorporated with the starchy elements of the food and salivary digestion be well begun before the food enters the stomach. Excessive use of saccharine substances should be avoided, for not only are they liable to undergo lactic acid fermentation, but they hamper the action of the ptyalin. The patient should be warned against the custom of taking quantities of fluid with the meal, on account of the tendency then present to wash the food quickly down instead of masticating it properly and mixing it thoroughly with the saliva. Fluids used at meal-times should, therefore, not be sipped with the meal, the rule being to eat first and drink afterwards. Tea has an inhibitory effect on salivary digestion owing to the presence of tannic acid in the leaf. It should be made weak and used sparingly, and should, like other fluids, be taken after meals. A small quantity of bicarbonate of soda added to the tea in the teapot is said to neutralise the effect of the tannic acid. In conclusion, I would remark that in no case did I find taka-diastase fail in giving good results in amylaceous dyspepsia, and many of these results were obtained after a fair trial had been given to many diastase and other preparations.

Belfast.

THE death is announced of Dr. William Jepson at the ripe age of eighty-five years, formerly a well-known and esteemed medical practitioner in the Salford division of Manchester, whence he retired to Saltash, in Cornwall, in 1881. *Inter alia*, Dr. Jepson was an accomplished botanist and one of a small band who devoted leisure hours to collecting and arranging the wild plants, ferns, and mosses which were more abundant then in the moors and country around Manchester than they are at present. This pursuit, coupled with practical studies in chemistry, was continued at Saltash until failing eyesight and advancing years compelled a cessation. Dr. Jepson was at one time lecturer on botany at the Chatham street School of Medicine, Manchester.

THE SURGICAL TREATMENT OF ANKYLOSIS OF THE TEMPORO-MAXILLARY ARTICULATION.

BY A. T. CABOT, A.M., M.D.,
SURGEON TO THE MASSACHUSETTS GENERAL HOSPITAL.

THE subject of ankylosis of the temporo-maxillary joint has received considerable attention from surgical writers, and many cases of operation for this condition have been reported. Like most procedures in surgery, these operations have a post-antiseptic history very different from that which they showed in pre-antiseptic days. Formerly, if the bone was divided and a false joint made, it was a not uncommon experience to have so considerable an inflammatory swelling and so much pain that the bones were fixed and held in apposition by the spasmodically contracted muscles, and when, finally the parts were so far advanced towards healing as to permit of forcible motion being attempted, it was usually found that the ends of the bones were so fastened together that in spite of all endeavour the ankylosis returned and the case was no better than before. In attempting to obviate this difficulty extensive resections of the ascending ramus were undertaken in some cases, with the object of removing so much bone that the severed parts could not afterwards come together and unite. Of the operations devised upon this plan perhaps the most successful has been that of Esmarch, which consists in the removal of a wedge-shaped piece from the junction of the ramus and body of the maxilla through an incision just behind the angle of the jaw. In 1872, when surgery, stimulated by antiseptic teachings and results, was pushing forward along all lines, Bottini reported a case in which a good, permanent result was obtained by division of the neck of the jaw close to the articulation, and it was soon found that under aseptic conditions this method could be relied on to give a good false joint. Since that time these two plans, with occasional modifications by other operators,[1] have been rivals in the treatment of these deformities.

In considering these operations we must carefully distinguish between those cases in which the ankylosis is largely due to extensive cicatricial formations in the soft parts, as a result of noma, lupoid inflammation, or burn, and those in which there is a true bony ankylosis of the temporo-maxillary joint without involvement of the soft parts. When the jaws are bound by cicatricial contraction the section of the bone must be in front of the cicatrix, or at least must be so placed that the portion of the bone that is freed by the operation is no longer held by cicatricial bands. Necessarily, therefore, the division must usually be close to the body of the jaw, and for these cases Esmarch's operation is admirably adapted and obtains the best mechanical condition of the jaw possible under the circumstances. In the second class of cases, however, of true bony ankylosis it is plain that, other things being equal, the nearer the new joint is to the site of the old one the more nearly it conforms to the conditions on which the muscles were designed to act, and on which, *a priori*, they act best. In comparing, therefore, an operation which makes the section of the bone close to the old articulation with one which makes it at or near the angle of the jaw, we have to consider the former as the better operation, unless it has disadvantages either of danger, untrustworthiness, or unsightliness which more than counterbalance its mechanical advantages. My experience of the high section of the bone leads me to think it has none of these disadvantages, for in the seven cases in which I have operated in this way the mechanical result has been uniformly good, showing the trustworthiness of the procedure, and in none of them has the scar been unsightly. In all but one case it has been so slight as to readily escape observation at the end of a year. It is so placed that the hair can often be drawn forward over it and conceal it altogether. Paralysis of the orbicularis palpebrarum muscle was troublesome in two of the early cases, but finally disappeared. By keeping the incision close up to the zygoma this can be avoided.

I have met with no especial element of danger in these operations except that which is common to any operation upon an ankylosed jaw—namely, the danger of asphyxia under anæsthesia. In one case the breathing was stopped by the falling of the tongue into the throat, and a quick tracheotomy was performed. Recognising this danger, I have always had the tracheotomy instruments laid out during these operations, and this was the only case in which I had to use them. It is true that a case is reported in which the carotid artery was wounded, but this would have been avoided had the section of the bone been carried out inside of the periosteum in the manner I shall presently describe. My operation has been in the main after the manner of Bottini. It has been as follows. In the first place, to discover on which side the ankylosis exists is not always easy. Cases have been reported in which the sound side was operated on by mistake. To determine this point the history should be investigated, and often it will be found that the original osteo-periostitis which led to the ankylosis was distinctly limited to one articulation. The history is, however, often doubtful on this point, and a decision must be reached by an examination of the jaw itself. If the fingers are pressed in on the teeth upon each side, and at the same time the patient makes vigorous attempts at mastication, a springing of the bone on the free side will be noticed, in quite distinct contrast to the fixity on the ankylosed side. Furthermore, as there is usually a loss of cartilage and even of bone in the process which destroys the joint, the jaw naturally falls over to that side, and this lateral displacement may be readily made out by noting the relation of the middle lines of the two jaws as shown by the incisor teeth or otherwise. After a study of these several points a mistake must be exceedingly rare. In my first two cases I made the incision vertically over the neck of the jaw, but later I adopted Bottini's incision along the lower edge of the zygoma, with a vertical cut added if more room was needed. The vertical incision should not extend far down in front of the ear lest the facial nerve suffer injury, but it may run up over the zygoma. The incision is carried at once down to the bone, which is cleared by a periosteum elevator. The division is then made with a chisel, which cuts out a wedge across the whole width of the bone which represents the neck of the jaw, even when this is a mass involving both the condyloid and coronoid processes. With care this division can be kept within the limits of the periosteum, and all danger of injury of the carotid artery is thereby avoided. To ensure safety a curved retractor may be carried under the posterior edge of the bone during the use of the chisel, thus wholly obviating any danger of injury to the vessels lying there. In none of my cases has the internal maxillary artery even been injured. When the bone is completely divided the final separation may be accomplished by pushing a wedge-shaped screw gag into the cleft in the bone and so forcing it apart. The ends of the bone are then readily rounded off with rongeur forceps. The hæmorrhage is trifling and the wound may be tightly closed. A cork should be kept between the teeth on the injured side for the first week or fortnight while the healing is going on, but may be taken out as often as is desired for passive motion after the first three or four days. The following is a brief summary of the seven cases on which I have operated.

CASE 1.—A girl, aged thirteen years, suffered from ankylosis of the left temporo-maxillary joint for ten years the result of scarlet fever. She was operated upon in August, 1887, the neck of the condyle being chiseled through just below the point where it became welded into the temporal bone. This was done through a vertical incision about one inch in length. Slight loss of power over the eyelid supervened, but this disappeared after a few months. The patient was seen on Jan. 19th, 1895, eight years after the operation. At that time the scar of the incision was barely visible. She noticed that to tightly close the left eye required more effort than in the case of the other, but the ordinary movements of the eyelid were perfect. The left side of the jaw was somewhat undeveloped as compared with the other. The mouth opened three-fourths of an inch,

[1] Dr. J. E. Mears has reported an operation through the mouth in which he saws the ramus through on a level with the last molar tooth, and after separating the attachment of the temporal muscle he seizes the bone with lion forceps and forcibly twists it out. If it yields at the neck the condyle may be chiseled out and left. This method would not seem to be applicable for those cases in which both condyloid and coronoid processes are welded firmly to the bones of the skull, a condition not always discoverable before operation. The slight scar of the external operation makes it of less importance to attack the bone at a disadvantage within the mouth; and in the cases to which Dr. Mears's operation is applicable it removes more bone than is necessary, and has in that way a mechanical disadvantage. The results that Dr. Mears has figured are certainly very good.

Digitized by Google

and there had been no change in this since just after the operation. Lateral motion was considerable, one-quarter of an inch or more, and the grinding power was good.

CASE 2.—The patient, a girl aged seventeen years, had ankylosis of the left temporo-maxillary articulation of thirteen years' standing, which followed mastoid disease caused by scarlet fever. She was operated on in July, 1888. The operation was begun with a vertical incision, but as it was found that the coronoid process was also involved in the mass of bone welding the maxilla to the temporal bone a cross incision was made along the lower edge of the zygoma. This patient was examined on Jan. 9th, 1895, eight years after the operation. The scar of the operation was not very noticeable, and she said that its appearance had caused her no annoyance. When her mouth was widely open the gums were $\frac{1}{2}$ in. apart, and with her plates of teeth in place she could open her mouth half an inch. The mastication was vigorous and she had capital grinding power. The eyelid had good motion.

CASE 3.—A woman, thirty years of age, fell when three years old, striking her chin, and this was soon followed by ankylosis of the left temporo-maxillary joint. Forcible attempts to separate the jaw with wedges accomplished a bending of the body of the lower jaw, so that while the molars and even the gums in the back part of the mouth were in close apposition the incisors were about one-half a centimetre apart. An operation was performed in April, 1889, in the manner followed in Case 2, and here, too, the welding of the jaws to the temporal bone was by a thick irregular mass of bone. Some temporary paralysis of the eyelid followed the operation. This patient was seen on Jan. 14th, 1895. The motions of the jaw were well preserved and the grinding power was excellent. When the mouth was open the aperture between the teeth measured between three-quarters of an inch and an inch. The scar of the operation was practically invisible, it being difficult to determine, except by close inspection, which was the side of the operation. While the motions of the eyelid were perfectly preserved there was a perceptible difference between the action of that side of the face and the other. This was mainly noticed when laughing, and consisted in an excessive action of the muscles around the eye on the affected side rather than in any lack of power in them. This was so slight as not to be annoying.

CASE 4.—A woman, aged thirty-two years, received a blow upon the jaw when six years of age. This was soon followed by ankylosis of the right side of the jaw. An operation was performed on Dec. 13th, 1889. The incision was made just beneath, and parallel to, the zygoma and was crossed by a short vertical incision through the skin alone. The condyloid and coronoid processes were both welded to the skull by an irregular mass of bone. This was chiseled through. She left the hospital well on the thirteenth day after the operation. The patient was seen in Dec., 1894. At that time the scar of the operation was barely visible. The motions of the jaw were good. The mouth opened a little over an inch and there was good grinding power with lateral motion of a quarter of an inch. The motions of the eyelid were perfect.

CASE 5.—A woman, aged twenty-six years, suffered from anklyosis of the temporo-maxillary joint, which had followed a blow on the chin in infancy. An operation was performed on July 15th, 1890. The first incision was beneath and parallel to the zygoma, with a short cross incision through the skin. In the midst of the operation the patient became asphyxiated owing to the dropping of the tongue back into the throat. An immediate tracheotomy was performed and the chiseling of the jaw was then finished. The wound suppurated, owing, no doubt, to some contamination of it after the tracheotomy. Still, the recovery was not seriously interfered with and the patient left the hospital twenty-three days after the operation. This patient was seen on Jan. 7th, 1895, four and a half years after the operation, when the possible separation between the incisors was an inch. Lateral motion was one-quarter of an inch. The grinding motion was good, but the grinding was interfered with by the irregular arrangement of the molar teeth, which did not properly correspond in the two jaws. The scar was slightly depressed, but not unsightly. Movements of the eyelid were not in any way interfered with.

CASE 6.—A boy, aged eight years, had scarlet fever when six years old. Otitis followed, and rapidly progressing ankylosis of the jaw occurred. When seen the jaw was fixed by bony ankylosis, with the teeth immovably in apposition. He was operated upon on Jan. 15th, 1890. A short incision was required as the condyloid process alone was fixed to the temporal bone, and the section and removal of the neck of the jaw was easily performed. The wound healed by first intention, and he left the hospital in nine days. He was seen two years later with perfect control of all the motions of a mouth which opened as widely as in any boy of his age. He had perfect grinding power.

CASE 7.—A woman, thirty-seven years of age, when she was aged seven years, received a blow on the right cheek, followed by much pain about the ear, with gradual closure of the jaws, so that at sixteen years of age they were tightly approximated and fixed. Forcible efforts with wedges accomplished a sufficient separation to allow of the food being pushed between them. She was operated upon on July 19th, 1891. The incision was made parallel to, and close under, the zygoma. As in all but two of my seven cases, the upper end of the ramus was welded to the skull by a large irregular mass of bone which was chiseled through. The recovery from operation was uneventful. This patient was seen on Jan. 8th, 1895. She had had all the lower teeth but one molar drawn, and had not yet had a plate made. There was a distinct downward bend in the body of the lower jaw as a result of the long-continued wedging which had preceded operation. As a consequence of this, the anterior gums did not closely approach the upper teeth, being held apart by the last remaining lower molar. The jaws could be separated an inch, and there was fairly good grinding motion, as appreciated by the rubbing to and fro of the solitary lower molar against the upper range of teeth. The scar was not conspicuous and the motions of the eyelid were good, though she said that when she was tired or nervous she was somewhat troubled by twitching of that eye.

The first two of these cases were published in the Transactions of the American Surgical Association (vol. vii.), the others have never been reported. The restoration of motion in all of these cases was thoroughly satisfactory, and has been maintained now for a sufficient number of years in each case to warrant the belief that it is permanent. It is particularly worthy of note that the grinding power was recovered in every case. In Cases 1 and 6 the division was through the neck of the condyle, so that all of the masticatory muscles retained their proper relations, except the external pterygoid, which was separated from its attachment. In the other cases the coronoid process was involved in the ankylosis, so that in them the attachment of the temporal muscle was also lost. The masseter and internal pterygoid muscles were in no way interfered with, and gave ample support and power to that side of the jaw.

A review of the literature of the subject has yielded reports of sixty-two operations upon cases of bony ankylosis of the temporo-maxillary articulation, and the five hitherto unreported cases of the writer bring this number up to sixty-seven. Of these, forty-seven were done by Bottini's method and twenty were done by other methods involving a section of the jaw through the ramus at some point nearer the angle. These figures would seem to show a preponderance of surgical opinion in favour of the operation close to the zygoma. A careful comparison of the functional results by the various operations is impossible on account of the incompleteness of many of the reports in this regard. As far as could be judged, however, the method of Bottini furnished better power of motion than any of the operations near the angle. This search into the experience of others has thus confirmed the opinion which the writer formed from the study of the mechanical principles involved and of the final permanent results in his own cases, and has led him to consider the operation devised by Bottini to be the best one known, up to the present time, for the relief of this most distressing deformity.

The following references to the literature of the subject, which are all that a rather thorough search has yielded, may be of service to future investigators.

POINTS OF POSSIBLE MEDICO-LEGAL INTEREST IN CERTAIN CASES OF DISSEMINATED MILIARY TUBERCULOSIS.

BY F. PARKES WEBER, M.D. CANTAB,
PHYSICIAN TO THE GERMAN HOSPITAL.

IN disseminated miliary tuberculosis there may be doubts as to the medico-legal aspect of the case during life, the doubts being afterwards completely cleared up by a post-mortem examination; but in other cases points of medico-legal interest may first attract attention at the time of the necropsy. Instances of the first class are sometimes afforded by tuberculous meningitis supervening in adults. The following is an example.

CASE 1.—A German, aged nineteen years, was brought to the German Hospital suffering from fever and delirium. He could answer no questions and there was no history obtainable. The physical signs were not quite the same over both pulmonary apices, and this caused tuberculous meningitis to be suspected. There was, however, much albuminuria—a condition not usually associated with tuberculous meningitis—and neither ophthalmoscopic examination nor special nervous symptoms helped us. It was therefore possible that the patient had taken some poison acting on the kidneys and nervous system. He died some days later, and the post-mortem examination cleared up the diagnosis. Tuberculous meningitis was found, together with old and recent tubercle in the lungs, and miliary tuberculosis of the mucous membrane of the glottis. The kidney affection was parenchymatous, probably due to the bacillary toxins which had to be excreted.

Cases of tuberculous meningitis in adults are probably not rare in which, if there were absence of past history, a temporary suspicion of poison or foul play might be entertained. In the foregoing case the absence of past history and the presence of much albumin in the urine led to doubt in the diagnosis. In such cases the doubtful points are cleared up by the post-mortem examination. It is, however, the second class of cases to which I wish to draw attention—cases of disseminated miliary tubercle in which pathological questions of medico-legal interest occur at the time of the necropsy. Their importance arises from the fact that a blow or injury to quiescent tuberculous nodules in any exposed region of the body may give rise to acute miliary tuberculosis of the lungs, thus bringing about death in persons previously in apparent health. The following is a typical example.

CASE 2.—A well-built man, a German, aged thirty-three years, was admitted under my care at the German Hospital on April 5th, 1897. He had fever (temperature 103·6° F.), vomiting, great dyspnœa and cyanosis, intense dryness of the throat, and scanty expectoration, in which a trace of altered blood pigment was at one time visible. On examining the lungs no definite signs of consolidation could be made out, but a certain amount of fine inspiratory crepitation was heard over both sides, and the case seemed to be one of acute double pneumonia before the outer parts of either lung had become hepatised. The history was that ten days before admission, when on board ship on his way back from the Transvaal, he received a blow on the left testis, which was followed by local and general symptoms. After five days his condition improved somewhat, but two days previously to admission he had a rigor and pains over the whole of the body. Except for some slight improvement soon after admission, due to rest and cessation of the vomiting, his condition underwent but little change. The dyspnœa and orthopnœa increased and the fever remained continuous till he died, practically suffocated, on April 20th, about twenty-five days after receiving the blow on the testicle. In the meantime, owing to the absence of any crisis, and since there were no signs of definite hepatisation of the lungs, we had come to suspect that the pulmonary disease was one of acute miliary tuberculosis. The crepitations were variable; on one occasion distinct inspiratory crepitations could be heard below both clavicles. The sputum was examined for tubercle bacilli with negative results. The urine contained a little albumin. At the necropsy both lungs were found to be engorged with blood and absolutely stuffed with miliary tubercles. There was some fibrosis from earlier disease at both pulmonary apices. The bronchial lymph glands were enlarged, and besides miliary tubercles in the pleuræ there was evidence of older pleurisy, especially over one lung. The left epididymis (i.e., where he had received the blow twenty-five days before his death) contained a softened, caseous nodule, smaller than a small cherry. The cerebral meninges contained no tubercles, nor were tubercles found in any other organs, except a few minute ones in the renal cortex below the capsule. The liver might, of course, have contained microscopic tubercles though no macroscopic ones were found. The heart was distended with blood, but showed no evidence of disease. The spleen was somewhat enlarged and pulpy; it weighed nine ounces and contained one small white infarct.

In this case I think there can be no doubt that the tubercle spores were by the injury set free from the old caseous focus in the epididymis, and were carried by the venous blood to the right heart. Many of the spores were then caught up in their passage through the lungs, and thus gave rise to the miliary pulmonary tuberculosis. This theory amply explains why the pulmonary tubercles were practically all about the same size, why they were uniformly distributed throughout every part of the lungs, and why there was not evidence of general miliary tuberculosis in other parts of the body. A few of the microbes had, however, certainly passed through the pulmonary circulation, otherwise we should have found no miliary tubercles in the kidney. Moreover, by careful microscopic examination we might have found evidence of commencing tubercles in other organs.

Similar cases were observed prior to the discovery of the tubercle bacillus and gave rise to various inquiries as to the possible relation between the injury and the lung disease. A remarkable example was the following, which I have from my father, and which occurred at Bonn about 1849.

CASE 3.—An apparently healthy student, about twenty-one years of age, received some injury to one of his ankle-joints. Shortly afterwards he fell ill with an acute pulmonary affection, characterised by frightful dyspnœa and cyanosis, and, like the previously mentioned patient, died practically from suffocation about twenty-five days after the injury to his ankle. At the necropsy both the lungs were found completely stuffed with miliary tubercles, and in the ankle some caseous material was found. It was known that during childhood the patient had suffered from a disease of his ankle.

Other examples, though perhaps not quite so typical as the two foregoing, cannot, I think, be very rare—i.e., cases in which acute miliary tuberculosis of the lungs is set up by injury to some exposed part of the body which happens to be the site of previous tuberculous disease. The wonder is that such cases are not more often observed. I have not, however, heard of any case which has led to legal proceedings of any sort, though one would expect to hear that the question has frequently occurred in connexion with the foreign systems of workmen's insurance. Fortunately in Case 2 the injury which started the tuberculous dissemination was probably of a purely accidental nature.

HEADACHES:

A STUDY OF SOME COMMON FORMS, WITH ESPECIAL REFERENCE TO ARTERIAL TENSION AND TO TREATMENT.[1]

BY R. HINGSTON FOX, M.D. BRUX., M.R.C.P. LOND.,
PHYSICIAN TO ST. LUKE'S MEDICAL MISSION DISPENSARY.

I PROPOSE to set forth some of the commoner types of headache, arranged in the order of the period of life to which they belong. As the subject is large and its literature extensive I must confine myself to my own observations, which have been made chiefly upon out-patients, and these mostly women and children. My object is to inquire how far the common forms of headache are dependent upon states of general blood-pressure, and by what means they can be relieved. In infancy we can say little as to headache, yet sometimes the unappeased cry and the action of putting the hands to the ears or hair tell us with much probability of its presence. During childhood the chief causes of headache are school pressure and the rheumatic poison. The latter will come before us in connexion with a later age. School headaches are common among the children attending the public elementary schools. The boy or girl is subjected to mental stimulation under bad physical conditions—crowded insanitary homes, poor or scanty food—and the result is a frequent headache. The pain is usually frontal, worse on exertion, relieved by lying down or going into the open air; in severe cases it persists at night and may hinder sleep. When the rheumatic tendency is also present the proneness to headache is much greater. There is generally increase of arterial blood tension. Here let me say that in my experience the determination of the blood tension is not always easy. The pulse may tell us much, rather, however, by its sustained character between the beats than by incompressibility of the beats themselves. But the true tension of the pulse is often difficult to appreciate. Accentuation of the second sound of the heart, as heard over the aortic orifice, is a more certain sign, although here the observer must be mindful that a thick or thin chest wall, retracted lung, or stiffened aortic valves may greatly modify the sound. It is useful to listen also over the carotid arteries at the base of the neck. Headaches due to defects of eyesight must not be confounded with those from school pressure. The best remedies for school headaches are, in my experience, rest and cod-liver oil.

In adolescence and young adult life there are many kinds of headaches prevalent. There is, first, the rheumatic headache—i.e., that which is associated with acute or subacute rheumatism or with a well-marked rheumatic habit. The subjects are children or young adults. The pain is generally frontal, often felt on waking in the morning, and almost always worse in the early part of the day. The heart is over-acting, with a loud second sound in the pulmonic area. There is increased vascular tension. The headache is relieved by salicylates and alkalies; if any specific remedy for the pain is required antipyrin has been found effective. Closely associated with the rheumatic headache is that due to over-action of the heart. This is also a condition of plus tension, and must be distinguished from rapid heart (tachycardia) where the tension is lowered. The heart's action is increased, not only in rate, but in force; the impulse is strong, the sounds loud, and especially the second sound, as heard on both sides of the base of the heart. The subjects are often rheumatic, so that a clear distinction between these two classes of headache cannot always be drawn. The site of the pain has seemed to be more varied than in the simply rheumatic headache; often it affects the vertex, and it is sometimes worse in the evening or in the night. Vertigo is common and there may also be tinnitus aurium. Rest, iodide of potassium, and alkalies are the remedies indicated. A third large class of plus-tension headaches in young persons is found in connexion with anæmia. The throbbing or shooting frontal headache is typical of anæmia, but the site may also vary a good deal. Constipation is generally present. The remedies for the pain are those for anæmia—purgative salines and iron—and the presence of the headache need not deter us from giving iron if adequate saline treatment is used. This brings us to constipation headaches in general, still showing increased blood tension in the vessels. Constipation may cause pain in the head at all periods of life. The pain is more often referred to the forehead than elsewhere, but in many cases the vertex is spoken of, or other parts of the head. Vertigo is often complained of. Many of these cases are complicated by rheumatism or senile vascular changes. Albuminuric headaches also belong to the series of high-tension headaches. In a few cases I have observed the top or back of the head was mostly affected, and the pain, unlike that in most of the classes already mentioned, was not usually relieved by the recumbent posture at night, but was then as bad or worse than in the daytime. Migraine forms a very important class and will detain us a little longer. I understand by migraine a periodical nerve storm, the typical paroxysm consisting in severe pain in one brow or temple, giddiness, nausea, often vomiting, and sometimes disturbances of special senses, such as hemiopia or transient blindness, vibratile spectra, numbness of parts of the surface, &c. The pain is in some cases symmetrical. Such attacks occur at any age from childhood onward, but are less common after the climacteric period. In the majority of my cases the arterial tension has been increased, but in one notable case it was not so; this was the worst case I have ever seen, the attacks were very frequent and severe, reducing the subject, an intelligent professional man, to misery, and in his vessels the blood tension was very low. Instances of megrim are common in women with a gouty inheritance, and whose urine is over acid, often laden with urates, and depositing uric acid crystals. Such women have increased vascular tension and their catamenia are profuse. They are liable to strange pains, which puzzle their medical attendants, in the back, the side, or about the sternum. In the treatment of migraine we must, in the first place, deal with the patient's general condition. Saline purgatives, a mild mercurial course, potassium iodide, sodium salicylate, or alkalies are often indicated. There are generally bad habits of diet in these cases needing to be set right, also want of exercise, constipation, &c. For the relief of the paroxysms antipyrin and phenacetin have often been in my experience successful. Alkalies sometimes induce the attacks, perhaps by rendering the uric acid in the tissues soluble. But I am accustomed to rely much upon cannabis indica, having had a pretty large experience of this remedy. The extract, often combined with cascara sagrada, has controlled many, if not most, cases of migraine. The co-existence of a tendency to menorrhagia is a further reason for the use of Indian hemp. But it is a remedy which requires careful adjustment for each case, both from the varying susceptibility of different subjects to its influence, and I think also from the varying strength of the drug itself. I prefer to use the fresh extract, and have in a good many instances given it to the point of intoxication. This, however, does no permanent harm. In the case of a woman convalescent from acute lung catarrh attacks of migraine were occurring daily; one-fourth of a grain of the extract was prescribed, and she took by mistake two doses at once, half a grain in all; intoxication followed, as shown by strange delusions, and unconsciousness for two hours. On recovery she remained free from headaches for ten days. In another case the dose of the drug was gradually increased to seven-eighths of a grain, and then, a hearty meal following the administration, symptoms of intoxication came on, with hysterical excitement. The patient declined further use of the remedy, but was persuaded later to resume it, and the attacks of migraine were both distant and slight when she persevered with it. In a third case nearly half a grain used to cause some symptoms of intoxication when taken upon an empty stomach—"pins and needles," stupor, and strange feelings being complained of; but these were delayed for three or four hours when the dose was taken after a full meal. In the case of severe migraine alluded to with low blood tension cannabis only aggravated the patient's sufferings—I believe it is useless except for high-tension states—nor did caffeine, bromides, or salines help him, and change of air brought only a short respite. The patient left me unrelieved. I heard of him a year later; he had consulted other physicians, but the attacks continued much the same.

I have notes of about a dozen cases of epilepsy in which headache was a prominent symptom, but it varied much in site and other characters; in several of the cases the pain

[1] Introduction to a discussion at the Hunterian Society, April 28th, 1897, vide THE LANCET, May 8th, 1897, p. 1275.

Digitized by Google

was worse in the evening or during the night. With regard to neuralgic headaches, besides those which are localised in the area of a cutaneous nerve on one side of the head and some of which are reflex to ocular, dental, or nasal conditions, there are a few cases upon my list of severe habitual headache of long standing in women which do not seem to fall under any other category. The pain was in the back of the head and nape of the neck, coming forward over the vertex. There was plus tension in the arteries. Relief was obtained from cannabis, with alkalies or salines.

I now pass to some forms of headache, still in younger adult life, in which the arterial tension is lowered. The principal of these is the headache associated with tachycardia, or heart-hurry. This condition may be contrasted with that of the over-acting heart previously alluded to. The heart contractions are in both frequent, more so in tachycardia, but whilst the over-acting heart beats forcibly against tense blood-vessels, in tachycardia the beats are simply quickened, the second sound is weak, and the vessels are relaxed. The breathing is quickened, the skin perspires inordinately, and there is incapacity for much exertion, physical or mental. Graves's disease may be looked upon as tachycardia in its full development, but all degrees of the condition in a slighter form are very common—more common, I venture to think, than used to be the case. The headache of heart-hurry is again various in its location, frontal, vertical, posterior, or several of these combined. The head is often flushed or hot, and the pain is commonly worse at the catamenial epochs; it is usually relieved by quiet, by recumbency, and by drinking tea. Caffeine quells some of these headaches, and the iodide and bromide of potassium relieve others. Headache in alcoholic subjects may be coincident with plus or minus blood tension. When it is due to the direct action of alcohol the vessels are relaxed, the tension is low, and the condition is closely similar to that of tachycardia. On the other hand, the indirect and remoter effects of alcohol, by hindering elimination, increase the blood tension and contribute a large quota to the plus tension headaches of middle life, which we shall consider presently.

There is a well-marked type of headache which may be termed congestive. The head is flushed and hot, and the carotids often pulsate visibly, whilst the hands and feet are cold; the pain is frontal, or all over the head when severe, and is described as bursting, throbbing, beating, or shooting in character; it often begins on rising in the morning and is worse after exertion or meals. The subjects are well nourished, and in women the catamenia are scanty or absent. The blood tension, contrary to what might at first sight be supposed, is somewhat diminished. This form of headache seems to be very well relieved by caffeine. One woman, aged twenty-three years, came again and again during many months for her five-grain doses of the citrate of caffeine. "It seems," she said, "as if I cannot do without the medicine; I get relief half-an-hour after I take it." Caffeine is the most useful remedy we have for low-tension headaches. Antipyrin and phenacetin relieved some of the cases. Mention may here be made of the headache due to cough. It is, I think, of much the same type as the last; the pain is frontal or vertical and the head is hot. The blood tension is doubtful; sometimes, if not generally, lowered. Observations on this head are complex; in one case the tension was usually increased, but during a paroxysm of cough it was diminished and the vessels relaxed. The headache of influenza and of enteric fever belong also to the low-tension class.

Going on now to the headaches of middle life, it will be convenient to speak here of those attendant upon heart disorders, although many of these are found also at earlier ages; those belonging to old age will be considered later. My records of heart cases are too few to enable me to draw many conclusions. In the early stage of rheumatic heart disease, with or without slight valvular lesion, the vascular tension is generally heightened, and headache is very common. It may be thought that mitral regurgitation must lower the tension; when the reflux is large it probably must do so, but in my experience a small leak may coincide with tightened vessels. The site of the pain may be in any part of the head, and the headache is much the same as that already described under the heading of rheumatic. Cannabis relieves some of these cases. Headache occurs also in the latter stages of mitral disease when the tension has sunk; it attends also, often severely, aortic incompetency. Mitral stenosis caused a characteristic headache in six well-marked cases. It was generally located at the vertex, often throbbing in character, came on on waking or rising, and was increased by exertion or by taking food. This headache was relieved, as is usually the case, on lying down; on the other hand, I have noted several cases of feeble, irregular, or irritable hearts, with headache aggravated by the recumbent posture. We shall see that this is very often the case with the high-tension headache of old age. Menorrhagia is commonly attended with headache, generally frontal or vertical and throbbing. I think the blood tension is most often heightened. Cannabis indica is especially indicated. Arterial tension is apt to rise during the middle period of life. The causes of this change, as they are seen in the well-to-do classes, are quite familiar—over-eating, alcohol, sedentary habits, and the gouty constitution. From these it results that the blood becomes charged with effete matters and the vessels thickened, the heart usually hypertrophies, and for long no serious difficulty hinders the due circulation of the blood. In the poorer classes another set of causes are at work—bad air, scanty and poor food, long hours of manual labour, shortened rest, and chills. These depressing causes generally, in my belief, lead to contraction and thickening of the arteries, or, I would say, to premature age of the vessels; for among the poor, at least, degenerated vessels are among the normal results of old age. Then arises the question, Will the heart hypertrophy in response to the greater pressure against which it has to act? In many cases it does so, but in others it fails to hypertrophy because its tissues are badly nourished and there is general lack of strength. Instances of this condition are often to be seen amongst the poor in broken-down, middle-aged men and women. The vessels are thickened, but the heart is dilated and feeble, with weak second sound; there is asthenia and short breath, and the pulse has nearly that character described by Broadbent as "virtual tension." Headache is very common amongst the gouty and those whose excreting organs are working ill—a high-tension headache, to be relieved by mercurial purgatives, salines, alkalies, potassium iodide, and perhaps cannabis. The poor with their high tension bred of want and fatigue suffer perhaps less in headaches, nevertheless many such cases have come before me. I shall refer to this again in connexion with old age. There is, however, one class of headaches in middle life of a kindred type to the foregoing—that which affects women about the climacteric epoch. The pain is commonly referred to the vertex, and is often spoken of as bewildering or as aggravated by noise or worry; vertigo is frequently complained of. The blood tension is increased. In other cases which showed symptoms of hysteria or mental depression, with headache, at this epoch the tension has been noted as lowered.[2] Bromides are the most useful drugs; cannabis relieves some of the cases.

It remains to speak of the headaches of old age. The poor age early; at fifty-five they are old, at sixty or sixty-five thickened vessels, tortuous temporal arteries, thin and wrinkled skin, and arcus senilis tell that the full age of the Psalmist has virtually been reached; and it is by reason of strength if they compass seventy years or seventy-five. Amongst over 12,000 patients at St. Luke's Dispensary I have not seen probably half-a-dozen over eighty years of age. The blood now circulates through inelastic tubes, no longer with the easy flow of health—a stronger propelling force must urge it forward. The heart responds and hypertrophies; there is heightened tension. But as the vascular changes go on there comes a time when the heart muscle can no longer easily meet the strain. There is increased action, making up in frequency of beat for the lessened power; there is præcordial distress and bad breathing. This condition is well described by Balfour in his book, "The Senile Heart"; also by Clifford Allbutt. Again, the heart may be vanquished in the strife, its cavities may dilate, and its action become rapid and irregular, with low tension in the arteries. And life may yet be prolonged for years, but it is life at a lower level, the sum of the action of feeble organs, when the flowing blood stream has fallen to a mere brook, meandering through the marshy tissues. Now whilst the tension is increasing monthly and yearly it is not to be thought that the various organs can work in comfort. Amongst the symptoms of

[2] Sir W. Broadbent states that high tension is the rule in melancholia. In the hystero-mental depression of the poor I have often found it lowered.

Digitized by Google

dis-ease headache is common, in site frontal, vertical, or posterior, often throbbing, and apt to be worse in the night. One patient has "dreadful sensations" in the head at night, another is awakened daily by the pain at 3 A.M., and it lasts until near tea-time. When the heart is distressed and labouring against pressure these pains become in some cases violent, "splitting," burning, and especially affect the night time, hindering due sleep. The bowels are almost always costive, the hand is shaky, and the last joints of the fingers are enlarged (Heberden's nodes). Headache is also common in the last stage of senile heart, when the blood tension is low, the heart dilated, and its action irregular; there are also giddiness and often faintings. The treatment of these headaches is that of their associated heart conditions. Mercury is perhaps our sheet anchor in the relief of the high tension of old age; salines and potassium iodide are of like help. I once gave nux vomica to a person aged eighty-eight years with thickened vessels. She begged it might be left off. "It strings me up so, sir; I cannot bear it." As has been well said, Epsom salts are the best tonic for the aged. A woman, aged fifty-seven years, came to me six years ago; she had chronic bronchitis, dilated heart, breathlessness, and œdema of the legs. I thought she was past cure, but sent her to bed and ordered her to take a course of sulphate of magnesia and grey powder. She came in recently, to my surprise, having lived in tolerable health these six years. "Ever since," she said, "you told me to take the salts I have flown to them whenever I was down; nothing ever does me as much good as the salts." I believe she is right; the saline has eased the vessels and given the heart time to hypertrophy, as it has done. In the low-tension headache of failing heart power digitalis, strophanthus, and the like are of chief use.

The chief points I have sought to bring forward are these:—1. The state of the arterial blood tension is an important factor in many forms of headache. Increased tension is the rule, but there are some well-marked types of low-tension headaches. 2. In the treatment of headache the first thing is to treat the cause or the disorder which is associated with it. 3. The remedies which lower the general blood tension are often useful for high-tension headaches, and those which raise tension for the low-tension forms. 4. Of specific remedies, cannabis indica is of value in most high-tension headaches and caffeine citrate in many of those of low tension. Antipyrin, phenacetin, and acetanilide may be useful in both, but chiefly when the tension is high.

Finsbury-square, E.C.

A CASE OF

PUERPERAL SEPTICÆMIA TREATED WITH ANTI-STREPTOCOCCIC SERUM; DEATH.

BY J. D. RAWLINGS, M.B. LOND., M.R.C.S. ENG.,
LATE HOUSE PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL; HOUSE PHYSICIAN, GENERAL LYING-IN HOSPITAL, ETC.

MANY cases of septicæmia, puerperal and otherwise, have now been published in which the use of antitoxin has been followed by extraordinary recoveries, but I have seen few in which antitoxin has been tried and apparently failed. As negative results in such matters are as important, though not so gratifying, as positive ones, I offer the notes of the following case, in which serum treatment was begun three days after the onset of the disease and was continued until the patient was moribund, the case going steadily downhill all the time. On the only other occasion when I had the opportunity of trying anti-streptococcic serum the result was the same, but in that case the treatment did not have a fair chance, as it was not begun till twelve hours before death.

A primipara, aged twenty-four years, was admitted, on Aug. 24th, 1896, into the General Lying-in Hospital, Lambeth. Pregnancy had reached full term, and the patient was said to have been in labour for fifty-four hours. On the evening of admission an unsuccessful attempt had been made to deliver with forceps in the patient's own home. On admission to hospital the patient was in good general condition, showing no constitutional symptoms or local signs of obstructed labour. Fairly strong pains were occurring every ten minutes. The fœtal heart was 156. Pelvic measurement showed a slight degree of general contraction, thus:—Distance between the iliac spines, 9⅝ in.; distance between the iliac crests, 10½ in.; external conjugate diameter, 7 in.; diagonal conjugate diameter, 4¼ in.; and true conjugate diameter (measured after labour), 4 in. Immediately after admission a vaginal douche of perchloride of mercury (1 in 2000) was given. Two hours later chloroform was given and forceps applied. There was no unusual difficulty about delivery; the head was brought from the brim to the perineum in half an hour; there were no lacerations. The child, weighing seven and a half pounds, was born alive. The placenta was expressed from the vagina. The total amount of hæmorrhage during and after labour was twenty ounces. After delivery the uterus and vagina were very thoroughly douched with perchloride of mercury (1 in 2000). A little later the temperature was 99·2° F. and the pulse was 84. On the 25th, twelve hours after delivery, the temperature was 103·6° and the pulse 120, no rigor having occurred. On the 26th the temperature varied from 101·4° to 104·2°, the pulse from 122 to 140, and the respirations from 28 to 36. The patient was sweating freely and had a headache, but no rigors. In the evening there was found to be some superficial sloughing of the lower part of the vaginal wall and vulva posteriorly. The lochia were normal in appearance, odour, and quantity. The vagina was douched with creolin and the vulva powdered with iodoform. Four ounces of brandy per day were ordered. The appetite was good and the patient slept well at night. On the 27th the patient was bright and cheerful, the temperature varied from 102·4° to 103·4°, the pulse was 126, and the respirations were 28. The bowels were very freely relieved twice; the tongue was clean; there were no signs of pneumonia, pericarditis, or peritonitis, but the heart's apex was felt one and a half inches outside the nipple line and hæmic murmurs were heard at the base; the lochia were still normal; the breasts were flaccid. The dose of brandy was increased to six ounces, and digitalis and caffeine were ordered. In the evening a little chloroform was given, and the uterus was scraped with a blunt flushing curette; only a few shreds came away. During the operation creolin (1 in 200) was flowing through the curette; afterwards a quart of plain water was run through the uterus, and this was followed by two quarts of perchloride (1 in 4000). After the curetting the temperature suddenly fell to 97·8° and the respiration became infrequent and sighing, but the pulse was 100 and of good volume; the extremities were warm and there was no increase of pallor. The patient only slept two and a half hours. On the 28th the patient was still very bright and cheerful. The temperature gradually rose during the morning to 103·2° and the pulse to 120. At noon the uterus was douched with perchloride, when the vagina was looking better than it had done before. At 2 P.M. 9 c.c. of streptococcic antitoxin were injected. In the evening the patient was seeming a little better in herself, but the pulse was intermittent. The temperature was 102·8°. The uterus was douched with perchloride, when a few sloughs came away and the vagina looked much more healthy than before. A further 9 c.c. of antitoxin were injected. The patient slept for two hours after half a grain of morphia. On the 29th the patient said that she felt better, but she looked worse, and certainly was so. The temperature varied from 102° at 2 A.M. to 98·6° at 10 A.M., twenty hours after the first dose of antitoxin; the pulse was generally 136, but very variable in rate and very irregular. The tongue was slightly furred but moist, and the appetite was good. Two liquid offensive motions were passed. The lochia were normal, but diminished in quantity. The dose of brandy was increased to twelve ounces. Antitoxin was injected at 1 P.M. and again at 9 P.M., but no fall in temperature occurred. Digitalis, strychnine, and caffeine were given hypodermically. In the evening the patient complained of intense pain in the back, which persisted almost without remission till her death, and was unaffected by morphia. She slept a very little after the administration of one grain of morphia. On the 30th the temperature ranged from 100·4° to 101·4°; the pulse was 200. A cadaveric odour was present. The patient scarcely slept at all at night, in spite of morphia, which was given hypodermically in doses of half a grain, until three and a half grains had been given in eight hours. On the 31st the temperature was 103·4°. The pulse was 208 and scarcely perceptible at the wrist. She was not in pain for a short time in the morning. She asked for solid food at dinner-time and ate a quarter of an ounce of cold beef and an ounce of mashed potato and drank half a glass of ale. In

Digitized by Google

the evening she ate a whole pear with avidity. There was twitching of the supinators of the left arm. On Sept. 1st the movement of the abdomen on respiration was a little impaired, and there was slight resistance in the left flank. In the evening the twitching increased, hiccough occurred, food was refused, and the patient died at midnight.

Necropsy.—Post mortem the top of the uterus was found to be one and a half inches below the umbilicus, and the weight of the uterus was 14 ounces. There was no general peritonitis, but on the left half of the posterior aspect of the uterus the peritoneum was injected. Douglas's pouch contained about two drachms of free pus. There was no recent lymph or adhesions. Inside the uterus was some blood-stained thin pus, but no retained membranes or placenta. When the pus was sponged off the surface appeared healthy. The upper part of the vaginal walls was healthy, but contained pus like that in the uterus. There was some sloughing of the lower part of the posterior vaginal wall and the posterior part of the vulva. The true conjugate measured 4 in. and the transverse diameter of the brim was 4⅝ in. There was no thrombosis or pus in the iliac veins. There was no endo- or peri-carditis. The lungs, pleuræ, and spleen were natural.

Remarks.—Apart from the antitoxin treatment there are some interesting points in the case. It is somewhat unusual for so acute a septic process to be unaccompanied by any rigors. The case is a striking example of the extreme value of a high pulse rate in the diagnosis of puerperal fever. It is not uncommon during the first days of the puerperium for the woman to get a rise of temperature and headache without any localising signs anywhere and with a pulse well under 100. Such symptoms need cause but little anxiety, and generally disappear after a purge. With a pulse of 120, however, the same symptoms are of the utmost gravity. In the present case, for example, the pulse rate was at first the only indication that the fever was of a serious nature, there were no rigors, the lochia were sweet and plentiful, the patient was bright and cheerful, the tongue was clean and moist, and the appetite good. On the other hand, the bowels were loaded, and that might have been accepted as an explanation of the fever and headache. And yet there was an acute septic process going on which was to terminate fatally on the eighth day. In this connexion it is interesting to note that during the twenty hours following the first dose of antitoxin the temperature fell from 103·2° to 98·6°, but as this was unaccompanied by any fall in the pulse-rate it was not regarded as a sign of improvement, but merely as a remission of temperature such as occurs naturally in septic cases; and this proved to be the case. Seeing the extreme importance of early treatment in puerperal sepsis, and the great value of the pulse-rate as a means of diagnosis in the early stages, I would lay down the following rule: if in the first three days of the puerperium the temperature rises without obvious cause to 102°, and is accompanied by a pulse-rate of 120 or more, the case should be regarded provisionally as septic, and if the temperature and pulse-rate are maintained for twelve hours and still no satisfactory cause is discovered the uterus should be curetted and douched without further delay. This was not done so early in the above patient's case because her condition was at first thought to be due to septic absorption from the vagina, and it was hoped that vaginal douching would be sufficient; there would, moreover, have been the risk of carrying septic matter from the vagina into the uterus on the douche tube. Dr. Champneys, in his lectures, and Professor Byers, of Belfast, in a paper read before the British Medical Association last July, emphasise the importance of the pulse-rate in these cases; but the point is, I venture to think, not sufficiently insisted on in textbooks. Pain in the back of such intensity as in this case is unusual, and nothing was found to account for it before or after death. The patient's tolerance of morphia was extraordinary; in one night she took three and a half grains hypodermically; the tolerance was genuine, for different samples of morphia were used. As so often happens in fatal septic cases, the condition known as euphoria was well marked; although she was being rapidly killed by acute sepsis the patient felt well, was in good spirits, and until the pain in the back began had no idea that she was seriously ill. Six hours before death she recognised her husband and talked rationally to him. No rash of any kind occurred.

I am indebted to Dr. Boxall, under whose care the patient was, for permission to publish the case.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF MYXŒDEMA.

BY ERNEST A. DENT, M.B., C.M. EDIN.,
SENIOR RESIDENT OFFICER, DEVONSHIRE HOSPITAL, BUXTON.

A WOMAN, aged forty-five years, was admitted to the Devonshire Hospital, Buxton, on March 13th, 1895, suffering from pain and swelling of the joints, from which symptoms rheumatism had been diagnosed. On examining the patient I observed signs which led me to inquire for a history bearing on myxœdema, the chief of these being a dull expressionless face, some loss of hair, thickening, dryness, and scaliness of the skin, and the characteristic hesitating speech, manner, and gait. The patient complained of pain in the fingers, and pain and swelling in the feet, dryness of the skin, and absence of perspiration, also of increasing weakness and loss of memory, with want of interest in, and fitness for, any employment. She stated that these symptoms commenced about four years before and attributed them to a shock she received at that time. The family history was as follows. Three members—viz., her maternal grandmother and two of her sisters—were insane, and one brother of the patient was affected with rheumatism.

Treatment. — The patient was ordered thyroid gland tabloids (five grains) thrice daily, and, in addition, half a pint of the Buxton mineral water twice daily and mineral water baths up to the waist at a temperature of 100° F. for ten minutes every other day. After taking the tabloids for a few days she complained of giddiness, and there being some weakness of circulation a stimulant mixture was prescribed. When she had been in the hospital a little more than a fortnight she was very much better in every respect, a week later she said that she felt tired and her legs ached, and in about a fortnight after this she complained of feeling faint. The tabloids were now reduced to one daily. There was continuous general improvement in her condition almost from the commencement of treatment, and when she left the hospital, seven weeks after admission, her face had a much brighter expression, the thickening was much reduced, leaving her skin comparatively soft and wrinkled, she perspired freely, and her memory and manner were much better. She was recommended to continue taking one tabloid a day after her discharge.

As the patient has lately been re-admitted here I am able to give further particulars about her. She tells me that she went on taking one tabloid a day for about nine months after leaving (two years ago), and during that time she continued to improve. Since then she has not been so well, having "caught cold," and as she had another "trouble" she was very depressed and felt generally weak. About six weeks ago she had an attack of sickness and diarrhœa (attributed to eating oysters), and when recovering from this she sought admission here. Perspiration had ceased, she felt very weak, and was suffering from constipation and slight dizziness; the skin was very dry. She was ordered one tabloid twice daily and a stimulant mixture, and was, a fortnight later, very much better.

Remarks.—The family history, the patient's statement that the symptoms were caused by a shock, the rapid improvement under treatment, and the subsequent history, seem to me to be points of interest in this case. I think the favourable result obtained from the tabloids on her first visit here was aided by the warm baths, and the patient said that she felt much comfort and benefit from them. The later notes on this case tend to confirm the view, that in the case of myxœdema, although the symptoms have subsided, the thyroid treatment should not be entirely discontinued.

I am indebted to the honorary medical officer, under whose care this patient has been, for permission to publish the case.

Buxton.

A CASE OF LACERATION OF THE TONGUE.

BY ALFRED EVANS, M.R.C.S. ENG.

I WAS recently called to attend a boy who had been injured when playing cricket. It appeared that whilst

Digitized by Google

batting in a match he attempted to "pull a ball to leg," but the ball, instead of travelling to that vaguely-defined district, unfortunately landed on his own oral region. On examination the right side of his mouth was found to be very swollen and contused and there was considerable hæmorrhage. He was able to open his mouth with some difficulty, and it was then seen that the cricket-ball had fractured his right canine and lateral incisor teeth, breaking them off flush with the gum. The fragments of teeth had been driven with considerable force into the lingual muscles, the points of entry being near the frænum, the incisor fragment being forced out on the dorsum and easily extracted, leaving a punctured wound through the tongue, along which the probe easily passed from the sublingual to the dorsal surface. The canine tooth, however, had made a channel for itself extending from the attachment of the frænum into the muscular tissue, and could be felt embedded in the tongue near the middle line opposite the last molar tooth of the same side, and the probe was passed one inch and three-quarters before it reached the foreign body. Pressure and manipulation with the finger failed to remove it, so, having applied a spray of ethyl chloride along the track of the tooth it was grasped by dressing forceps and pulled out by the route by which it had entered. The tongue was considerably lacerated, but no artery of any importance was injured, and rinsing the mouth with iced water and, afterwards, frequent ablutions with a weak permanganate solution, together with abstention from all solid and hot foods, resulted in a rapid recovery, and, excepting a little soreness, the organ has now quite healed. The rarity of this form of accident is my excuse for reporting the casualty.

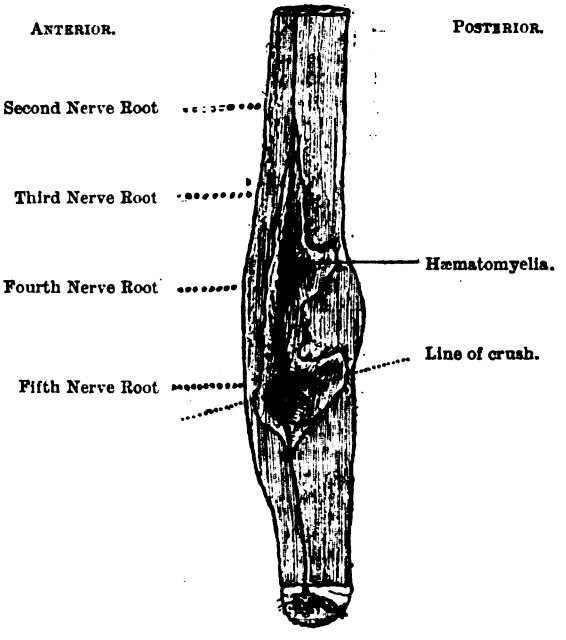
Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

NORFOLK AND NORWICH HOSPITAL.



A CASE OF TRAUMATIC HÆMATOMYELIA; NECROPSY; REMARKS.

(Under the care of Mr. C. WILLIAMS.)

THE very definite symptoms to which a hæmatomyelia gives rise when uncomplicated by any other injury of the spinal cord enable a diagnosis to be made of the exact seat and character of the lesion. In the following case careful observation made the diagnosis certain and effectually prevented any idea of laminectomy, which could have been of no service. For the notes we are indebted to Mr. H. A. Ballance, house surgeon.

A woman, aged seventy years, was admitted into the Norfolk and Norwich Hospital at 9 A.M. on Feb. 3rd, 1897, having at 7.15 A.M. been found in an unconscious condition at the foot of a flight of nine stairs. On admission the patient was quite unconscious; the pulse was 64 and the respiration was 16. There was no stertor. The pupils were very contracted and equal, and showed no reaction to light. The knee-jerks were present. The breathing was solely diaphragmatic. There was a cut on the left side of the forehead about an inch vertically above the outer canthus and two-thirds of an inch long, exposing the pericranium. A fissured fracture could be felt at the bottom of this wound going obliquely downwards and inwards. There was, in addition, a scalp wound one and a half inches long at the back of the right parietal bone down to the pericranium, but the bone was not fractured. There was no irregularity about the cervical spine. Towards the evening of the day of admission the patient roused up a little, but not sufficiently to talk. There was no sickness, the right arm and leg were rather rigid, and the knee-jerk and plantar reflex were much better marked on that side. The left side of the body was quite flaccid. The breathing was rather noisy; the pulse was 56 and regular; and the rectal temperature, which on admission was 96° F., rose to 99·4°. On the 6th the patient remained in much the same condition and had roused sufficiently to say "No," "Yes," and "What," but she did not answer questions connectedly. The temperature varied from 100° to 101°, the respiration was 20, and the pulse ranged from 70 to 80. The pupils still remained pin-point in character. She lay on her back in a state of absolute flaccidity, all four limbs being motionless and the arms lying by the sides. Costal respiration was quite absent. There were no reflexes in the lower limbs. There was entire loss of sensation from just below the level of the clavicles downwards, but the exact limiting line could not be defined owing to the patient's dull mental condition. It was evident, however, that the skin area supplied by the fifth cervical root was quite devoid of sensation and that the anæsthesia extended from this region downwards. The catheter had to be used, as there was retention of urine and the bowels did not act unless purgatives or enemata were given. The urine contained neither albumin nor sugar. On the 8th the general condition and the state of the temperature, pulse, and respiration remained the same. The plantar reflexes had re-appeared, the right being better marked than the left. In the evening of the 9th she was not so well. The temperature had been rising all day, so that at 8 P.M. it was 105° in the rectum; the pulse was 92, and the respiration was 40 and shallow. She was more comatose and could not be roused at all. There was complete flaccidity. No reflexes, tendon or plantar, could be elicited. The patient died at 6.30 A.M. on the 11th, having gradually sunk since the 9th. The temperature had continued rising, so that two hours before death it was 108° in the rectum, and ten minutes after death, 109.2°. The pulse reached 100 for the first time on Feb. 10th.

Necropsy.—A post-mortem examination was made at 4.30 P.M. on the day of the patient's death. The fracture of the skull in connexion with the wound on the left side of the forehead was found to be two inches long, and it passed obliquely down through the anterior part of the temporal fossa into the anterior fossa of the skull base. There was no depression of bone, laceration of the brain or hæmorrhage on its surface. There was a good deal of cerebro-spinal fluid in the ventricles, and the cut cerebral surface appeared to be more moist than usual. On exposing the cervical spine from behind, the column appeared to be normal and even after removal of the laminæ and division of the theca the spinal cord looked perfectly healthy, and there was an entire absence of meningeal hæmorrhage. On passing the finger down the cord, however, a portion opposite the upper border of the fifth cervical vertebra felt quite soft, as if pulped. The cord having been removed and divided vertically in the sagittal plane, a hæmatomyelia involving its central parts, was seen to be present opposite the bodies of the third, fourth, and fifth vertebræ inclusive, and of the form shown in the illustration.

Longitudinal sagittal section of the cervical spinal cord, showing the hæmatomyelic cavity in the centre and the levels of the cervical nerve roots.

Digitized by Google

This cavity was filled with broken-down blood-clot, the spinal cord being softened around it. It measured one and three-quarter inches vertically and tailed off above and below along the central canal. The largest part of the cavity was opposite the upper border of the fifth cervical vertebra and the fifth nerve root. The upper tailed extremity reached to the level of the second nerve root. Posteriorly the layer of nervous matter bounding the cavity measured one-twentieth of an inch in thickness and anteriorly one-eighth of an inch. The disorganisation encroached more into the right than the left lateral region of the cord. The level of the crush was oblique, as shown in the figure, and exactly opposite the fifth nerve root. On examination of the spine the posterior common ligament was seen to be intact, but the anterior was ruptured opposite the body of the fifth vertebra, which was horizontally fractured at quite its upper part, only a scale of bone having been detached and remaining adherent to the disc between the fourth and fifth bodies. There was no fracture of the articular processes. The lungs were well aerated all through and showed no excess of fluid in the tubes; this was singular considering that the breathing had been solely diaphragmatic for eight days. The other organs were healthy.

Remarks by Mr. BALLANCE.—The case is interesting both from the comparative rarity of hæmatomyelia and from the typical symptoms of injury of the cervical cord that were present. The level of the injury was easily diagnosed during life. It was evident that the fifth cervical root had not escaped because of the cutaneous anæsthesia and the paralysis of the deltoid group of muscles, and that the fourth was intact because of the persistence of diaphragmatic breathing. From the absence of the irritative symptoms commonly met with in hæmorrhage into the meninges it was concluded that the damage was probably limited to the cord itself. The contraction of the pupil and the slow pulse, due, as is well known, to the paralysis of the pupil dilator and cardio-accelerator fibres respectively in their course down the spinal cord to the upper dorsal region, were very noticeable. The exact nature of the injury was dislocation with recoil, the upper four cervical vertebræ with a part of the fifth having passed forwards on those below them and then sprung back again into their former position, bruising the cord during the process. The situation of the injury in the present case entirely accords with Thorburn's experience. He states[1] that traumatic hæmatomyelia usually occurs opposite the fourth, fifth, and sixth cervical vertebræ, and that he has not met with a single case in the dorsal or lumbar regions, a circumstance which he adduces to prove that this form of injury is due to dislocation with recoil, and not to what is vaguely called concussion. Necropsies are very uncommon in this form of hæmatomyelia, as the majority of cases recover. It is to be regretted that this patient also sustained a head injury, as otherwise a much more detailed clinical picture might have been obtained.

Reviews and Notices of Books.

The Physiology and Pathology of the Cerebral Circulation: an Experimental Research. By LEONARD HILL, M.B.Lond., Hunterian Professor, Royal College of Surgeons of England. London: J. and A. Churchill. 1896. Price 12*s*.

THE profound and exhaustive researches upon the cerebral circulation which Dr. Leonard Hill expounded in his Hunterian Lectures for 1896 did much to throw light upon a question that is amongst the most difficult for the physiologist to determine. The re-publication of these lectures in the form here presented will therefore be heartily welcomed, for in them the reader is led step by step towards the explanation of the phenomena of the pathological states of anæmia and compression. The conditions under which the circulation is carried on within the closed cavity of the cranium are not to be explained on anatomical grounds or even deduced from clinical observation. They can only be investigated by experiment, and it is because the experiments carried out for this purpose by the author of this work were so skilfully planned and so well adapted to discover the actual conditions that they have been so fruitful. For there is no question that these physiological researches have led to a very material change in the point of view from which the phenomena of cerebral anæmia and compression must be regarded. Commencing with the study of the movements of the brain, cardiac and respiratory, Dr. Hill passes to consider the *rôle* of the cerebro-spinal fluid, establishing the important fact that in normal states the tension of this fluid is equal to that of the venous pressure. He shows that the subdural space is physiologically one with the subarachnoid, and that fluid can pass readily from one to the other—a fact which, though anatomically disputed, yet is confirmed by the teachings of pathology. It is instructive to learn that withdrawal of this fluid is at once followed by serous transudation from the blood, and that it is impossible for any increase of the cerebral tension to be transmitted by the cerebro-spinal fluid owing to the tendency to equilibrium between the intravenous and subarachnoid pressure. Dr. Hill also shows that it is possible to irrigate the brain and spinal cord with ease, his final conclusion to this section being the suggestion "that in such a pathological condition as meningitis irrigation of the meninges might be employed." He adds: "The operation could be as easily and safely carried out as that of irrigation of the peritoneum." The next section deals with the cerebral circulation. Whilst confirming the general truth of the Monro-Kellie doctrine that the volume of blood in the brain is almost invariably constant, Dr. Hill, by means of most carefully devised experiments, has studied the relations of the intra-cranial circulation to that of the general circulation. In some respects his results run counter to those of other experimenters, but he gives good reasons for such divergencies, and affords much matter for thought and inference. One interesting outcome of this research is the evidence that the circulation within the skull is uncontrolled by vaso-motor nerves, but that it is influenced solely by the variations in the general arterial or venous pressure. In so far as this is under any nervous control, it is through the splanchnic nerves that the cerebral circulation is to be modified, the circulation being accelerated by a rise in arterial pressure and slackened by a fall in that pressure. Owing to the conditions within the skull it is not possible for the intracranial pressure to be more than momentarily raised above that of the cerebral venous pressure. "The cerebral circulation passively follows every change in the general circulation. Every change in the position of an animal from the influence of gravity on the vascular system affects the cerebral circulation. Every variation in respiration and every muscular movement is followed by passive changes in the circulation of the brain. Every heart-beat and every respiratory undulation is exhibited on the tracings of the cerebral venous or intracranial pressures. Compression of the jugulars or the abdomen causes a marked rise in cerebral venous pressure, and muscular movements of the neck by pressure on the jugular veins are sufficient to affect the cerebral circulation. Every stimulus that enters the organism and affects the general vaso-motor centre produces a passive effect on the cerebral circulation. Each pleasurable emotion raises the general blood pressure and increases the blood-flow through the brain, and each painful emotion brings about the opposite result. It is by means of the splanchnic area that the blood-supply to the brain is controlled" (p. 74). This passage illustrates the prime fact learnt by this research—namely, the close dependence of the circulation within the skull upon the conditions obtaining in the body generally, and at the same time affords physiological reason for facts of daily experience. A section is devoted to the discussion of the influence of the force of gravity on the

[1] Surgery of the Spinal Cord. By William Thorburn. 1889.

Digitized by Google

circulation, and opens up many questions of practical moment. The main lesson to be learnt is that the effect of gravity is compensated for by the splanchnic vaso-motor system, and that the extent of this varies in individuals. The phenomena of syncope and shock are explained, and the value of abdominal compression in restoring the subjects of these conditions, or those of cardio-vascular paralysis from chloroform poisoning, is well exemplified. The application of these physiological studies to the subjects of cerebral anæmia and cerebral compression forms two most valuable and interesting sections of the work. The conditions for the production of cerebral anæmia are explained in detail and the effects of narcotics as well as the phenomenon of sleep are discussed, the great share taken by the splanchnic vaso-motor apparatus being again dwelt on. As regards compression it is shown that the brain does not transmit pressure equally in all directions, and that there is "complete pressure discontinuity between the cranial and vertebral cavities" owing to the viscosity of the brain substance, the tentorium cerebelli, and falciform ligaments, and to the plugging of the isthmus tentorii cerebelli and the foramen magnum by the translocation of the brain mass. The symptoms of compression are mainly those of anæmia of the bulb, and are due to the cessation of the blood flow. A small opening into the skull does not necessarily relieve compression, for what is required is to allow of "an equivalent compensatory expansion of the cranial contents," which may not take place owing to the viscosity of the brain mass. These are some of the inferences drawn by the author, but we fear that it is not possible to do him full justice without extensive citation. We would, however, strongly commend his admirable monograph—which is a model of clear exposition and sound reasoning—to the attention of physiologists and pathologists. They will find in its pages much material for consideration, and many an obscure point in cerebral pathology and in the symptomatology of cerebro-spinal disease will be made more clear. Nor can these studies fail to produce good fruit in regard to the more rational and hopeful treatment of disturbed conditions of the cerebral circulation.

LIBRARY TABLE.

Oban: a Health and Holiday Resort. By EDWIN BAILY, M.B., C.M. Edin., Medical Officer of Health of the Burgh. Oban: Hugh McDonald. Pp. 48.—Increased facilities of access, both by railway and steamboat, as well as the natural advantages of its situation, have rendered Oban one of the most popular summer resorts in the Western Highlands of Scotland. It can be easily reached even from London, the route being by Stirling and Callander, and the duration of the journey from thirteen to fifteen hours. Dr. Baily has written a charming description, not only of the town with its immediate surroundings, but also of many picturesquely situated places of interest in the neighbourhood. The frontispiece is a view of Oban Bay crowded with yachts, as it often is in summer time, and numerous other landscapes are scattered throughout the pages. In conclusion, he recommends either the earlier months of the year or October as the best seasons for health-seekers and those whose time is at their own disposal to visit Oban; and he brings forward some strong evidence of its advantages even as a winter resort, on the ground mainly of the mildness and equability of the temperature and the profusion of plant life during winter. An average of ten years gave the mean daily temperature of January at Oban as 39·8° F. and of August as 57·3°, whilst at Torquay, in the south of England, the means for the same months were respectively 39·4° and 59 9°.

Fruits and Farinacea the Proper Food of Man. By JOHN SMITH. London: The Ideal Publishing Union. 1897. Pp. 172.—This is a new edition of a tolerably well-known vegetarian work, which was first published many years ago, and is, in the words of the sub-title, "an attempt to prove, from history, anatomy, physiology, and chemistry, that the original, natural, and best diet of man is derived from the vegetable kingdom." The author, evidently possessing considerable literary ability and not carried away by prejudice, availed himself freely of extracts from medical books which could be used in support of his case, but his reasoning almost necessarily falls short of being conclusive, firstly, because the original food of man is of no practical consequence at the present day; secondly, because the human alimentary tract does not correspond to that of either the herbivora or the carnivora among the lower animals; and, thirdly, because the most important vegetable food products are derived from cereals, all of which are unfit for use in the "natural" state, and require processes of preparation quite as complicated as those necessary for animal food. The best chapter in the book is probably the one headed "Vegetable Food Consistent with Physical Strength and Activity." In questions of this kind practical experience is more useful than theorising, and there is plenty of evidence that many persons find vegetarian dishes, when properly cooked, to be both wholesome and palatable.

A Handbook of Surface Anatomy and Landmarks. By BERTRAM C. A. WINDLE, D.Sc., M.D. Dub., Professor of Anatomy in Mason College, Birmingham. Second edition, revised and enlarged, in collaboration with T. MANNERS-SMITH, M.A., M.R.C.S., Lecturer on Osteology and Senior Demonstrator of Anatomy, Mason College, Birmingham. London: H. K. Lewis. 1896. Pp. 143. Price 3*s.* 6*d.*—We are told in the preface that this little book is not intended to be a treatise on surgical applied anatomy, but is meant for students of anatomy in their first and second years, to serve as a guide for that portion of the knowledge of the human body which can be gained without dissection. Directions are also given for the examination of certain of the orifices, and for the use of some of the common surgical instruments, such as the catheter. That the book has reached a second edition is proof that it has been found to be of value, but we should certainly be inclined to recommend it rather to students after they had entered the wards of a hospital than before passing in anatomy and physiology. It is, of course, desirable that while a student is studying anatomy he should have some idea of the various applications of this anatomical knowledge in the practice of medicine and surgery; and, indeed, most works on practical anatomy, such as "Ellis's Dissections" or "Cunningham's Anatomy," contain chapters devoted to superficial anatomy and to other anatomical facts which are found by the student to be important later in his career. But this introduction of medical and surgical applications of anatomy into the ordinary text-books intended for the use of students of the first and second year can easily be overdone; and in this volume we continually meet with words and phrases which must be almost incomprehensible to the student who has not yet entered on the study of surgery. The book is carefully written, perfectly trustworthy, and it is well illustrated by a large number of diagrams. We may especially commend the chapter devoted to a description of the relations of the scalp and skull to the fissures and convolutions of the brain; this section has been largely re-written for this edition. We consider that the book forms an excellent guide to the superficial anatomy of the body, and that, though it may assist junior students, it will be especially useful to candidates for the final examinations.

Analytical Records
FROM
THE LANCET LABORATORY.

XEROFORM.

(BURGOYNE, BURBIDGES, AND CO., 12 AND 16, COLEMAN-STREET, E.C.)

"XEROFORM" is a yellow powder, not unlike iodoform in appearance, and possessing a similar but less pronounced smell. It is a compound of tri-bromo-phenol with oxide of bismuth, the two being together in nearly equal proportion. It is insoluble, practically tasteless, and non-irritating, and appears to act as an excellent antiseptic. Bacteriological experiments have shown that it possesses a very powerful germicidal effect upon the comma bacillus and other pathogenic organisms. Xeroform is stated to have been used in gynæcological practice with gratifying results and also in affections of the skin. It is described as "the iodoform of the future."

RONUK.

(RONUK, LIMITED, 83, UPPER THAMES-STREET, E.C.)

This is a brown mahogany-coloured paste described as a sanitary polish and cleanser suitable for renovating the surfaces of the floors of a sick chamber or of hospital wards. It possesses a pleasant aromatic smell, and readily produces an attractive polish on leather or flooring with a minimum of work.

(1) ICHTHYOL; (2) DUODENIN; AND (3) HYPNOTIC CO. PALATINOIDS.

(OPPENHEIMER, SON, AND CO., 14, WORSHIP-STREET, E.C.)

The convenience of administering insoluble and nauseous drugs in the form of palatinoids is again illustrated in some recent new additions to the list. These comprise palatinoids of ichthyol, containing 3 grains of the sulph.-ichthyolate of ammonium; of duodenin, containing 5 grains of the purified enzyme of the duodenal ducts; and a hypnotic combination of potassium bromide 4 grains, morphia $\frac{1}{12}$ grain, cannabis indica extract $\frac{1}{8}$ grain, and pulv. fol. byoscyami 1 grain. The last is an approved formula, while the previous substances are of well-known value.

NEW FORMULÆ (PARKE DAVIS & CO.).

(PARKE, DAVIS AND CO., DETROIT; LONDON AGENCY, 21, NORTH AUDLEY-STREET, GROSVENOR-SQUARE, W.)

Perhaps the most interesting preparation recently sent to us by this firm is the Plasma Nasal Tablet. It is designed so that when dissolved in two ounces of water a solution of the same density as blood serum is obtained. The calculated effect of this is to prevent diffusion of the solution through the mucous membrane, leading probably to engorgement and irritation. The tablets are composed of sodium chloride, sulphate, and phosphate, with definite quantities of the same potassium salts; to these is added a small quantity of menthol. The resulting solution when a single tablet is dissolved in two ounces of warm water would appear to be well adapted for washing out the nasal cavities. Taka diastase is now well known as a powerful amylolytic ferment obtained by cultivation upon a species of fungus. It is now combined with pepsin and pancreatin, thus making the preparation of decided and general value in certain forms of digestive failure.

NEW TOILET PREPARATIONS.

(BLONDEAU ET CIE, MAIDEN-CRESCENT, N.W.).

The preparations submitted to us were as follows:—Violette de Parme Soap, Bouquet Soap, Lait Vinolia, Triple Extrait, and Brown Vinolia Cosmetic. Each and all showed a standard of purity consistent with purposes for which they are intended. The soaps contained an excellent basis absolutely free from any excess of alkali. Lait Vinolia appears to be a fatty emulsion not unlike milk in appearance: Ether extracted an oil along with which was associated the delightfully fragrant essential oil of the rose. The Triple Extrait consisted evidently of a solution of otto of roses in spirit. We could trace no objectionable ingredients in any of the preparations described.

EXTRA OAT STOUT.

(MICHELL, GOODMAN, YOUNG, AND CO, STAMFORD-HILL, N.)

An important departure in the preparation of this fermented liquor is the employment of a definite quantity of oat. As a consequence the extractive matters are found to contain a higher proportion of nutritive material than would be the case if barley malt were alone employed. An increase occurs chiefly in the amount of nitrogenous principles, and of the valuable mineral constituent, phosphate of potassium. The resulting liquor is of a mild but somewhat full flavour and in ripe condition. Our analysis was as follows: extractives, 6·30 per cent.; mineral matter, 0·45 per cent.; alcohol, by weight 5·0 per cent., by volume 6·24 per cent., equal to proof spirit 10·94 per cent.; total acidity reckoned as acetic acid, 0 90 per cent. It is clear from these results that the preparation is one of merit and a nourishing article.

NURSERY BISCUITS.

(A. ROBB AND CO., 79, ST. MARTIN'S-LANE, W.C.)

These biscuits are evidently prepared with a due consideration of the special requirements of infants and invalids in the choice of an easily digestible farinaceous food. The biscuits are delicately crisp and well cooked. They are somewhat sweet and malty to the taste, containing an excellent proportion of soluble carbo-hydrate, notably dextrine, which, as is well known, is a valuable element of food for children and of easy assimilation.

LIGHT BITTER ALE.

(THE BECK BREWING CO., PRESCOT-STREET, LIVERPOOL.)

The analysis of this product was as follows: Total extractives, 2·35 per cent.; mineral matter, 0 11 per cent.; absolute alcohol, by weight 0·05 per cent., by volume 0 07 per cent., equal to proof spirit 0·12 per cent; total acidity reckoned as acetic acid, 0·25 per cent. It contained no preservatives. The ale is evidently a genuine infusion of hops and malt liquor, but with only a trace of alcohol. It is brilliant and sparkling, with good flavour, simulating the ordinary brewed and fermented article.

MEADOW SWEET CHEESE.

(THE MEADOW SWEET CHEESE CO., 5, RAINFORD-SQUARE, LIVERPOOL.)

Our analysis of this excellent dairy product was as follows; Water, 33·43 per cent.; fat, 30·41 per cent.; casein, 32 12 per cent.; mineral matter, 4·04 per cent., containing 1·20 parts salt. These results are very satisfactory, and fully bear out the statement that this cheese is "carefully made from the milk of selected dairies and enriched with cream." The sample we examined was contained in a jar upon which was marked the date at which the cheese was made and packed. Since, as we found, there are no objectionable preservatives used in its manufacture, while it contains, as will be seen, only a minimum of common salt, it does not keep for more than a week or ten days. The proportion of fat is a noteworthy feature in the analysis; and, moreover, on determining its melting point we found it to be 31° C., which is exactly that of genuine milk or butter fat. The sample which we examined possessed an excellent flavour, free from roughness, bitterness, or acidity. It is evidently cheese, and nothing but cheese, and that of first-class quality. This, we fear, is more than can be said of much of the stuff that is sold as cheese in the English market at the present time.

THE LANCET.

LONDON: SATURDAY, AUGUST 7, 1897.

THE members of the British Medical Association who hunger and thirst after medical science will this year have to repair to Canada for their satisfaction. Those who rather affect questions of a medico-political sort or such as bear on the constitution and duties of the Association have already had their meeting. It really seems as if the members of the Association were divisible into two such sects as the above. There are, of course, a few striking exceptions—men equally at home in the discussion of either set of subjects; but, as a rule, there is a sharp line of demarcation, and certain names appear in the one section which are conspicuously absent in the other, and *vice versâ*. Nor is the blame one-sided. It is easy to say that the great questions affecting deeply the interests of the profession, its constitution, its privileges, and its duties, are discussed year after year by the same limited group of speakers, who might be counted on the fingers. The fact, however, is not the fault of the members in question. The general meeting of the Association is open to all members, and all should take a decided part in its affairs and their administration and in its constitution. Even as an instrument for the promotion of medical science the Association will suffer if the great majority of its members take no part or lot in the discussion of its duties; and as an instrument for affecting public and Parliamentary opinion it will suffer great impairment if the leaders of the profession do not do their share in giving a tone of moderation and breadth to questions which cannot be settled without reference to public and Parliamentary support.

The business meetings of the Association, if we may judge from the numbers who vote, are attended by a mere fraction of the members. At the meetings held last week the questions discussed were of great importance, such as the functions of the Council, the constitution of the Association, the deference due respectively to a general meeting of members and to the views of the branches carefully ascertained, the Midwives Bill, or, to speak more accurately, the Obstetric Nurses Bill, indirectly the question whether the Association should undertake the work of Medical Defence, the case of Mr. R. B. ANDERSON, and the disciplinary function of the Association in the way of excommunication. It will not be denied that these questions involve the very judgment and reputation of the Association—even of the profession—and that errors of judgment in regard to them may not only involve the Association in discredit, but may be disastrous to the profession, yet they were determined by 150 or 160 members; and it occasionally happens in the Association that the gravest questions are settled by half that number. It cannot be wondered at that the Council are fain to refer such subjects to the branches for careful consideration and advice, and that the judgment of the branches is not always the same as that of a general meeting, which is often controlled by a handful of speakers who are apt to regard themselves as the Association. It would be personal to specify illustrations, but members of the Association will have no difficulty in supplying them. It is the more unnecessary as we seem to detect in the proceedings of the recent annual general meeting, with one or two exceptions, a greater spirit of responsibility and moderation than has often of late years been exhibited, and a greater disposition in different sections to believe that there is something in other views than their own.

Two very different incidents in the proceedings deserve a word of notice. The presentation of the gold medals will be generally approved. If an association does not emphasise such services as those of Mr. WHEELHOUSE and Sir WALTER FOSTER there must be something wrong in it. The award of the Stewart Prize to Dr. G. SIMS WOODHEAD and of the Middlemore Prize to Dr. ALEXANDER HILL GRIFFITH will be equally approved. The other incident was of a painful character—the expulsion of two practitioners from the membership of the Association for having accepted offices under the Government of South Australia in the General Hospital of Adelaide, vacated by the whole staff as a protest against the conduct of the Government. The members so removed had ample opportunities of defending themselves. We cannot wonder at the all but unanimity with which the Association acted in this matter. The profession must protect itself, and it would be simply lamentable if a great voluntary association were to be stricken with the same paralysis of discipline which seems to threaten the chartered and statutory authorities.

IN the Bradford district—the home of the wool-sorters' disease—another case of death from anthrax recently occurred, in time, it is to be hoped, to check the withdrawal of certain restrictions which, from time to time, have been placed on the sorting of wool. But whatever means be adopted in the sorting-room, there must necessarily, from the nature of the dust in which the anthrax spores are carried, be very great danger, at some point or other of the process, to those engaged in wool-sorting or, as Dr. BELL, of Bradford, points out, in the removal of the dust from the vessel in which it accumulates. It appears that the time for the general consideration of the carriage of infective material in hides, hair, and rags has arrived; and although the destruction of none of the pathogenic organisms with which we are at present acquainted presents quite the same difficulties as are associated with the destruction of anthrax spores, there can be little doubt that the question of sterilisation in bulk is one that will have to be faced sooner or later.

As has been pointed out by the Dangerous Trades Committee of the Home Office, there are certain districts—notably Asiatic Turkey, Persia, Cashmere, South Africa, and Peru—from which fleeces from animals that have died from anthrax—fallen fleeces—are constantly being sent, whilst hides from some of these places and from China, and hair from Russia and Siberia, are often taken from

Digitized by Google

cattle and horses that have succumbed to anthrax. It is, of course, evident that the ideal method of treating such material would be by sterilisation before the goods are baled; but that being out of the question, it is all-important that some plan of sterilising in bulk, if possible, or in loosened bulk, if necessary, should be devised. In the case of hair, through which steam and liquids percolate most readily, the difficulty should not be very great, but in the case of pressed wool and baled hides the obstacles to thorough disinfection are necessarily very much greater. A dense mass of wool exposed to superheated steam, even for a very considerable period, could be affected on the surface only, whilst such treatment of leather would ruin it for all commercial purposes. We cannot think, however, that a committee, composed of practical men accustomed to deal with these various goods, of one or two thoroughly capable medical officers of health, and of a similar number of expert bacteriologists, would be unable to draw up a satisfactory report on the various means of dealing with goods coming from scheduled districts. Any one of these sets of men alone would be utterly incapable of dealing with the subject; but the whole of them, looking at the question from various points of view and with the benefit of each other's advice, should be able to draw up a workable scheme which would approve itself to all concerned. If the question could be settled as regards anthrax it would be settled for every other disease from which we have anything to fear from the carriage of infection through the agency of imported goods. In a letter published in our columns last week it is pointed out that if certain observations as to the persistence of vitality of the rinderpest virus be correct, it is essential that the hides from "dangerous" districts should be submitted to a process of disinfection before they are admitted to this country. Any measures that would be sufficient for the sterilisation of the anthrax hides would be, of course, more than sufficient for the sterilisation of rinderpest hides; but at present there are no methods known by which even baled rinderpest hides could be rendered free from the virus if it were present.

As regards the possibility of the carriage of the infection of plague to this country, considerable light has been thrown on the question by the various recent workers at the life-history of the plague bacillus. All are agreed that, except under very favourable conditions, the plague bacillus very rapidly dies out, whilst even under the most favourable conditions it is difficult, without constant re-inoculation and passage through living animals or human beings, for the organism to maintain a high degree of virulence. It follows therefore that wherever a long voyage has to be made, even in these days of rapid transit, the bacillus as a rule dies a natural death, and although the organism may be present and alive in goods that leave Bombay, it has lost its virulence, and usually also all vitality, by the time that it reaches—this country, say. Quite recently Dr. KOCH and the Bombay Commission have fully confirmed these statements as to the short life of the plague bacillus. Still, it is obvious that under certain conditions it might be necessary to disinfect rags and flock from plague-stricken districts; but in most cases this could be done with comparative ease, owing to the nature of the fabrics in which the infective material might possibly be lodged. This whole question is one of very great importance. It has even been suggested by the Dangerous Trades Committee that "Government should be empowered to stop the landing of hides on receipt of information that they come from infected areas." They also suggest that horsehair and bristles from Russian and Siberian animals should be excluded from our ports on the same grounds that infected animals are not allowed to be sent into the country. As we have already pointed out, no evidence can be collected that there is any danger of the conveyance of the plague to the United Kingdom through the wool that arrives from ports where plague is prevalent, and in this case the experience of those engaged in following the history of outbreaks of disease is entirely at one with the most recent scientific evidence. In the same way we have as yet no evidence that the rinderpest virus can be carried and remain active for any length of time in baled goods; even the laboratory experiments concerning the vitality and virulence of rinderpest virus do not afford grounds for definitely supporting this opinion, and anything that has been advanced has been in the form of suggestion rather than of actual statement. In the case of anthrax, however, we are dealing with a very different state of affairs. Owing to the conditions under which the anthrax organism finds its way into the wool and hair of animals that have died from anthrax, spores are almost invariably formed before the organism dies. These spores are extremely resistant to drying and, in fact, to all agents and agencies which might prove fatal to less resistant organisms. Their powers remain dormant apparently for years, and only come into play—but then with all their original intensity and virulence—when the conditions of moisture and nutrition are again sufficiently favourable for the development of the potential energy of the spore. This very fact renders it exceedingly difficult to sterilise any substances into which these organisms have found their way; but there can be no doubt that it is our duty to find some means by which these organisms may be rendered harmless before the fleeces or the skins come into the hands of the wool-sorters and the leather-dressers.

WE shall continue next week our Commissioner's report on hospital abuse at Birmingham, and take this opportunity of thanking our many supporters who have borne witness in public and private to the value that this branch of our work has in their eyes, and of assuring them that our policy in the past with regard to this important question will be our policy in the future. We shall continue in these articles to report facts obtained from trustworthy sources, or founded upon the personal investigation of our Commissioner, and we shall attempt to draw a moral from these facts that, haply, order may spring out of chaos, and a problem, or a series of problems, which now defies the remedial measures of all experts in charitable matters, may become simpler of solution in the light of more accurate special knowledge. Remedies academic or comprehensive will probably suggest themselves by comparison of the different troubles in different localities—but the first thing is to get the facts.

Digitized by Google

In this connexion we have pleasure in calling attention to Dr. ROBERT SAUNDBY'S letter upon our Commissioner's first article dealing with hospital abuse in Birmingham, which appeared in THE LANCET of July 31st. Dr. SAUNDBY'S letter will be found upon page 331 of our present issue. Dr. SAUNDBY'S name is probably known to many of our readers as President of the Council of the British Medical Association, and he is described in the Medical Directory of 1897 as Physician to the Birmingham General Hospital, Consulting Physician to the Birmingham Eye Hospital, Consulting Physician to the Birmingham and Midland Hospital for Women, and Examiner in Medicine to the English Conjoint Board — among other titles to respect. So that from more than one point of view we might have anticipated thoughtful criticism of our work from him. We might have credited him, as a pluralist in hospital appointments, with being aware that the efficiency of the hospital work of the kingdom has been much crippled by the distribution of indiscriminate charity, especially in the out-patient departments. We might, again, have felt secure that we should find him, as a high officer in the British Medical Association, quick to comprehend all sides of a topic the settlement of the inherent difficulties of which is a matter of such urgent importance to the general practitioner. In each capacity—whether as one of the chief officials of the British Medical Association or as a physician prominent in public charitable work—we might have fairly concluded that we should obtain from Dr. SAUNDBY a judgment of our work inspired by fairness as well as by special knowledge. Moreover, we might have expected from a gentleman who has held such responsible posts in the profession and who is a physician of experience and culture the usual courtesies of debate. Instead of which we receive the little letter to which we have already referred. In this letter we read of our Commissioner as a "self-sufficient gentleman," while lower down the eye catches the polite phrases, "spiteful misrepresentation," "cowardly and cruel libel," "suffering from the effects of the dog-days," "monstrous accusation," "interference of outsiders"—to cull a few blossoms, surely already a little faded, from Dr. SAUNDBY'S epistolary rhetoric. Not one word of justification does Dr. SAUNDBY condescend to employ. Our Commissioner has written, as he will continue to write, in full detail of the situation in Birmingham. On no point or points whatever does Dr. SAUNDBY controvert his statements. In not one single instance does he exhibit and gibbet the cowardice, cruelty, and misrepresentation of which he writes. He prefers to be vague and abusive, for we can use no other word to cover the phraseology we have quoted.

And here we might fairly leave the matter, for Dr. SAUNDBY has shown himself to be so unable to form an unbiased judgment of our aims that we might hold his estimate of our work valueless. We might respond that he was at liberty to think what he liked and say what he liked, but that we should be unable to afford him the gratification of taking him seriously. But we consider it important to dwell upon one point in Dr. SAUNDBY'S letter. We are bound to reflect that the myopia which Dr. SAUNDBY has exhibited, although in the enjoyment of unexceptional opportunities for insight into the difficulties that surround the question of hospital abuse, may be shared by others of our readers less fortunately placed. Therefore, we invite all readers of THE LANCET to peruse Dr. SAUNDBY'S letter and to note in it the untenable position of privacy from discussion that is there assumed for affairs that are clearly of public interest. Dr. SAUNDBY talks of "interference of outsiders," and reports certain of the profession at Birmingham as having told our Commissioner "to mind his own business." Our Commissioner, who gives us a truer view than Dr. SAUNDBY of the kindness and good sense of the practitioners in Birmingham, was minding his business—i.e., THE LANCET'S business—when he made his inquiries into a matter of the first interest to the medical profession. It is imperative that all should understand that the hospitals do not belong to the medical staff. It is imperative that the medical profession should realise that public charities must be administered for the public good, and that public deeds are open to public criticism. At the present moment the suffering poor, the charitable public, and the general practitioners alike suffer from the lax methods of the distribution of hospital benefits. As good men, as just citizens, and as kindly fellow practitioners, all medical men should do their utmost to help in arriving at better methods, if better methods can be devised. As medical journalists we have our share in this work, and we shall continue to discharge our duty as seems proper to ourselves, secure in our knowledge that what we have done has borne good fruit, and deeply conscious that had not it been for the hearty coöperation of the medical profession in so many localities the information which we have already been able to diffuse could not have been obtained.

Annotations.

"Ne quid nimis."

A PLEA FOR A STATE MEDICAL SERVICE.

IN a recently published pamphlet Dr. James Erskine, lecturer on Aural Surgery in Anderson's College Medical School, Glasgow, advocates a complete departure from the system of medical practice as at present constituted. The multiplication of hospitals, the gratuitous treatment of infectious disease at the public expense, the growth of the provident society organisations, and even the recent improvements in the practical parts of medicine and surgery, whereby methods have been introduced more and more difficult to apply in private dwelling-houses with the assistance of an amateur nurse, have all of them had the effect of seriously encroaching on the field of the time-honoured family medical man. Dr. Erskine puts the case accurately in describing this unsatisfactory condition of things as "an undeserved Nemesis overtaking the medical profession for their beneficent labour," and he does not hold out any prospect of an improvement under present conditions. His remedy is a nationalisation scheme, most of the details of which he leaves to be supplied by others, his main recommendation being that "hospitals ought to be uniformly free and accessible both as regards illness and locality." For some years the hospital question has, he says, been discussed mainly from the point of view of so-called abuse by patients in a position to

Digitized by Google

pay fees, and for various reasons he thinks that any agitation for reform on that ground is destined to fail, for the complaints being prompted by financial and professional considerations do not excite popular sympathy, and have not elicited any favourable response from the medical staffs or the governors of hospitals. In a State-organised medical service, however, this divergence of interests would not exist. "The hospital, as we have it at present, should be the great central institution of health ..... Medical laboratories would be provided at hospitals convenient for pathological work, and for original research and scientific investigation, in which men could work under certain regulations and with defined terms of encouragement and reward. Appointments would be made mainly by examination, repeated at intervals of years, and promoted by length and merit of service. Men in the national service would not be entitled to undertake any private practice for remuneration. If after serving the State a certain term they desired to practise among the wealthy or the class of the community declining to avail themselves of the national medical provision, they would be free to do so after relinquishing national appointments." ..... "A system of national hospitals must necessarily include medical schools." Such are the essential features of Dr. Erskine's scheme. The first observation which occurs to us with regard to it is that it would be practically an extension of the existing system of Poor-law medical relief with the hospital out-patient department superadded, and that it would have a disastrous effect on the development of medical science, for the incentives to individual effort would no longer exist and medical education would tend to become a mere perfunctory routine. Fashionable practitioners, unhampered by official trammels, would no doubt thrive as they have always done, but the appointments at the great hospitals would cease to be regarded as stepping-stones to fame and fortune, mediocrities would gravitate towards them, the spirit of progress would languish, and the best interests of the profession would suffer not a little by the change.

THE POONA OUTRAGES.

THE vindication of the authorities at Bombay and of the British soldiers employed on plague duty from the foul and scandalous charges brought against them is as complete as we, in common with most people, felt it would be. On all sides it is now admitted that these charges were false and unfounded. Professor Gokhale has been compelled to withdraw his statements and apologise for having made them. Sir William Wedderburn has taken the only course open to him and has expressed to the House of Commons his extreme regret for having directly or indirectly aided in giving currency to charges that cannot be substantiated; and a large and influential meeting of Mahommedans at Poona has freely admitted that there was no cause whatever for complaining of the proceedings of the plague committee, which had been carried out with the least possible inconvenience to religious feeling. We have now learned, too, the details connected with the murders of Lieutenant Ayerst and Mr. Rand, and these tend to show that they were the result of an organised plot, probably of a more or less political kind, and that the application of restrictive measures adopted for the suppression of the plague was rather the occasion than the cause of these crimes. Surgeon-Captain W. W. O. Beveridge, of the Army Medical Staff, who was engaged from first to last in attempting to check the progress of the plague at Poona and who was intimately acquainted with all the circumstances, does not hesitate to declare that "the charges made against British soldiers are absolute lies." This officer, whose life was probably aimed at, and not that of Lieutenant Ayerst, gives a most satisfactory explanation of British soldiers having been employed in plague work in preference to native soldiers, and he speaks in the highest terms of their bravery and devotion and of the intelligence, patience, and kindness they displayed in all their dealings with the natives. As our readers are aware, we from the first entirely discredited the scandalous charges that had been made, but it is satisfactory to be assured on the most unimpeachable evidence that they are false and malicious. The organisation and mixed composition of the search committees rendered it nearly impossible that such outrages should have occurred. Unfortunately, they were nevertheless accepted on mere hearsay by some persons in this country with most mischievous results and grave injustice to those responsible for our rule in India. Apologies, however full, cannot unfortunately efface these results; the mischief has meanwhile been done, and there will always be some evil-disposed or credulous people ready to believe such reports, in spite of all subsequent contradictions. It was Lord Melbourne, we believe, who remarked that if India were lost to this country it would be by the House of Commons. It is fortunate that the present Viceroy of India and the Governor of Bombay, who have been compelled by the force of the circumstances in which they have found themselves to have recourse to a system of criminal prosecution in support of law and order in India, should have received their appointments at the hands of the late, and not the present, Government, for it is an additional proof of conviction on their parts as to the necessity for acting as they are doing.

THE PETROLEUM HAIR-WASH FATALITY.

THE recent lamentable accident to Mrs. Samuelson has, naturally enough, excited not only widespread sympathy, but is one possessing features of unusual interest, from the point of view of scientific men, as to its *causa causans*, and also from the point of view of those upon whom the duty lies of safeguarding public health, using the term in its widest sense. Despite the verdict of the jury, "That the deceased died from the effect of burning caused by the ignition of petroleum, but how this ignited there was no evidence to show," we think it almost certain that the petroleum, or, to be more accurate, the petroleum spirit, was fired by an electric spark generated from the hair to the hands by friction. That friction of dry hair will generate such sparks is well known, and that such sparks will ignite explosive gases is also well known, as was lucidly set forth by Lord Kelvin in his letter to *The Times* of Aug. 2nd. It seems fairly certain that there was no actual flame in the room where the hair washing took place, but it is possible that the vapour travelled some distance and coming into contact with a distant light flashed back. But on the whole we think the electric spark theory is the more probable, especially as similar conflagrations often happen during the "dry cleaning process" of woollen and other goods. As to the responsibility of the hairdressers we shall say nothing, for the London County Council has, we are glad to see, issued a notice calling attention to the matter, and proceedings are pending as to the legality or otherwise of the use of petroleum spirit. The point to which we do, however, wish to draw special attention is the evidence of the Chief of the Public Control Department of the London County Council, who is reported as saying that "he had visited thirty-eight of the leading hairdressers of London with reference to the application of petroleum hair-wash. He found that twenty-five never used it; thirteen did use it, these being all French establishments; ten had given it up since this accident; three had not done so, and two of these stated that *since the accident there had been a greatly increased demand for petroleum hair-wash.*" (The italics are ours.) Fashion is an inexorable goddess, and we suppose that nothing on earth will make a certain class

Digitized by Google

of woman give up using anything which may perhaps enhance her beauty. Ignorance may be an excuse for those who used this preparation before the latest misfortune, although at least two deaths were reported from the use of it in a room with a naked light; but ignorance will not serve now, and yet we have the above startling evidence. As in Casimir de la Vigne's poem, it is a case of "On disait 'Pauvre Constance,'" and that is all, and the fashionable world goes on, if not dancing, using all sorts of quack or patent remedies merely because they are fashionable. An occurrence such as this is one more reason for the law as to patent medicines and other preparations being altered. The formula of all these nostrums should be stated on the bottle or package in which they are contained, and meantime we might state that an alcoholic solution of ammonia is quite as efficacious for the cleansing of hair as light petroleum oils, and is not fraught with danger like them.

THE IMMEDIATE REDUCTION OF THE DEFORMITY IN POTT'S DISEASE.

ON July 24th, at the Royal Southern Hospital, Liverpool, Mr. Robert Jones and Mr. A. H. Tubby demonstrated on a series of cases of Pott's disease the manipulations for immediate reduction of deformity. The children's ages varied from three to eight years, and some of the curvatures were very extreme. The deformities were reduced with considerable facility. The forced reduction of the deformity in caries of the spine has been advocated at various times,[1] but it has always met with much opposition. Recently the practice has been revived by Dr. Calot, of Berck-sur-Mer, who had employed it in thirty-seven cases when he wrote his paper.[2] He claimed that the healing process was much accelerated, and that most cases recovered under ten months. The method employed is as follows: forcible traction is made on the upper and lower parts of the spinal column, while firm pressure is exerted over the prominence. When the deformity is reduced a plaster jacket is put on. We believe that the cases mentioned above are the first that have been treated by Calot's method in this country. An exact estimate of the value of the treatment is impossible at the present time.

HOUSE AGENTS AND RENT COLLECTORS AS SANITARY INSPECTORS.

THE sanitary authority of St. James's, Westminster, has made it a condition for the appointment of sanitary inspector that he shall not deal in house property or act as a rent collector or an agent for absentee property in that district. The authority is to be congratulated on this determination, as it is clearly a difficult matter, with human nature constituted as it is at present, for an officer interested in house property to view that property in an altogether unbiased fashion, or, in cases where he has to collect the rent, to order such reconstruction of drains, &c., as will render it a difficult matter to obtain the rent in question. Dr. J. Edmunds, the medical officer of St. James's, Westminster, thinks that a restriction of this nature might well find a place among the regulations of the Local Government Board which appertain to sanitary inspectors, and there is certainly much to be said for the proposal. We have ourselves seen instances where sanitary inspectors who acted also as house agents found great difficulty—that is, if the state of the houses in which they were interested can be taken as an index—in carrying out their duties as inspectors. If, however, we are to reduce this position to its logical conclusion it will be necessary for Parliamentary powers to be obtained to prevent jerry-builders and all persons interested in businesses leading to air and water pollution from occupying seats on district councils. It is the presence of such men as these which prevents the adoption of proper by-laws, the removal of the smoke which envelops our manufacturing towns, and the cleansing of the water courses which traverse them. At the same time, we fully admit that it is the existence of enterprising men, such as large manufacturers frequently are, which contributes in no small degree to our national greatness.

THE CHURCH SANITARY ASSOCIATION.

THE annual sermon of the Church Sanitary Association was preached on Aug. 1st ("Sanitation Sunday") in All Saints' Church, Tufnell Park, London, by the vicar, the Rev. W. J. Hocking. The preacher took for his text the motto of the association, "I will, be thou clean" (St. Mark i. 41), and in the course of his sermon said that two things were beginning to be learned by slow degrees: first, that diseases and pains were not necessarily parts of the economy of human life, but the consequences of imperfect conditions; and secondly, that nine-tenths of the physical ills, diseases, and deformities from which men suffer were traceable to the violation of wise and beneficent laws, and hence were preventable. Science was making it clearer and clearer every day that not only diseases, but a very large proportion of deaths, were attributable to causes evolved out of conditions for which men were, directly or indirectly, responsible. Mr. Hocking also said that it was one of the phases of the Church's mission in every parish to be the teacher of everything that makes for the health of the community—"as well for the body as the soul." Sermons upon the same subject were preached in various parts of the country, the Gospel for the day indicating that concern for the temporal welfare of the people was part of the duty of the Christian ministry. In thus impressing on the masses a sense of the necessity of attending to domestic and personal hygiene the clergy have before them a wide field of usefulness, in which it is possible to benefit their congregations without any excursions into questions of therapeutics. The special feature of the Gospel for last Sunday was the miracle of feeding 4000 persons in the wilderness.

OPERATION FOR HYDATID TUMOUR OF THE SPINAL CORD.

IN a recent number of the *Inter colonial Medical Journal of Australasia* Dr. Jeffreys Wood records a case of very great interest. The patient was a child, aged ten years, without anything significant in his personal history until, at six years of age, he began to wake at night complaining of pain in the back. During the day no pain was complained of. In September, 1893, there was loss of power in the right hand and arm, but this gradually passed away, so that he was able once more to use the hand for writing and with a knife to cut up his food. During 1894 and 1895 the patient remained well and fairly active. About Christmas of the latter year he was noticed to drag the feet in walking. The difficulty in walking increased in the early months of 1896, and in March of that year pain in the left arm was complained of, in addition to the pain in the back and in the right arm, which had been frequent during the previous two years. The left arm also began to waste and the difficulty in walking increased, so that from the commencement of April, 1896, until his admission to the Children's Hospital in May of the same year he was kept in bed, being unable to stand. During this time he lost all power over his legs, bladder, and rectum, and priapism was very troublesome. The pain in the back and arms also increased. On admission to hospital he was found to be a

Digitized by Google

bright, intelligent boy, with complete motor palsy of the legs, exaggerated knee-jerks, and ankle clonus on both sides. Both arms were much wasted, and the head was drawn towards the left shoulder, and there was inability to turn it to the right. There was complete loss of cutaneous sensibility up to the level of the second rib and there was also anæsthesia over the inner side of each arm. There was ability to flex both arms at the elbow, but extension at the elbow could not be carried out. There was drop-wrist, the fingers were flexed at the mid-phalangeal joint and could not be voluntarily moved. The thenar and hypothenar muscles were wasted, more on the right side than on the left, and the muscles of the right hand did not react to Faradaism; those of the left hand did. The triceps and deltoid on each side showed the reaction of degeneration, and the symptoms were taken to indicate some gradually increasing pressure between the level of the nucleus of the fifth cervical nerve and that of the sixth. The spine was trephined at the level of the fifth cervical spine and the laminæ of this vertebra and of that below it removed with forceps. The cord was seen to fill the canal, and there was no pulsation. A swelling was seen on the right side of the cord. In separating the dura mater from this it was seen to be a hydatid cyst, and on opening it a small amount of hydatid fluid escaped and a number of daughter cysts quickly followed. Considerable difficulty was experienced in getting rid of the daughter cysts, but in all sixteen were removed, together with the mother cyst. After the operation there was a considerable degree of recovery of voluntary power for a short time, but unfortunately symptoms of cerebral meningitis developed, and the boy died eighteen days after the operation. The unfortunate termination of a case so admirably studied and carefully operated upon is much to be regretted.

MEDICINE FOR THE MIND.

LADY MACBETH'S medical attendant was obliged to confess his inability to minister to a mind diseased, but according to the modern school of psycho-neurologists the cleansing of psychically affected brains is by no means beyond the range of medical achievement. In a work which has just been published[1] M. de Fleury combats with great seriousness the old-fashioned hypothesis that bodily ills alone are the province of the practitioner. The disorders of the psychic half of the human economy are every whit as numerous and important, if not more so, than those affecting the somatic half, and everyone reflecting on the havoc they occasion must acknowledge that systematic efforts should be made to render them amenable to treatment. Laziness, grief, and anger are among the mental affections discussed by the writer, not only from a curative, but also from a prophylactic, point of view, but his remarks should be perused in the original. As might perhaps be expected, an entire chapter is devoted to the tender passion under the heading, *La Médecine des Passions*. "Love," says M. de Fleury, "is a physiological phenomenon which enters the domain of pathology the moment it assumes the sentimental form. Do we not habitually say, 'So-and-so is madly in love'? This passion, which is beyond the control of sense, in face of which reason loses her rights and her powers, is incontestably a human malady." The symptoms of *l'Amour-Maladie*, we are further told, bear a wonderful resemblance to those of alcoholism and morphinomania. Everyone who inquires into the facts for himself will be struck with the absolute identity of the pathological processes in each case. The point of departure is different, but the results are precisely similar, and the same treatment—namely, separation—cures both. M. de Fleury's theories are ingenious, but it cannot as yet be said that he has discovered the sweet oblivious antidote which Shakespeare's Thane asked for; nor, for the matter of that, a panacea of any kind for thick-coming fancies.

[1] L'Introduction à la Médecine de l'Esprit. Paris: Alcan, 1897.

THE AUSTRALIAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE seventh session of the above association will commence on Jan. 6th, 1898, the place of meeting being Sydney. The objects of the association are to give a stronger impulse and a more systematic direction to scientific inquiry; to promote the intercourse of those who cultivate science in different parts of the Australasian colonies and in other countries; to obtain more general attention to the objects of science, and a removal of any disadvantages of a public kind which may impede its progress. The president-elect, who also holds the office of permanent honorary secretary, is Professor A. Liversidge, M.A., LL.D., F.R.S., who will answer any questions addressed to him as to proceedings, &c., and will furnish a list of hotels, apartments, or boarding houses, with tariffs, to members of the association. Inquirers are particularly requested to state the nature and amount of accommodation they may require. The sections into which the subjects for discussion are divided include nearly every department of science other than medical. The steamship and railway companies give reductions in fares to members upon production of their cards of membership. Besides the general meetings, excursions will be organised to various places of interest in the neighbourhood, and this portion of the Congress will no doubt be by no means the least appreciated of the proceedings, for the scenery of the Blue Mountains is as beautiful as any in the world.

TYPHUS FEVER IN LIVERPOOL DURING 1896.

IN these days we hear but little of typhus fever in England, and it will probably be a matter of surprise to many persons to learn that during 1896 there were in Liverpool as many as 305 cases, with 36 deaths, of this disease, as against 162, with 24 deaths, in the previous year—figures which go to show that although this disease was more prevalent in Liverpool during 1896 than during 1895 the fatality rate was lower. The latter fact may be partly accounted for by the circumstance that during 1896 one of the day industrial schools appears to have acted as a centre for disseminating the disease, and that thus the age distribution of the attacks was a favourable one. Dr. Hope tells us that the greater number of the attacks occurred in the south end of the city, in parts notable for "drunkenness, squalour, and filth," circumstances which are almost always found to be associated with this terrible disease. Upon the discovery of a case of typhus fever in Liverpool the patient is at once sent to the isolation hospital and the infected bedding and clothing are destroyed. Furthermore, an inspector visits the house from which the patient is removed every day for a fortnight, and makes minute inquiries as to any other suspicious cases of illness, while regard is also had to all persons who may have visited the house prior to the removal of the patient and the disinfection of his belongings. Notwithstanding these precautions, Dr. Hope remarks that the disease at times remains unrecognised until a localised outbreak attracts attention. As he observes, typhus fever is by no means easy of diagnosis even by persons fairly familiar with its manifestations, and it is obvious that, owing to the rarity of the disease, especially in London, the majority of the younger generation of medical practitioners must have passed through their hospital experience without seeing a case at all. We are accustomed to flatter ourselves that we have practically "stamped out" typhus fever from our

Supplement to THE LANCET, August 7, 1897.

The Twelfth International Medical Congress.

(MOSCOW, 1897.)

MEDICINE. PAST AND PRESENT, IN RUSSIA.

I.

Introductory.

MOSCOW will shortly be the scene of an International Medical Congress, the twelfth of those great meetings which are successively held in different countries, and which will now gather for the first time on Russian soil. With Russia for the time being the centre of the medical world it seemed not unlikely that a description of some of her medical institutions would prove as interesting as it could not fail to prove instructive. It was with the object of describing these as they now are in the present year of grace that the following articles had their inception. It soon, however, became clear that the existing condition of medical institutions in this most interesting of countries could only be properly understood by treating them historically and tracing them up from their earliest origins to their present state of advanced development. The original scheme of the articles had in consequence to be much expanded. But, as though in compensation, a large number of facts and incidents in the history of medicine in Russia were brought to light in the course of this investigation into the little known records of the past, which cannot, we believe, but prove of real interest to English members of the profession and, more particularly, to those who intend to take part in the Congress in Moscow. These alone appeared to justify the more expanded treatment of the subject.

To Englishmen there are, indeed, many striking features in this history. Firstly, English medical men have played a not unimportant part in the introduction and improvement of the medical arts in Russia. Among the foreign medical graduates who have from time to time entered the Czar's service our own countrymen have always held a leading, and at one time held quite the first, position. It seems but right at the present moment that the names of these half-forgotten worthies should be resuscitated from the English and Russian records of their times; that their interesting and, in some instances, historically important experiences should again be briefly told; and that due prominence should be given to the generous treatment they invariably received from their Imperial patrons. Should the part played by Englishmen seem to be brought unduly forward in the following pages the excuse must be that this was almost inevitable in articles intended for English readers, and that no discourtesy is thereby implied to the memory of the many medical worthies of other nationalities who may have filled equally important positions, but whose stories are more briefly told.

A second striking fact in the history of medical institutions in Russia is one which is common to the history of almost all institutions in that country. No English historian of Russia has failed to notice the contrast between the growth of institutions in the two countries. With us they have usually originated in the initiative of private individuals or communities, who have only ultimately gained for them the recognition and approval of the State. In Russia this course of events has been usually reversed. There the Czar, as the *Batushka* or "little father" of his people, has in times past usually summoned from abroad cunning artificers, physicians, surgeons, and men of learning, and with their aid has planned and organised professional or other institutions, and trained the people to a recognition of their value and use. In one case the impetus has been from below upwards, in the other case from above downwards. Each method has had its advantages. Each course was, perhaps, inevitable from the history, geographical position, and national characteristics of the two peoples. And, so far at least as concerns the particular group of institutions which will here be considered, each has ended in providing the country with a series of such institutions and a private and public medical service of the nature best adapted to meet its needs. It is not intended here to compare the wants of the two countries or the way in which they are provided for; but it may be said in passing that few capitals in Europe can show a more perfect series of hospitals, laboratories, and other medico-scientific establishments than may be found in St. Petersburg and Moscow; in a word, nowhere are the needs of scientific medicine more fully recognised or more generously satisfied than in the Russian capitals. Of the truth of this statement visitors to the Congress will have ample opportunities of judging for themselves, for, with the courtesy characteristic of our Russian *confreres*, the medical institutions of both cities

Digitized by Google

will be thrown freely open to the inspection of all members of the Congress.

A no less interesting object of study than the provision for the medical wants of the capitals is presented in the country districts of Russia by the efforts of the *zemstvos*, or local administrative bodies, to provide the peasants with a system of free medical aid. Finally, there is the immense machinery of state medicine and the public health service forming a vast bureaucracy, with a Medical Council and Medical Department at the head, all of which present characteristics worthy of study. In this connexion attention may be called to the fact that the present Medical Department is a direct descendant, without a break, of the old Court *Apteka*, or Dispensary, which was probably first instituted by an English apothecary late in the sixteenth century.

The information upon which the following notes upon medicine, past and present, in Russia are based has been gathered from a variety of sources. The historical facts have been taken from contemporary records, both Russian and English, from historical works in both languages, and from numerous pamphlets and articles in Russian periodicals, to enumerate which would serve but little purpose. The light thus cast upon one of the by-paths of history, hitherto ignored by the general historian, appears to throw no little reflected light upon the broader and more trodden paths. The description of the medical institutions of to-day is based as far as possible upon actual observation and documentary evidence; but for much supplementary information it is our pleasant duty to express our sincere thanks to many of our Russian *confrères*; to Professors Klein, Erismann, Diakonof, Roth, Pospiélof, and Filatof of Moscow; to Professors Pashutin and Sklifosovski, and Dr. Ragozin of St. Petersburg; to Dr. Isaief and Dr. Dobrotvorski of Cronstadt; and finally to His Excellency Count Delyanof, the Minister of Public Instruction, and his secretaries, Messrs. Latyshef and Anitchkof, for details and statistics relating to the universities and medical education in Russia.

II.

The Earliest History of Medicine in Russia.

THE first chapter of the history of medicine in Russia opens at a period when—if the bull be permitted—medical science as such did not exist. Its germs were there, however. Even so early as the arrival of the more or less mythical Rurik, from which the history of modern Russia usually dates, its traces may be found. Such knowledge of the healing art as then existed was entirely in the hands of the *Koldunui* and *Volkhvui*, the *Kudesniki* and *Viédunui*—the wizards and wolf-men, the sorcerers and seers—grey-haired old men who wandered about in woods, who expounded the cult of the Pagan religion, who transmitted the ancient traditions and laws from generation to generation, and who were prophets, seers, chiromancers, and magicians. This was in the early centuries of the Christian era,[1] when the Russian country and race first appear in definite outline on the page of history. It is tempting to recur to a still earlier period, when Russia was inhabited by a race of whom scarcely an outline remains, if only for the fact that among the dim traces which time has spared of them is a record pointing clearly to their knowledge of the art of surgery. Of the Scythian race, their origin and history, comparatively little is known; but of their customs and arts much has been learned from the superb collection of Scythian relics recovered from the tombs of Kertch and southern Russia generally and now preserved in the Hermitage in St. Petersburg. In this collection, which consists for the most part of personal ornaments and vases of gold or other metal, is a small vase made of the combination of metals known as electrum. This beautiful little object was found in a tomb at Koul-Oba, and is generally known as the Koul-Oba vase. It is considered by experts to be of Greek workmanship, but the figures which it bears are purely Scythian. The vase is ornamented with three groups of figures in *repoussé*, and all three of these are of curious interest. (Fig. 2). In the first a Scythian chieftain is seated and listening to the advice of a kneeling figure, which has been conjectured to represent a *volkhva*, or "wolfman." This group may, therefore, in view of the character of the two others, without any great stretch of the imagination be regarded as representing an early Scythian medical consultation. In the second group a Scythian is examining with his fingers the teeth on the left side of the jaw of another, who appears to be the same chieftain as that

FIG. 1.

The Koul-Oba Vase.

represented in the first group. In the third the same two figures again recur, but in this instance the chieftain has evidently been wounded in the leg, which the surgeon is binding with a long bandage. Now, in examining the chieftain's skeleton found in the tomb from which this vase was taken a curious fact was brought to light. Two teeth in the left side of the jaw were wanting, and around the third, which was diseased, were signs of inflammation of the bone. In addition, the bones of the left leg are said to have shown traces of injury. It seems almost certain, then, that the incidents depicted on the vase were really important ones in the life of this forgotten Scythian chieftain. It were pleasant, did space permit, to linger on this interesting little relic, and to dwell upon the accuracy of detail and the vividness with which the actions are represented. It is the perfection of realism—a realism in no way destroying, but rather enhancing, the decorative effect.

The peculiar and unusual character of the groups just described has led to some speculation as to the purpose for which the vase they adorn was originally intended. That it was meant for some purpose more or less closely connected with medicine seems probable, and a suggestion has recently been made that it originally contained some poison. There is evidence that among the Scythians when a chieftain was buried his wife, his horse, and several slaves were buried alive with him in the same tomb. The Koul-Oba vase was found close to the remains of the chieftain's wife, and it has been thought that it may have contained a poison humanely put within her reach to enable her to put an end to

[1] Rurik is thought to have gone to Russia in 862.

Digitized by Google

her sufferings. This for the present remains an open question. Dr. Zmćief tried quite recently to throw some further light on the matter. He obtained some scrapings from the dried crust which lines the vase and submitted them to chemical and microscopic examination. He was able to determine that they contained neither opium nor arsenic, but apparently came to no positive conclusion as to their composition.

Nearly 1200 years elapse between the date of the Græco-Scythian relic found in the Koul-Oba tomb[2] and the time of Rurik. During the interval history is almost silent. On matters relating to medicine she is absolutely silent. It is only after the "Norman Conquest" of Russia, in the year 862 A.D., that the story again takes definite shape, and known historical characters begin to replace the more or less mythical heroes of the earlier period. As the mists clear away the warrior princes are naturally the first to take outline. But next to them there are no figures which become so clearly defined as those of the grey-haired sages already briefly described. Russian writers have loved to dwell upon them, to paint them as men of real dignity and sometimes of sublime independence—tall grey figures wandering in the untouched forest and culling simples on the banks of the Dnieper or the Bug, where doubtless they learned something of

> "the powerful grace that lies
> In herbs, plants, stones, and their true qualities."

Not infrequent references to them and their knowledge may be found in the *Builinui*, those interesting and (to Englishmen) too little known national epics, which sing the deeds of knights and heroes, real and mythical—of Vladimir the Great in his white-walled city of Kief and of his warriors ever seeking fresh adventures in the open field. In "Ilia Muromets"—the most popular of these epics—Ilia lies for thirty-three years in sloth and impotence, until the seers or wizards give him a honeyed drink. He drinks a "bucket and a half," and all his strength returns, and he is enabled to go into the arena and overcome the monster Solovei, whom he brings bound to his stirrup to the very courtyard of the Prince Vladimir's palace. It was a *kudesnik*, "beloved of the gods," who stopped King Oleg in a dark forest and foretold to him the strange manner of his death. The legend is told in one of Pushkin's best known poems. But it is needless to multiply instances; the "grey-haired *Koldoun*" is a familiar figure to all readers of Russian national literature.

In the tenth century Christianity was introduced into Russia. It came from Byzantium, and with it came such knowledge of medicine and the other arts as Byzantium then possessed. There, as elsewhere in Europe, the care of the sick was part of the duty of the monastic profession. The earliest Russian monastery was the famous Petcherskaia Lavra, or Monastery of the Caverns, in the newly-built capital of Kief. The earliest monks in Russia came direct from Mount Athos, where St. Athanasius had built a hospital for the sick. They carried with them the medical knowledge they had there gained, and the Petcherski monks soon became famous for their skill in treating disease. The names and reputation of a few individual monks are still preserved in the monastic chronicles. Anthony, a St. Athos monk, was considered a marvellous physician; Alimpi was reputed to cure leprosy by means of an ointment; Agapit, a pupil of Anthony, worked wonders with his *zelié* or simples, not only among his brethren, but among the laity. This last monk is the hero of an amusing tale of rivalry between himself and a lay "doctor," an Armenian, who settled in Kief, and there practised medicine with no little success. The layman treated the highest *boyars* and even the Prince Vsevolod himself. On one occasion he was summoned to attend the Prince's favourite *boyar*, but finding him apparently beyond recovery he declined further to treat him. He told him that he had but eight days to live. The *boyar* in despair sent for Agapit, who gave him his usual simples, and in the end the great man recovered and the monk was covered with glory. The Armenian was furious with jealousy and a very pretty quarrel began between the two practitioners. At last the Armenian hit upon a plan by which he hoped to ruin the other. He obtained a condemned criminal, gave him some poison, and sent him as a patient to Agapit in order that he might die before his eyes and in spite of his treatment. But the plot failed. The monk recognised that the man was poisoned, gave him some antidote, and saved his life, thus further increasing his reputation. The quarrel then became still more acute. The famous Prince Vladimir Monomakh (it was he who married Gytha, the daughter of our own Saxon King Harold) had been long treated by the Armenian without success. Again the monk stepped in and cured the patient by merely sending him his herbs! But at length Agapit

FIG. 2.

A Diagram representing the groups of figures on the Koul-Oba Vase. (Like Fig. 1, this illustration comes from a picture in Mr. A. Maskell's work "Handbook on Russian Art.")

[2] The vase is ascribed by experts to the fourth century B.C.

Digitized by Google

himself fell ill and was visited by his rival. A medical discussion began, and ended with the Armenian exclaiming contemptuously: "This man knows nothing of our art." He took the hand of the monk (perhaps to feel his pulse) and told him he would die in three days. "That is your way of treating disease, is it?" said the other. "You have more to say about death than about helping me. I tell you my death will not come in three days, but in three months." And so it did—a fact which seems to have so struck the Armenian that he at once joined the Church and became a monk in the same monastery. The story, with its series of triumphs of ecclesiastical over lay medicine, and its characteristic ending (it is told by a Petcherski monk), is of interest in more ways than one. Among other things it shows that in the eleventh century poisons and antidotes were known and used; and also as Professor Zagoskin (from whose book it is here quoted) rather quaintly remarks, "because it shows that even then methods of competition between rival practitioners were in vogue not in consonance with their high calling and with the demands of what we now call 'medical etiquette.'"

With the coming of Christianity and the Byzantine monks the fate of the ancient sages and wizards was sealed. The new Church entered into a fierce persecution of the whole race of *kudesniki* and their allies. They sent them to the gallows or the stake and pronounced the practice of magic or sorcery a crime against the true faith. In the Statute of Ecclesiastical Courts, published by Vladimir the Great, himself the first Russian ruler to be baptised, *zeliénitchestvo* is declared to be a specific crime, and as this term appears to have meant the use of *zelié* or simples, the clause was probably a blow aimed at the heathen professors of medicine generally. But the lay art did not die easily. The seers and the system they represented were too firmly rooted in the country and in the hearts of the people to be eradicated in a day. It may even be questioned whether they have ever become quite extinct. The "grey-haired *Koldoun*" may no longer exist as such, but in all essentials he is alive to this day. The *znakhar* and *znaknarka*, the "wise man" and "wise woman," to whom the Russian peasant still turns in cases of illness and misfortune, are the direct representatives of the ancient wizards and sages of the time of Vladimir. They are still believed to possess a mysterious power and skill in the healing of disease, and there is still a widespread faith in the superior virtues of their wonderful simples over all the drugs in the Pharmacopœia.

It will have been noticed from the story of Agapit and the Armenian that so early as the eleventh century a class of foreign practitioners was in existence in Russia. In that and the following centuries incidental mention is not infrequent of foreign physicians and their treatment. It has been conjectured that they came from Byzantium and possibly also from Arabia. These lay practitioners were of no little repute. They were to some extent opposed by the monks, but they were powerfully protected. The princes and *boyars* preferred their services to those of the monks, which they left to the lower classes. The monks always refused payment for their treatment, but the laymen were paid and apparently well paid. In the oldest code of Russian laws in existence—that of Yaroslav, compiled in 1018—a person wounded in an assault, in addition to receiving three *grivnas* compensation from his adversary, was entitled to one *grivna* for the practitioner's fee. A *grivna* was the third part of the price of a horse in those days. Of the nature of the medical practice at that time and of the remedies employed almost nothing is known. Surgical interference in certain cases was, it seems, sometimes resorted to. In 1076, two days after Christmas Day, Prince Sviatoslav[3] died from the "cutting of a tumour" or of some form of local induration or swelling. Very much later a certain Prince Dmitri was treated for bleeding at the nose by means of plugging the nostrils. Hospitals, or rather infirmaries for the disabled, were also in existence, and mention is made in 1091 of a bathing establishment in Pereyaslavl, though whether for medicinal or merely for cleansing purposes is not clear.

Early in the thirteenth century Russia was conquered by the Tatars, and during the next two and a half centuries of rapine and war there was of necessity almost complete cessation of the practice of the peaceful arts. Such medical art as there was at this period was entirely in the hands of the monks, who were generally spared by the Tatars. This miserable period came to an end in the time of Ivan the Third, whose reign from 1468 to 1505 is an important one in many ways. He was the first Russian ruler who took the title of Czar. He married the Byzantine princess Sophia Paleologos, and in her suite there came to Russia many refugees from the capital on the Bosphorus, which had only recently fallen into the hands of the Ottoman Turks. The result was a general revival in Russia of all the arts—a revival for which the overthrow of the Tatar supremacy had paved the way, and which was still further stimulated by the advent of the more cultured Byzantines. Among the arts which shared in the renascence was that of medicine. Foreign physicians were invited to settle in Moscow, which had long before become the capital, and several did so. Presumably some high inducement was held out to attract them; for to enter the service of the Russian autocrat of those days was to run no little personal risk. The fate of the first two foreign doctors who arrived in Moscow could scarcely have been encouraging to those who followed. Their histories are worth quoting briefly.

The first to enter the service of Ivan was one Anthony, a German, who came to Moscow in 1483. He was in high favour with the Prince, but even that could not save him. Only two years after his arrival he was ordered to treat a Tatar prince who was then in Moscow. He failed to cure him, and, in accordance with what seems to have been the pleasing custom of the age, was handed over to the relations of the dead prince to be dealt with at their will. The Tatars dragged him to the banks of the Moskva River, and there "cut his throat with a knife like a sheep!" Five years later Master Leo,[4] a Venetian Jew who with other artificers had been brought to Moscow through the Byzantines, was commanded to treat the son of the Grand Duke himself. He was rash enough to pledge his own life that the prince should recover. The patient had some affection of the legs; Leo gave him his simples and applied poultices and hot bottles, but with no avail. The disease got worse and the prince died. The unfortunate practitioner was thrown into prison, and six weeks later was publicly executed. The people considered his death a just one; he had deceived the Czar and had brought his fate on himself—a statement, it must be confessed, not without some element of truth. It was not always easy for those who had once entered the Czar's service to leave it. The murder of the German doctor, Anthony, created a panic among the other foreign craftsmen. Aristotle Fioraventi, the famous Venetian architect, designer of coins, caster of cannon and of bells, who rebuilt the beautiful Cathedral of the Assumption as it now stands in the Kremlin in Moscow (the same cathedral in which the present Czar was so recently crowned), when he learned of the murder, begged to be allowed to return to his own country. But his request so enraged the Grand Duke that he put the unfortunate man under arrest in his own house and confiscated all his goods.

[3] Professor Zagoskin by an obvious slip says Sviatopolk.

[4] The title of Master appears to have been usually applied to Jewish doctors in the Middle Ages, as they were excluded from bearing the title of "Doctor."

Digitized by Google

In the following reign, that of Vassili IV., a Russian subject named Theophil was taken prisoner in Lithuania and carried to Moscow. There he began to practise medicine, and with such success that when in 1516 the margrave in whose service he had formerly been demanded his return the Russian prince refused to let him go. To a like request two years later the prince answered: "He has many of the nobles on his hands under treatment; besides he has already a wife in Moscow." In this case the foreigner had, it seems, become quite at home in his new surroundings and did not himself wish to leave. Nineteen years later he was still in Moscow, for in 1537 he was ordered to make a medical examination of a certain princeling who had refused to enter the military service on the pretext of illness. Two other names stand out at that period, those of Marco, a Greek, and Nicolo, a native of Lübeck. The second is described by the imperial ambassador, who visited Moscow in 1518, as "Maestro Nicolo Lubacense, professor di medicina et di astrologia et di tutte le scienze fondatissimo." This professor of all fundamental knowledge treated the Grand Duke in his last illness, but of his other exploits almost nothing is known.

III.

The Reign of Ivan the Terrible.—Alien Physicians in Russia: their Diplomatic Positions.

WITH the accession to the throne of Ivan IV.,[5] better known as Ivan the Terrible, begins a period in the annals of Russian medicine of much greater interest to Englishmen than those hitherto described. The story of the relations between England and Russia in the middle of the sixteenth century has often been told, and it is not proposed to go over that well-trodden path again here. The voyages of Chancellor and Willoughby, the "discovery" of Archangel, the foundation of the Russia Company, the establishment of diplomatic and commercial relations between London and Moscow, and the abortive attempt of the Czar Ivan the Terrible to bring about a still closer union of the two countries by marrying an Englishwoman—all these are matters known to everyone who has the slightest acquaintance with the course of Russian history. What is not so generally known is that an important part in these events was taken by the English physicians or medical practitioners who were invited or sent to Moscow from London at that time. Many of the numerous letters which passed between the Czars Ivan and Feodor on the one hand, and the Queens Mary and Elizabeth on the other, are taken up with the important subject of the choice and despatch of a trusty body-physician for the service of the Russian autocrat. And the men who entered this service—one that was still not without its perils—were not only men of high professional attainments but were something more than physicians. In many cases they were trusted diplomatic agents who carried on important and delicate negotiations between the two countries. In those days, when there was no resident ambassador of the one Court at the other, but only occasional missions for some special purpose, it was obviously of great advantage to an English statesman to have an intelligent, educated, and observant person, such as a physician would be, residing at the Russian Court, and ready and able to keep him in touch with all that was passing there. Nor were the English statesmen of the time slow to take this advantage; not only in the case of physicians, such as Mark Ridley or Jacob, who were duly accredited from one Court to the other, but even in the case of those who entered the Russian service privately, such as the scoundrel Bomelius, whose story will be told presently.

The first Englishman who went to Russia to practise medicine appears to have been Dr. Ralph Standish. Unfortunately but little is known of his career. He had graduated M.D. at Cambridge in 1553, and had been licensed by the College of Physicians to practise for one year only in November, 1556. In 1557 he sailed for Russia with the famous Antony Jenkinson, the first English ambassador at the Muscovite Court. He reached Moscow, but of his experiences there and his ultimate fate no traces are left. Contemporary with him was a certain Italian practitioner, named Arnolfo Linsœus, who appears for one moment only on the page of history. He was summoned to attend the victim of one of the Czar's jests. Ivan had given one of his boon companions, a Prince Gvozdef, some scalding soup to drink, and when the prince tried to run away he struck him with a knife and wounded him so severely that he fell to the ground covered with blood. Arnolfo was sent for. "Cure my good servant there," said the Czar, "I have been playing with him rather carelessly." "So carelessly," answered the doctor, "that perhaps God and your Majesty will raise the dead, for the breath has already gone out of his body." The Czar waved his hand, called the dead man a "dog," and went on with his amusements.

An incident such as that just narrated throws a lurid light on the character of the times and of the ruler who subsequently earned the title of "The Terrible," though, like all isolated incidents, it shows but one side of that curiously complex personality, in whom good and evil had a prolonged struggle for the mastery, but in whom the final triumph of evil was so complete that what good there was in him has been almost altogether lost sight of in the memory of his crimes.

Ivan the Terrible has not infrequently been compared with King Henry VIII. There seems, however, little to justify the comparison, save that each had a particularly strong will and each married six wives. The Russian, unlike the English ruler, was on the point of marrying a seventh, or, to speak more strictly, was negotiating a seventh marriage, when he died. Had he lived it is doubtful if the marriage would have taken place, for the English lady whom he asked to share his throne was not over eager to leave her own country, and seemed to think that the perils and drawbacks of becoming wife to a man like the Czar were fully as great as the attractions of an Emperor's crown. The negotiations for this match are closely associated with the names of two medical men of widely opposite characters and careers, the physician-ambassador, Robert Jacob, and the miscreant Bomel. It is sometimes stated that Ivan IV. made a proposal of marriage to Queen Elizabeth herself. But this was not the case. The idea was suggested to him, but it was not probable that he seriously entertained it as a practical possibility. The suggestion is said to have been made to the Czar by this same Bomel, a good-for-nothing Anglo-German, the story of whose eventful career is not unprofitable reading. This man, Elisœus Bomelius in full, was the son of a Lutheran preacher and was born at Wesel in Westphalia. He was sent to England and educated at Cambridge, where he graduated as Doctor of Medicine. At this time his evil propensities had not shown themselves, and he was well received by the English reformers, to whom he had letters. Melanchthon is said to have praised him highly for "erudicion and godlynes." After graduation he went to London and soon gained a high repute as physician and astrologer. "People resorted to him to be cured of their sicknesses, having a wonderful confidence in him and in his magic." He even gained the ear of Sir William Cecil, who is said to have consulted him as to the probable length of the Queen's life during one of the negotiations for her marriage. In 1567 Bomel was arrested at the instance of Dr. Thomas Francis, the President of the College of Physicians, for

[5] Reigned 1533 to 1584.

Digitized by Google

practising medicine without licence from the College, and was thrown into the King's Bench Prison. There he lay for a couple of years, writing to Cecil vindictive letters, in which he spoke of Francis's ignorance of astronomy and Latin, while petitioning Cecil and later Archbishop Parker for his release. The Archbishop wanted to send him abroad, but Bomel gained time by concocting a tale that he had an important secret to divulge—that he had knowledge of a great danger hanging over England. The Archbishop, suspecting a conspiracy, passed him on to Cecil. The important secret proved to be nothing more than the vague statement that, as great revolutions occur every 500 years, and as that time had passed since the Conquest, something terrible might be expected to happen shortly. Cecil treated the author of this rubbish with the contempt he merited, though, as has been remarked, if his "prophecy" had come only a few years later, at the time of the Armada, his fate might have been a different one. As it was, he accepted a most opportune offer to join the suite of the Russian ambassador Savin, who was then in England and on the point of returning to Moscow. Late in 1570 he was settled in the Russian capital. The English ambassador, Jerome Horsey, who began his travels in 1572, frequently met Bomel; he found him living in great pomp and luxury at the Court of Ivan, with whom he was in great favour as a magician. According to the Russian historian Karamzin he was for a time the Czar's evil genius, poisoning his mind against the *boyars* or nobles, foretelling rebellions, and prompting him to some of his worst persecutions. But Nemesis overtook him at last. The wicked doctor, together with the Bishop of Novgovod, was discovered in treasonous correspondence with the kings of Sweden and Poland, with whom Russia was then at war. His dreadful fate cannot be better told than in the pregnant words of Horsey, who was in Moscow at the time. "The bishop, upon examination," he writes, "confessed all. Bomelius denied all, hopinge to fare the better by means of some of his confederates, as it was thought, favouretts neare about the Kinge, whome the Emperor was appointed to attend his son Charowich [Czesarévitch] Ivan; to examine the said Bomelius upon the racke; his arms drawen backe disjointed, and his leggs stretched from his middell loynes; his backe and bodie cutt with wyer whippes; confessed much and many things more than was written or willinge the Emperor should knowe. The Emperor sent word they should rost him. Taken from the *pudkie* [or rack] and bound to a wooden pool or spitt; his bloudye cut backe and body rosted and scorched till they thought noe liff in him; cast into a slead, brought thorow the castell; I preste among many others to see him; caste up his eyes naminge Christ; cast into a dungeon and died there. He lived in great favour and pompe; a skilful matimitician, a wicked man, and practicer of much mischieff. Most of the nobles were glad of his despatch, for he knew much by them. He had conveyed great ritches and treasure out of the country by way of England to Woesell in Weostvalia, where he was bowrn, though brought up in Cambridge. An enymie alwaies to our nation. He had deluded the Emperower, making him belive the Quen of England was yonge and that yt was very feacable for him to marrie her, whereof he was now out of hoep." One turns with a shudder from this hideous picture of suffering. The wretched man's widow, an English-woman, remained in Moscow until 1583, when the English ambassador obtained leave for her to quit the country and return to England. His reference to the matter is very brief. "Obtained leave," he writes, "Jane Ricards, the widow of Doctor Bomelius, who for treason with the King of Pole against the Emperor was roasted to death at the city of Moscow in the year 1579."

A very different man was Dr. Robert Jacob. The Czar wrote to Queen Elizabeth in 1580 asking her to send him an experienced physician, and the Queen recommended Dr. Jacob, or Jacobi, one of her own body-physicians; not, as she stated in her reply to the Czar's letter, that she herself had no need of him, but because her "brother in the blood," as she called the Czar, required him. Jacob seems to have been a man of considerable attainments. He was a native of London and a graduate of Basle and of Cambridge.[6] It was in 1581 that he sailed in a fleet of merchantmen which Jerome Horsey was conducting from England to Russia. On arriving in Moscow he was for some time maintained by the Russia Company, until the Czar gave him a regular stipend. Jacob was not long in Russia before his influence was felt at the Court of Ivan. Some slight trace of conscience, it may be supposed, was still left to that extraordinary person. After committing on his people a series of atrocities of a nature which a few years ago would have been known as "Bulgarian," but which in future will perhaps be more familiar as "Armenian," he appears to have felt, if not remorse, at least a fear that the people would rise and avenge their wrongs upon the author of them. This, quite as much as the expectation that political advantages to Russia would follow, made him anxious to find an ally in England. His relations with Elizabeth were already of the most friendly character, and he had already secured her promise of welcome and protection if he should be forced to fly for safety from his own subjects. But he now proposed to form a new bond of union between the two countries by marrying an English-woman. The fact that he had two wives living at the time was no obstacle to the autocrat. One had already been put away, and the second could be forced into a nunnery. So he turned to Dr. Jacob, who, in addition to being a physician, acted much as an ambassador from the English Court, and asked him to recommend a *nevièsta*, maid or widow, worthy to share the Imperial throne. The doctor mentioned the name of Lady Mary Hastings, the daughter of Lord Huntingdon, and related on her mother's side to Queen Elizabeth. He so dwelt upon the charms of this lady that he quite captivated the imagination of the Czar, who, doubtless, was also not unmoved by the fact that the proposed bride was nearly related to the Queen. The result was that Ivan at once despatched a special ambassador to London with instructions to arrange conditions for a close Imperial union between England and Russia, and to see the Queen privately and tell her as a secret of the Czar's wishes as to marriage. He was also to see Lady Mary Hastings and report to the Czar whether she deserved the eulogiums that Jacob had passed upon her. The man chosen for this important mission was Theodore Pisemski.

It is beyond our province here to tell the story of Pisemski's mission, of his interviews with Elizabeth and the delays under various pretexts before he could see the bride-elect. She, poor creature, was only just recovering from the small-pox, which had destroyed her beauty for ever. Pisemski reported to the Czar as he had been commanded to, but his report was a mere inventory of the lady's features—about as graphic as the description of the person on a modern Russian passport. It contained not one word in praise of her beauty or personal charms. The Queen was also very doubtful of the effect which the sight of Lady Mary's scarred and disfigured face might have upon the Czar. The person most concerned, the Lady Mary herself, at first favoured the idea of the marriage, but her view altered when she came to know more of the man she was asked to marry and of the country she was invited to share in ruling. Pisemski consequently returned to Russia in 1583, having failed in this

[6] He was a Fellow of Trinity, took his A.B. in 1569, and A.M. in 1573. He then went to Basle, where he graduated M.D., and was incorporated on that degree at Cambridge in 1579. In 1585 he became Licentiate of the College of Physicians, and Fellow in 1586.

part of his mission. He was accompanied by an ambassador from Elizabeth, the famous Jerome Bowes, who was instructed to settle all matters commercial, political, and secret then pending between the two countries. Bowes is described as a man rough in his manner and obstinate—one who in his first word showed himself determined not to yield a point. This mission was beset with difficulties, but it was brought to an abrupt end by the illness and death of the Russian autocrat. Ivan the Terrible, living up to his name to the last moment, died on March 18th, 1584. His faults are known to all. Let one small fact, infinitely minute in the balance though it be, be placed to his credit here. While his own subjects were groaning under the most monstrous tyrannies the world has ever seen, while the foreign merchants, and even the foreign ambassadors at his Court, were frequently subjected to the grossest indignities and even dangers, his English physicians were for the most part treated with respect and justice. If the fact be but a small palliation of the tyrant's crimes, it is a proportionally great tribute to the moral worth of those who met with such exceptional treatment.

Of the physicians at the Russian Court during the reign of Ivan the Terrible Robert Jacob was by far the greatest. Of the others scarcely more than their names remain. Ralph Standish, Richard Elmes, Reynolds, Richert (or Richard), the apothecaries Thomas Carver[7] and James Frencham—these are a few of the Englishmen whose names the records of the time have preserved. Only one (the last named) has left any more permanent mark in history. Frencham is said to have founded the first *Apteka* in Russia—a peculiar and important institution to be described more fully later. Jacob returned to England very shortly after the death of Ivan, but was again sent by Elizabeth to the new Czar Feodor, who required a skilled obstetrician to attend the Empress Irene in her confinement. Neither Jacob nor the midwife who was sent with him, however, reached Moscow, the practitioner returning to England and the midwife being detained for some obscure reason at Vologda for over a year. But the Czar soon wrote again to the Queen begging her to send him another physician. Elizabeth wrote in reply to Boris Godunof, the Master of the Horse to the Czar, who later himself sat on the Russian throne:—"And whereas wee were advertised by our marchands that your lordship was desiry to have an English physician to be sent over for the service of the Emperour, and having byn also moved and solicitted by our Cheife Councellor and Lord High Treasurer of England, William Lord Burghley, to send over one of our owne Doctors of Physick, commended by us to His Matie, wee, applying ourselves and being willing and ready to assent, either to this or to any other thing that may lyke His Matie, have appointed Mark Rydley, one of our Physicians, to undertake this voyage and service, *a man learned and expert in his profession* and fitt for the service of a Prince, who being required hereunto by us, upon notice had of your Lo. desire and estraverged from his

country, wee do *commend* to your honourable favour to be protected and graced by your Lo. *according to the quality of the man*, whom we doubt not but your Lo. shall find to deserve your good lyking and favour." Mark Ridley,[8] the doctor mentioned in this letter, was the son of an English clergyman. He was a Cambridge graduate and Fellow of the College of Physicians, and a learned authority on magnetism, a subject upon which he published several works. He stayed at the Court of Moscow for about four years, until the death of the Czar Feodor in 1598, when he returned to England. He seems to have held a high position in his profession, being Censor of the College of Physicians on eight occasions and treasurer twice. He died in 1624.

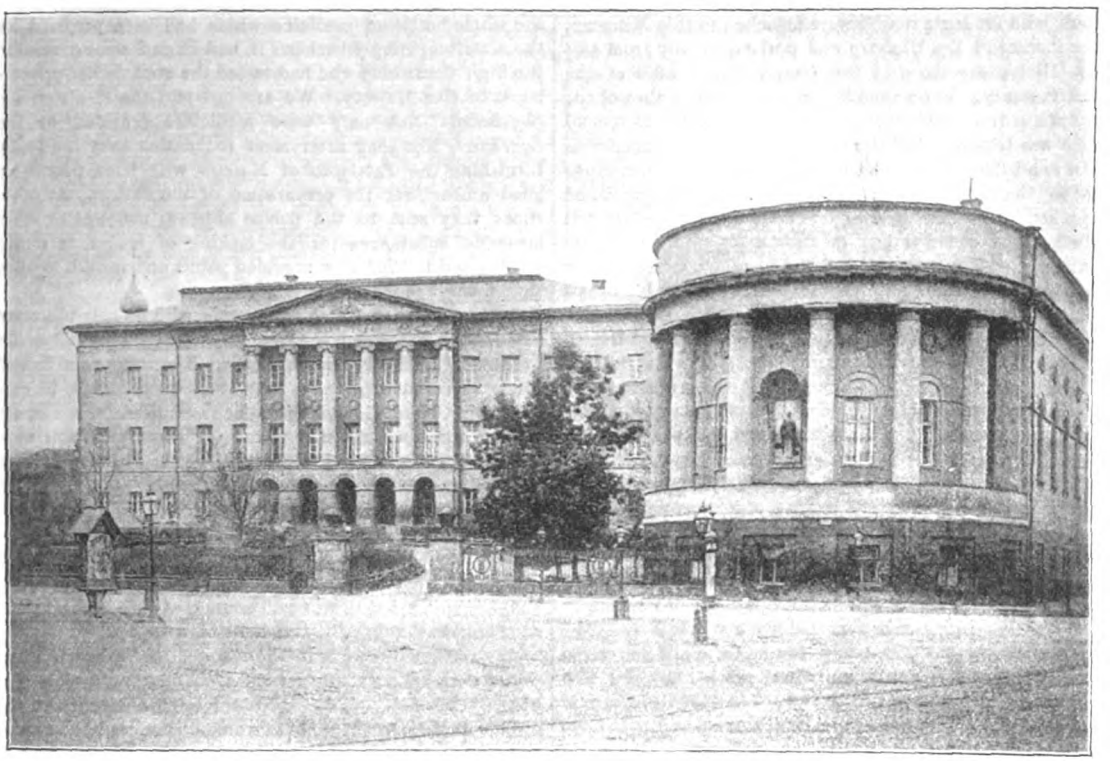
After the death of the Czar Feodor the Russian throne was occupied by Boris Godunof, who is generally called a usurper. It is true he had no royal blood in his veins, but Elizabeth recognised him, and three months after his accession wrote him a letter of congratulation on his selection by the Russian people, in which she gave him all the full and numerous titles of a Russian Czar. It was in this letter that she asked him to "grant lycence" to Mark Rydley, "our subject, Physician to the late Emperour, to returne him hither to his natyve country, for that they have shewed us that dyvers causes nearly concerning his private state doe require his being here and cannot be ordered without hym." A year later Boris Godunof, who probably missed the services of Rydley, wrote, just as his predecessors had done before him, to Queen Elizabeth, requesting her to send him an English physician On this occasion the negotiations were not quite so successful as before, though not from want of goodwill on the part of the English Queen, nor from any professional disqualifications on the part of the doctor she selected. This was Dr. Thomas Willis, who must not be confounded with his more distinguished namesake, the famous Oxford professor and physician to Charles II. The Dr. Willis of Elizabeth's time went to Russia with the Queen's warmest recommendations, but unfortunately she at the same time gave him some instructions of a political character. This was quite enough to rouse the suspicions of Boris, who did not feel himself very firmly seated on the throne and was ready to scent danger in the most trifling circumstances. He determined, therefore, not to receive the English doctor, but in order to avoid offending the Queen he had recourse to a little diplomatic subterfuge. He arranged that the foreign doctor should undergo an examination as to his knowledge and fitness to practise before being allowed to settle in Moscow. This earliest of medical examinations held in Russia was entrusted to Shtchelkalof, the Russian Chancellor, an official with notorious anti-English prejudices, who carried through the farce admirably. "You call yourself a doctor," he said to Willis; "but have you any doctor's diplomas, or doctor's books, or healing herbs with you?" "All my doctor's books and herbs I left behind me at Lübeck," answered the doctor, "in order to hurry on here." "And how do your recognise sicknesses in man; by the water or by the pulse?" "One does not need books to tell diseases," answered Willis. "A slight malady one tells by the water and a severe one by the pulse. Besides," he added, "I *have* a grand book of medicine with me; it is here, in my head," and he rapped his forehead as he spoke. The examiner was, of course, not satisfied with these answers, and the rejected doctor was sent back to his native country. He was apparently the only English medical man who went to Moscow during the usurper Boris's reign. After the death of Boris in 1605 political affairs in Russia became of a highly complicated character, although it is unnecessary here to follow the fortunes of the false Dmitris and the Shuiskis, pretenders who held the throne of Moscow for periods to be reckoned by weeks or days, or the fluctuations of the never-ending wars between Russia and Poland, during which affairs in Russia were almost as chaotic as during the period of Tatar invasions three centuries earlier. These troublous times—*Smutnuia Vrémeni*, as they are well named in Russia—came to an end in 1613, when something like order was restored by the election to the throne of Michael, son of Philaret, the Metropolitan of Moscow.

[8] Mark Ridley, or Rydley, was the son of Lancelot Ridley, the rector of Stretham, near Ely, where he was baptised in 1559. He was at Clare College, Cambridge; graduated A.B. in 1580, A.M. in 1584, and was admitted L.C.P. in 1590; took his M.D. Cantab. in 1592 and F.C.P. in 1594.

IV.

The Accession of the Romanoffs.—The Aptekas and the Aptekarski Prikaz or Ministry of Medical Affairs.—Foreign Medical Men in Moscow of the Sixteenth Century.

THE accession of Michael, the first of the Romanoffs, is an important epoch in Russian history, and as many readers of these notes may be unacquainted with the general outline of that history it may help them to "fix" this epoch by adding that Michael was the grandfather of Peter the Great, and that he reigned from 1613 to 1645. But the main importance of his reign in the present connexion is that during it was organised a very remarkable institution—a Ministry of Medical Affairs—of interest not only in itself, but also as being the germ whence sprang the present highly organised medical bureaucracy which now exists in Russia.



Each of the various departments of Government in Russia in the seventeenth century was known as a *Prikaz*, a word which, in the sense in which it was then employed, is now obsolete, but which may be translated as a Ministry. Among the various Ministries, not the least important appears to have been the *Aptekarski Prikaz*, or Ministry of Affairs relating to Medicine. The exact date of its institution is not known. Some ascribe it to the end of the sixteenth century. It was certainly in existence early in the seventeenth century. It seems to have been a development of another institution, the *Apteka*. This was at first merely the central store for the distribution of drugs to persons about the Court of Moscow. It was founded about the year 1581 by one of the numerous English apothecaries who entered the Czar's service. Of this Englishman, unfortunately, not very much is known. His name was James Frencham,[9] and he seems to have gone to Russia at the same time as Dr. Jacob, whose career has already been sketched. He was certainly in Moscow in 1581, when he instituted the Court *Apteka;* then he seems to have returned to England, but twenty years later he is the subject of quite a series of letters between Queen Elizabeth and the Czar Boris Godunof, showing that he again desired to join the Czar's service. Accordingly, in 1602, after an unusually long delay on the road, he again arrived in Moscow, this time with his wife and family, and a whole supply of drugs, of which, fortunately for the curious in such matters, a list is preserved. Whether Frencham had anything to do with founding the *Aptekarski Prikaz* is not clear. All that is known is that it grew in some way out of the *Apteka*, which he is known to have founded. The *Prikaz* was organised in exactly the same way as the other Ministries. One of the highest *boyars* or nobles was always at the head of it. Thus in 1637 it was under a Tcherkasski, in 1642 under a Sheremetief, and in 1662-88 under a Miloslavski. Let us glance for a moment at what constituted this seventeenth century Ministry of Medical Affairs.

Apart from the clinical staff the members belonged to the following six groups: 1. Doctors—i.e., physicians. 2. *Lékars*—i.e., surgeons. 3. *Aptekars*—i.e., apothecaries in connexion with the Court *Apteka;* under them were

alchemists, distillers, pupils, and *travniki*, or persons who collected *travni*, or healing herbs. 4. Oculists. 5. Barbers, blood-letters, bone-setters, and undertakers. 6. Clock-makers, who for some reason were attached to this Ministry.

The income of the Ministry was derived mainly from two other Ministries—those of the Grand Palace and of the Grand Treasury. For a time its history is merely that of the old *Apteka* from which it had sprung. Later a second *Apteka* was founded, and the two were known henceforth as the Old and the New. The Old continued to serve out drugs only to the Czar, the Court, and to more distinguished foreigners. The New *Apteka*, however, was allowed to sell medicines and other things to the troops and to private individuals, and it was even ordered to take concern for the health of the citizens and for the prevention of infectious diseases. So that as early as the middle of the seventeenth century there was the nucleus in Russia of a Public Health Service. In the following pages the stages in history which connect those early beginnings with the present system which prevails in that country will be briefly indicated. But before doing so a little more has to be said about the Old and New *Aptekas*.

It is tempting to dwell on those still early days, when the first rays of western civilisation were beginning to dawn on the Muscovite Empire, but before Peter had forcibly flung open his famous "window that looked to the west," and which let in, with much-needed light and air, some other elements less desirable. It is a fact perhaps not generally recognised that before the great Reformer's time Russia had not only begun to look to the west and to adapt herself to western ideas of civilisation and development, but had also begun to advance on lines of her own. Thus the *Aptekas* just described, although founded by an Englishman, appear to have been thoroughly Muscovite institutions and were not modelled on any similar institution in another country. Thanks to the reprint by the present Russian Medical Department[10] of the books and documents of the *Aptekarski Prikaz*, we can form to ourselves a complete picture of these institutions and their working. We learn not only the accepted medical traditions of the time and country, the names given to their ailments and the drugs used to cure them; but we can gather some idea of the social condition of the people and the social ideas then prevailing. We see one *Apteka* for the *boyars* and one for the common people; we can read the abject petitions (the abjectness doubtless more than formal) of private persons desiring treatment or medicine. One Theodore Baranof has his right hand nearly blown to pieces by an arquebuse and humbly begs the privilege of a surgeon's aid, which the Czar Michael graciously permits. Here is the ceremonial observed when the Czar himself had to take a dose of medicine. A special set of drugs was kept for His Majesty in a separate room, locked and sealed by the secretary of the *Prikaz*. Without his consent no one, not even the imperial medical men and apothecaries, could enter the room. The drugs were kept in sealed bottles and boxes. The prescription written by the medical man was first submitted to the *Prikaz*, who entered it in their books, and was then presented as a *skazka*, or official paper, to the Czar, who gave the order for its preparation. It then passed to the *Apteka*. Here only the most trusted medical men and apothecaries took part in the preparation, working in a separate room to which no one else had access. And now, when all was ready, the medicine was tasted by a whole series of official persons: firstly, by the doctor who had prescribed it; secondly, by the president of the *Aptekarski Prikaz;* and lastly, by the high Court official who carried it up to the Czar. Dr. Rosenburg, body physician to the Czar Alexis (Peter the Great's father), relates that he once had to swallow the whole bottle of medicine which had been prepared for the Czaritza, simply because it had caused some nausea to the high Court lady who had tasted the stuff before presenting it to Her Majesty. We are not told the result on the physician. Not only were medicines provided by the *Aptekas*. Not long after their foundation they are found furnishing the Patriarch of Moscow with "ten pounds of good amber" for the preparation of the chrism. At other times they sent to the palace aniseed, molasses or other aromatic substances for the making of *vodkas* or strong drinks, and in 1707 they provided paints and varnish to paint the imperial yacht at Voronezh.

Of the medical practice of the time, with its poly-pharmacy and its use of curious and sometimes very rare and costly drugs, not much need be said here. The recipes and lists of drugs correspond closely with the same things in contemporary medical books in other countries. Occasionally strange remedies are met with. By great good fortune a complete inventory is preserved of the contents of a travelling medicine chest which was prepared for the Czar Alexis on the occasion of one of his journeys to the Great Monastery of the Trinity, some forty miles from Moscow. In the list of oils, elixirs, essences, syrups, salts, plasters, and powders, there occur a "syrup of colts' hoofs,"[11] a "spirit of worms," another of ants, and a balsam of "unicorns' horns." The horn of a unicorn was a most highly esteemed remedy in those days. Sometimes fabulous prices were not only asked but given for even a piece of a horn. For instance, in 1655 a foreigner brought to the *Prikaz* in Moscow three horns which he declared to be those of unicorns and offered them for sale at the enormous price of 10,000 roubles.[12] Dr. Graman, a physician who had studied at Jena, Leipzig, and Wittenberg, gravely reported upon these horns to the *Prikaz*. He declared that they were undoubtedly what they professed to be, and that two of them were extraordinarily fine specimens, and he therefore proposed that for these two alone a sum of 5000 roubles should be offered. The *Prikaz* ultimately decided to offer 5300 roubles for all three horns, but if the vendor refused to take less than the original sum, to pay that rather than lose the horns. The ultimate result of this bargain is not stated. It may be noted in passing that the price of the horns was to be paid at the wish of the vendor in sable skins and other peltry. This was a frequent medium of exchange in Russia at that time. The therapeutic uses of unicorn's horn, or whatever it was that passed for it—it was in all probability the horn of the rhinoceros—were numerous and varied. It was mainly apparently a prophylactic, invaluable against fevers, pestilences, and even the bites of serpents. According to Dr. Belau (physician to both the Czars Michael and Alexis) it was "a certain protection against plague, small-pox, and dysentery." He had sufficient belief in it to take it himself, at least on one occasion, when he swallowed a dose of twelve grains in two tablespoonfuls of hot Rheinwein, taking measures to encourage diaphoresis after the dose. He was the fortunate possessor of a small piece of horn weighing a quarter of an ounce, and in exchange for this he asked not less than twenty sable skins.

No little store was also laid by certain magic stones. The same Dr. Belau offered the *Prikaz* a whole collection of such stones. One of these if worn near the kidneys cured renal complaints; others had only to be soaked in water and the water acquired marvellous healing powers in disease of the

[10] Richter, whose work on Medicine in Russia has usually been the leading authority for this branch of history, was deprived of the use of these documents, as he believed they had been destroyed in the burning of Moscow in 1812. They were, however, safely preserved among the archives of the Ministry of the Interior.

[11] Possibly, of course, a plant of that name.

[12] Equivalent to at least 60,000 roubles, or over £6000, at the present day.

eyes; yet another had a wonderful influence over pregnant women, for if worn round the neck of the woman it gave strength to both mother and child. In fact, there was scarcely a disease or a part of the body which had not its own particular magic stone. Few of the drugs used at that time were of native production. They came from Germany, Holland, or England. English merchants trading to Archangel found a ready market for such goods, and in addition the foreign medical men who came to Moscow always brought a goodly supply of drugs with them. The list of drugs already mentioned, which Frencham, the English apothecary, took with him, contained the names of no less than 164 different substances or preparations. Later efforts were made to develop the native resources. *Travniki* — that is to say, collectors of *travni*, or simples used by the peasants, were appointed by the *Prikaz*. The enormous tracts of Siberia were laid under contribution. The Siberian *voyevods*, or military governors, were ordered to make local inquiries as to the herbs of popular repute in their district, and to send samples of such as were used to Moscow. The record remains of the appointment in 1669, by the governor of Yakutsk, of an official named Epishef who travelled for two years on a botanical excursion, and published on his return a brief description, still extant, of the herbs he had collected and their uses—a sort of miniature Siberian Pharmacopœia of the seventeenth century. Later in that century attempts were made by the *Prikaz* to cultivate medicinal plants in botanical gardens in and around Moscow itself. The word "*travniki*" was also applied to certain popular manuscript books which described the nature and properties of the herbs and simples in common use. The descriptions in these books are a curious mixture of common sense and superstition. The one most commonly appealed to was known as the *Leitchebnaia Kniga*, or Book of Treatment, a translation from the Polish, which treated of simples, of distillation, of tinctures, of precious stones, of philosophical knowledge, of blood-letting, of the apothecary's and barber's arts—in fact, a sort of epitome of the medical knowledge of the time, addressed as much to the careful housewife as to the professional apothecary. An original copy of this book perished, with innumerable other valuable manuscripts, in the great fire of 1812.

Meanwhile, the stream of foreign medical practitioners continued to flow to the Russian Court. During the reign of Michael eight physicians, five *lékars* or surgeons, and four apothecaries entered his service. In the reign of his son and successor, Alexis, the numbers were larger, though the reign was shorter by a year; eleven doctors, three *lékars*, six apothecaries, and one eye-doctor entered his service. In Feodor's brief rule of five and a half years (1676 to 1682) four doctors, nine *lékars*, and six apothecaries came from abroad to Moscow. Feodor was succeeded by his half-brother, Peter the Great, whose reign must be reserved for more detailed treatment, but it may be noted here that in the first seventeen years only of his reign as many as eleven doctors, eighty-seven *lékars*, one eye-doctor, and nine apothecaries arrived in Russia. It is impossible here, and would serve but little purpose, to name even a fraction of these numerous foreign practitioners. But a few names undoubtedly deserve mention. Indeed, it is a remarkable fact, upon which it is well to insist, that the majority of the foreign medical men who went to Moscow in the sixteenth and seventeenth centuries were men of considerable standing. They were by no means the scum of the profession in other European States or adventurers who, having failed in their own country, were playing pitch-and-toss with Fortune in a new one. On the contrary, they were nearly all men with good university degrees, and provided with recommendations from their own sovereign to the Russian ruler. Without some such recommendation they would not have been accepted at Moscow. It was impossible for a private individual to make his way to the Russian capital and then start practice. To begin with, such was the state of the roads that without an *opasnaia gramota*, or letter signed by the Czar guaranteeing a safe journey, he could never have reached Moscow alive. If by a miracle he had reached the capital he would at once have been arrested, and then the best he could have hoped for would be a safe escort to the frontier. On the other hand, those who came with proper credentials were treated with every consideration. Let us, for example, try to follow the fortunes of an English medical man invited to Moscow about the middle of the sixteenth century. A detailed correspondence on the matter may be supposed to have passed between the Queen and the Czar. This correspondence was sometimes prolonged over several months, or even a year or two. When all was settled to the satisfaction of both parties, the practitioner chosen would probably sail to Archangel in a fleet of English merchantmen belonging to the newly formed Russia Company. Or he might join the suite of an English or Russian ambassador going or returning to Moscow. Having safely accomplished the sea voyage and landed at Archangel, the long overland journey to Moscow would begin—a distance of over 600 miles to be traversed either on horseback or in carriages. To accomplish this safely a passport, the so-called *opasnaia gramota*, was, as already stated, essential. This document sometimes guaranteed not only a safe conduct to Moscow but also, in case the bearer should wish at any future time to go back to his own country, a safe return to the frontier. Journey money was provided and also a fixed daily supply of provisions. Rather more than halfway to Moscow, at Vologda, the party of travellers would be met by a special escort from the Czar to bring them on to the capital. Arrived in Moscow he was assigned a set of rooms or a house, most probably inside the Kremlin. Here the very first act demanded of him was to subscribe an oath of fidelity to the Czar, in which the medical man bound himself most solemnly not to use poisonous drugs, or to do anything by thought, word, or act to the hurt of the Czar or to any member of the Royal family. The fear of being poisoned or bewitched seems to have been constantly present in the minds of more than one Czar, and the precautions taken against such a disaster have already been seen in the description of the ceremony observed when the Emperor required a dose of medicine. It is even said that the Emperors Feodor and Boris Godunof declined under any circumstances to take medicine from their foreign medical men, though they more than once called in *kudesniks*, or wizards (even then not an extinct race), and took their simples readily enough.[13]

After taking the oath, the doctor whose fortunes we are following was taken to the *Posolski*[14] *Prikaz*, or Foreign Office, thence to the *Aptekarski Prikaz*, and finally had an audience of the Czar. Then followed a curious and pleasant custom, though one strongly tinged with orientalism. The Czar sent the new-comer a quantity of handsome presents, technically known as the "presents on arrival." Here is the list of articles sent to Dr. Sibelist, a famous physician in his day, when he arrived in Moscow early in the seventeenth century:—Undefined quantities of velvet, "black and smooth"; velvet of a coarser quality, and satin; two pieces of damask and two of cloth; forty sable skins worth 40 roubles, and 40 roubles in

[13] A tale is told of a *médecin malgré lui* in the time of Boris Godunof, which, if not true, is certainly drolly apposite. The Czar being taken ill a proclamation was made offering high rewards to any person who would cure him. A certain *boyar's* wife, who had some grudge against her husband, scented a fine opportunity for revenge. She went to the Court and stated that her husband knew of a remedy which was a certain cure for the Czar's disease. The *boyar* was sent for and at once questioned as to his remedy. Denials and professions of ignorance were of no avail. He was beaten and threatened with torture and even with death if he did not at once treat the Czar. So the wretched man begged a respite of fourteen days, hoping some *deus ex machinâ* might be forthcoming in that time. During the interval he collected some herbs and some earth from the banks of the River Oka, and as a last resource proposed that the Czar should bathe in an infusion of these. To his surprise and joy the Czar actually recovered after his bath. But the poor *boyar* was not out of his fix yet. It was clear that he had known of a remedy all along, and as he had refused at first to name it he must have wished the Czar to die. So he was beaten within an inch of his life, and then, with a fine inconsistency, as he had ultimately cured the Czar he was dismissed with a reward of 200 roubles and an estate of eighteen serfs, granted him on condition that he did not take vengeance on his wife. The couple are declared to have lived "happily ever after."

money. To his wife were sent at the same time quantities of damask, taffetas and cloth, and forty sables worth 25 roubles; and to his servants pieces of "English cloth, each of the higher servants receiving in addition 8 roubles in money. Even the kitchen-maid and cook were not forgotten, each getting her modicum of cloth. These for the outer person. But the inner man was not forgotten, and numbers of good things were despatched from the Czar's table to that of his new Court physician. The same Dr. Sibelist received three loaves of bread, a quarter of beef, a goose, two ducks, a hare, two woodcocks, a sheep "with the wool on," five chickens, six half-pounds of butter, eight eggs, a flagon of *boyar* wine, two flagons of *romanei* (a kind of sweet wine) and two of Rheinwein; two each of cherry mead, raspberry mead, molasses mead, and another sort of mead; one *vedro* (two and a half gallons) of still another kind, and four *vedros* of "prince's mead"; one *vedro* of "artificial" beer, and two of "simple" beer.

The stipend paid to the foreign physician, if not on so prodigal a scale as the presents made to him on his arrival, was not an ungenerous one. In the time of Boris Godunof a doctor received 200 roubles a year and twelve or fourteen roubles a month. It is not easy to give an exact equivalent of these sums in the money of to-day, but it seems probable that taken together they amounted to a very considerable sum. But in addition to this he was provided with a house, with a monthly supply of bread sufficient for his whole household, and with sixteen "loads" of firewood, four barrels of mead, and four of beer every month. He and his servants were vast consumers of strong drinks. In addition to those just named there came daily to his house from the Czar's kitchen one and a half quarts of *vodka*, the Russian rye spirit, as well as the same quantity of vinegar and a side of bacon. Every day the Royal table furnished him with three or four dishes, each "so heavy that the strongest man could with difficulty lift it." Other material wants were also liberally provided for. Four good horses were sent from the Royal stables for his use, and sufficient hay and straw for seven horses were furnished every month. One still better horse was given him as a saddle-horse, to be used specially when he made his morning visit to the Kremlin and the *Court Apteka*, a visit never omitted in the summer months. Then there was a special horse for sledging in the winter, two horses for his wife "with which to drive to her own church," and a carthorse "to get in the water." To some, if not all, of his foreign physicians the Czar granted a small estate of some thirty or forty "souls"—i.e., serfs. Special presents on special occasions also—such as the successful treatment of a great *boyar*, or *à fortiori* of the Czar himself—were not infrequent. In the latter case he might get a piece of valuable damask or velvet, or forty fine sables as a present. Altogether, the lot of the foreign practitioner who was invited to the Muscovite Court in the sixteenth century was by no means an unenviable one. It had its drawbacks, doubtless, but so long as he kept the Czar's favour he had nothing to fear and was treated as the equal of any *boyar* or noble in the land. It was only by the people that the foreign practitioners were mistrusted, apparently because they regarded them and their strange doings as embodiments of the powers of evil. It would have gone hard with many of them had they not been under the protection of the Czar. On more than one occasion of popular outbursts in the city of Moscow their houses are said to have been the first to be sacked by the mob.

Among the more noteworthy physicians who went to Moscow in the seventeenth century a few have to be named. They were English, Dutch, German, and Italian. In 1621 Dr. Arthur Dee, body physician to King James and later to King Charles, went to Moscow with the King's recommendation, and stayed there for fourteen years. He wrote a treatise while there on the "Hermetic Science," which was published in Moscow, and later in Basle and Paris.[15] After Dee came Sibelist from the University of Halle, recommended by the Duke of Holstein; then, in 1639, Graman, who had studied medicine in Jena, Leipzig, and Wittenberg, and was recommended by the famous Holstein ambassador, Olearius. Four years later came Belau, with the diplomas of Leyden and Königsberg. Samuel Collins, an Englishman, is said to have made a greater name than all his predecessors at the Russian Court. He was the son of an Essex clergyman and a graduate of Padua and Oxford. He was nine years in Moscow, and the year after his death, which took place in Paris in 1670, there appeared a small anonymous book entitled "The present state of Russia in a letter to a friend in London, written by an eminent person residing at the great Czar's Court at Moscow for the space of nine years." There is no doubt that this work was from the pen of Collins. Apparently it was never intended for publication, but was merely a series of private letters addressed to "an eminent Doctor of Physick here in London." The book is quaint and interesting, even if it throws no particular light upon the state of medicine at that period, or the treatment received by the foreign practitioners at the Russian Court.

The name of John Tradescant must not be passed over without brief reference. The true founder of the great Ashmolean Museum in Oxford, which might more appropriately have been called the Tradescant Museum, and the earliest collector of all that is interesting in natural history, he has fallen into quite unmerited oblivion. John Tradescant, generally known as "the elder," to distinguish him from his son, was a Fleming by birth who had settled in London and held the honourable position of gardener to the Marquis of Salisbury and to the King (Charles I.). He had travelled much in Europe, and one of his journeys led him to Archangel in company with Sir Dudley Digges. Digges's expedition was apparently a commercial one, but he only reached Cholmogory, where he had to turn back on account of the Poles. Tradescant seems to have got no further than Archangel; but he made a great collection of natural history specimens and other curiosities gathered in the neighbourhood, and these he brought to London and deposited in his growing museum in his house at Lambeth. "Tradescant's Ark," as the house was called, soon became one of the sights of the town, and was visited by the King and Queen and the highest in the land. The old naturalist died in 1638. The collection, which included specimens of minerals, birds, fishes, insects, plants, coins, medals and all sorts of curiosities, passed to the son and on his death to the grandson, who died in 1659. Having no heirs, this last representative of the family left the museum to Elias Ashmole. Ten years later the University of Oxford offered the degree of M.D. to Ashmole, and about the same time the latter offered the whole Tradescant collection to the University, provided that they would erect a suitable building for it. The Ashmolean Museum, as it was henceforth rather unfairly called, was designed by Wren, and opened in 1683. The name of Elias Ashmole has another claim to mention here, as he published an English translation of the treatise on Hermetic Science by Dr. Arthur Dee, to which reference has just been made above.

Of the medical men of German and other nationalities space will permit no more than the mention of two or three. Rozenberg came to Moscow with the diploma of Königsberg University; Blumentrost was a graduate of Jena; Carbonarius of Grätz; Pelarino of Padua. But with these names, all of which appear at the end of the seventeenth century, begins a new era of medicine in Russia. Peter the Great had already not only come to the throne, but had begun to show the stuff he was made of. The old order was giving way to the new. Among the wonderful reforms, or rather new creations, of his great genius not the least wonderful must rank his successful endeavours to nationalise medicine as he had nationalised the other arts and sciences.

V.

The Early Russian Hospitals and Russian Medical Education.—The Medical Chancellery.

BEFORE the reign of Peter the Great there does not occur the name of a single Russian in the medical hierarchy of the Muscovite Court. There were no means by which a native Russian could obtain a medical education in his own country, and the idea of going abroad to study at a foreign university, even if he had entertained it, was one which possessed no attractions to a Russian of the pre-Reform period. The great reformer himself was the first Czar who left his country for reasons other than warlike; and it is extremely doubtful whether his example alone would have induced others to follow it. Peter was not the man to wait until his example was voluntarily followed. He saw the

[15] Fasciculus Chemicus, abstrusæ Hermeticæ Scientiæ ingressum, progressum, coronidem, verbis apertissimis explicans. Moscow, 1629, 12mo. Dr. Dee was born in 1579 and was educated at Westminster and Oxford. He was a friend of Sir Thomas Browne, who says of him: "He was a persevering student in hermetical philosophy, and with the highest asseverations affirmed that he had 'ocularly, undeceivably, and frequently' seen projection made in Bohemia." He died in 1651.

Digitized by Google

weakness of the system then prevailing, under which all the medical knowledge in the country was concentrated in the hands of a few foreigners immediately about the Court, while the whole of the nation was left without any instructed medical aid whatever. He not only saw the weakness of the system, but he also saw the remedy. In 1692 he tried an important experiment. He sent one of his own subjects abroad to receive a medical education at a foreign university. The experiment was quite successful. The student chosen was one Peter Vassil'itch Postnikof, the son of a *diak*, or Secretary of State, who had also served as ambassador at foreign Courts. Postnikof went to Padua and returned in four years' time with the doctorates of philosophy and medicine of that famous seat of learning. His first appointment on his return was, however, not a medical one, but that of interpreter in the suite of Russian ambassadors at foreign Courts on account of his knowledge of Latin, French, and Italian. He finally returned to Moscow in 1701, and received some medical appointment (probably in the *Prikaz*) worth 500 roubles a year, but unfortunately he died very soon after. The success of Postnikof induced the Czar to send a second Russian student to Padua—this time at the request of the student's father, who was also a *diak*. Gregory Ivanovitch Volkof obtained his degree, returned to Moscow, and, like Postnikof, was employed as interpreter in the diplomatic service. Peter set him to translate the Jardinage of Quintigny, a French book then much in vogue; but whether as a result of the dull character of the book, or on account of the difficulty of translating it, he fell into a melancholy, and so disappears from the stage of history.

And now, having satisfied himself as to the capacity of his subjects to learn the mysteries of medical science, Peter determined to try a much more important experiment, no less than the foundation of a medical school in Moscow, so that students could obtain the needful education without leaving their own country. The first step towards this end was to build a hospital. Before this time there were no true hospitals in Russia. Institutions which passed for such were really rather infirmaries for the aged and disabled than hospitals proper. It is, however, worth noting that late in the seventeenth century, just before Peter's time, the modern idea of a clinical hospital is almost exactly expressed in a ukase from the Czar Feodor to the *Aptekarski Prikaz*. In this the object of hospitals is defined as "to provide the truly poor man with a means of curing his disease; to assign to hospitals until death those with incurable disease ..... to root out mendicants and those who feign sickness," and as a subsidiary object to provide young medical men with a means of perfecting themselves in the practice of their profession.

The hospital projected in this ukase was apparently never built, and the first institution of the kind in Russia was undoubtedly the Moscow *gofshpital*, the construction of which was begun by order of Peter the Great in the year 1706. It was built in a year; and in 1707 was inaugurated, not only the first hospital, but also the first medical school in Russia. Peter had visited England in 1698, and it is supposed that the new building in Moscow was a copy of a hospital he had seen in Greenwich. It was built from the plans of Dr. Nicolaus Bidloo, a Dutchman, who came to Moscow in 1703, under contract to act for six years as *leib-medik* to the Czar. This really able physician and organiser, who gave himself heart and soul to the task of floating the new institutions, was a son of the famous anatomist of Leyden University, and nephew of the no less illustrious botanist of Amsterdam. Bidloo soon became one of the Emperor's most intimate and familiar friends, but, like many others who were in the service of that energetic and exacting person, he found his health unequal to the strain of constant attendance upon his master, and he had been scarcely a year in Moscow when he became really ill. It was then that Peter asked him to design the new hospital and a medical school to accommodate fifty students—a task which Bidloo most willingly undertook.

It is impossible to more than outline the fortunes and misfortunes through which the hospital and school passed. The building itself—the school and hospital were one—being of wood, was utterly destroyed by fire on more than one occasion, but it was always rebuilt, though not always without grumbling on the part of the ecclesiastical authorities who had to find the funds. For the traditional sentiment which regarded the treatment of the sick poor as a duty of the monastic world was still of sufficient force to induce Peter to lay the burden of building the new hospital on the Monastic *Prikaz*, and of rebuilding it after the fire in 1722 on the Holy Synod—the successor of the Monastic *Prikaz*.

The history of the hospital during the first fifty years of its existence is one of constant difficulties with the church authorities, who grudged the expenditure on an institution over which they had no direct control, from which they derived no benefit, and which was used almost entirely for sick and wounded soldiers. They argued, not without reason perhaps, that the military, rather than the ecclesiastical, authorities should bear the expense. The hospital suffered accordingly. The doctors complained of the shocking state of repair of the buildings and want of room for their patients. The Synod refused to give any more funds and referred the doctors to the Senate; the Senate replied that the Synod, as the direct successor of the Monastic *Prikaz*, which had paid for building the hospital, was bound to maintain it. And so between Synod and Senate the buildings slowly went to ruin. At last, however, the Synod gained its point, and in 1754, on the same day that the Empress Elizabeth signed the ukase founding the University of Moscow, the hospital and medical school passed over to the Military *Collegium*—the War Office of the period. Meanwhile, the *Aptekarski Prikaz* had undergone a series of changes and reformations. In 1672 its name was altered—it became the *Aptekarskaia Palata* or Chamber; in 1714 the word Chancellery was substituted for Chamber; in 1725 it was again re-named the Medical Chancellery; and finally, in 1763 in the reign of the Empress Catherine, it became the Medical *Collegium*. Under Peter the Chancellery, which was removed to the new capital on the Neva in 1712, had as its head an official known as the *Archiater*, reviving an old Roman title.[16] The first *Archiater* was a Scotchman, Dr. Robert Erskine; he lived in St. Petersburg, and apparently scarcely knew of the existence of the new medical school and hospital in Moscow. Neither he nor his successors ever visited it, although some of them seem to have watched its work, for they sometimes blamed Bidloo for the slowness with which his students passed through their curriculum. They also to some slight extent controlled the school and its diplomates, whom they drafted off to the army and navy as fast as they could qualify.

The Medico-Chirurgical School, as it was called, was in the meantime slowly getting under way. There were many difficulties to overcome, and the full complement of fifty students was not reached until 1712, five years after the school was opened. The Russians hesitated to send their sons to what they naturally regarded, with many other of Peter's introductions, as at best an outlandish institution, entirely out of keeping with their customs and ideas. But, as has already been seen, a medical career at that time was very lucrative and honourable, and if the Russians themselves at first held back, the foreigners settled in Moscow and St. Petersburg were by no means unwilling to send their sons to Bidloo for a medical education. Ignorance of the Dutch language was no obstacle, for Latin seems to have been the language employed in the hospital and school, and Latin was freely taught in the boys' schools in Peter's time.[17]

Of the internal economy of the medical school and the life of its students some details remain which are not without interest. The students lived in the hospital buildings, occupying thirty-two small rooms on an upper storey, technically called *bourses*. They were divided into three groups according to seniority. They were provided not only with board and lodging, but also with stuff for their clothes. Each boy received seven *arshines* (about five yards) of cloth every two years to make his *caftan*, or long outer coat, his *camisole*, and trousers. Students of the first class received a better sort of cloth than those of the second, and these than those of the third. No mention is made of linen or underclothing, but each student received a rouble a month in coin, and this sum, small though it may seem, probably had to cover the purchase of linen as well as all other small household or private expenses. The students attended the hospital early each morning, and later in the day came the lectures, or "*collegia*" as they were called. The lectures appear to have been mere dictations which were learned by heart, word for word. The dearness, and sometimes the entire absence, of

[16] The title *Archiater* was first given by Nero to his Imperial body physicians. Later to the *Archiatri Palatini* were added the *Archiatri Populares*. See Haeser's History of Medicine.

[17] Even Peter's father, the Czar Alexis, is said to have known Latin and to have read without translation the memoranda of his body physician, Dr. Blumentrost, which were written in that tongue.

Digitized by Google

paper on which to take down the lectures are worthy of mention as an index of the innumerable difficulties which must have blocked the way for the introductions and development of the sciences in those days. The curriculum included quite a wide range of subjects. There was clinical instruction, including the principles of bandaging and surgery. Anatomy was taught; Bidloo wrote a book on the subject and published a splendid anatomical atlas, with illustrations engraved on copper.[18] Peter, as is well known, purchased the famous anatomical museum of the Dutchman Ruysch for 30,000 gulden.[19] Post-mortem examinations were practised, sometimes with a medico-legal object. *Aptekarskaia Nauka*, or the Apothecaries' Science, included botany, pharmacognoscy, pharmacy, and pharmacology. The London Pharmacopœia seems to have been used. Operations were performed on the living and dead. Trephining must have been frequently performed, to judge by its constant appearance as the subject of examination questions at that time. Bidloo was an autocrat like his employer Peter. He had absolute power over everything and everybody in the hospital and school, and very severe punishments were sometimes meted out to the erring student. The severest were imprisonment on bread and water, fettering, beating with the knout, and finally—only for the worst offences—expulsion from the school to serve in the ranks of the army. Drunkenness and brawling seem to have been not infrequent, but they were most strictly punished. The course of instruction varied in length from five to seven, or even to ten, years. The comparative length of the curriculum was due to the conscientiousness of Bidloo, who would not grant to any student a diploma until he was thoroughly qualified, notwithstanding that Peter offered a high premium upon every student who passed. The first issue of diplomas was in 1713, and others followed in 1718, 1723, and 1727. The examinations for the degrees, of which there were two, those of *lékar* and *pod-lékar* (or *sub-lékar*),[20] took place in the presence of all the teachers in the school and of medical men from the outside as well.

Such, in brief, is the picture of Russia's first medical school. Not, some will say, a very attractive or striking picture when contrasted with that of a modern medical school; but when the circumstances of the time are taken into consideration, and more especially the material difficulties to be overcome, the prejudices to be soothed away, and the ingrained habits and views of a whole people to be entirely transformed and turned into totally new channels, it becomes a matter for wonder that so much was accomplished in so short a time. An equally detailed picture might be given, did space permit, of the hospital as of the school—not perhaps of its very earliest days, but as it was in 1735. That year was an epoch in its history. Bidloo, its founder and organiser, died. The Empress Anna was on the throne, and on the petition of the then *Archiater* of the Medical Chancellery the hospital came under the supervision of that body. In the same year was published the "General Reg'ament concerning Hospitals," an Imperial law which was binding, not only on the Moscow Hospital, but on the other institutions of the kind which had already been built in different parts of the country. From this remarkable historical document it is possible to see the entire organisation of those early, but by no means primitive, institutions. From it may be learned the numbers and duties of the doctors and *lékars* of various grades, of the clerical staff, the dispensers, male attendants, laundresses, cooks, gardeners, brewers, and others attached to the hospital staff; the diet of the patients (by no means an ungenerous one) may be studied in detail, as well as the modes of ventilation and lighting, the nature of the beds and bedding, and many another point of interest, while incidentally something may be gathered as to the commonest modes of treatment then in vogue. On paper the picture is that of a well-ordered, well-organised, and liberally supplied hospital. In practice—at least, in the case of the Moscow Hospital—it is to be feared it was not quite so perfect, and it will be convenient here to follow very briefly the fortunes of that institution until it lighted on better days at the very close of the last century.

The hospital under the Medical Chancellery was in no way better off, perhaps was not so well off as under the immediate direction of Bidloo, while as regards the sinews of war the military authorities proved to be far less liberal than the Holy Synod had been. For a time, with an able administrator like Baron Tcherkasof at the head of the Chancellery, it prospered; but after his day the whole establishment slowly went to ruin. And this was equally the case with the hospitals which had been built in other Russian towns—in St. Petersburg, Riga, Elizavetgrad, Kherson, and Kief. When the Emperor Paul came to the throne in 1796 it is said that there was not a hospital in the country in which 200 patients could be safely placed; there was not a ward which did not let in freely both the wind and the rain; and the hospitals were terribly overcrowded, two patients being constantly placed in one bed. Paul visited the Moscow Hospital soon after his accession and was horrified at its condition—so horrified that he at once ordered its re-construction. This was commenced in 1797, and the new building, with room for 1280 patients, was completed in 1802. A sum of half a million roubles had been assigned for its cost, but the amount expended was something over 650 000 roubles. When the present Army Medical Academy was founded in St. Petersburg in 1799 the Moscow Hospital ceased to be used for clinical instruction. It became a purely military hospital, and as such it exists at the present day. The existence of other Russian hospitals in the last century has just been referred to. It is unnecessary here to mention more than one or two of these institutions. The most important were naturally those in the new capital of St. Petersburg and the adjoining fortress-island of Cronstadt. The St. Petersburg Admiralty or Naval Hospital was solemnly opened by Peter the Great in 1716. Its position was close to that of the present large clinique of the Army Medical Academy. The Dry-land Hospital, *Sukhoputnui*, so called in contra-distinction to the *Morskoi*, or Naval Hospital, was founded in 1717. It was rebuilt after being burnt down in 1733, and in that year three new medico-chirurgical schools were instituted, one at each of the St. Petersburg hospitals and one in Cronstadt. From that date all hospitals devoted to clinical instruction were termed *generalnui*, or general hospitals.

In Catherine II.'s memorable reign quite a number of new hospitals were built. In Moscow she founded the still existing Catherine Hospital, at first intended only for the purposes of small-pox inoculation, but later turned to more general uses; the Pavlovski Hospital, named after her son, who succeeded her as the Emperor Paul; the Golitzin Hospital, and a lunatic asylum. In St. Petersburg the Obukhovski Hospital—which still exists and is one of the largest of the municipal hospitals in the city—was founded in 1784. A lunatic asylum was founded in the same year. Nor must omission be made of the hospitals or asylums characteristic of the period which the Empress opened for the treatment of secret contagious diseases. At first these seem to have been merely private houses in which patients of the upper classes were received, the utmost secrecy being observed and no questions asked as to the name or rank of the individual. It is worth noting that almost at the same time as the ukase was issued instituting these homes another ukase was signed in which strict orders were given, in the case of soldiers affected with these diseases, to make close inquiry as to the source whence they had acquired it. In 1763 was opened a hospital called the "Secret Hospital," with beds for thirty men and thirty women, and in this, as in the home just mentioned, absolute secrecy prevailed, the very linen being marked with the single word "Discretion."

Another group of institutions no less characteristic dates from the great Empress's reign. Few of those who attend the approaching International Congress in Moscow will fail to visit the famous Foundling Hospital on the banks of the River Moskva. It has long been regarded as one of the "sights" of the city, and is certainly well worth a visit. It is both the largest and the oldest hospital of its kind in Russia, dating from the year 1764. The Foundling Hospital in St. Petersburg scarcely yields to it in size, and is only six years its junior, as it was opened in 1770. These institutions were founded by Catherine with the laudable object of providing a refuge for unfortunate women in child-birth and of saving the lives of the no less unfortunate children they brought into the world.

[18] Positionum Anatomo-physiologicarum. Parts I. and II., Ludg. Batav.

[19] Ruysch wanted 50,000 gulden for the secret of his mode of preparing anatomical specimens, and refused to tell it to Erskine for less. He seems, however, to have divulged it to Peter, who told it to Blumentrost, and after passing through one or two more hands it was published by Rieger, another foreign *leib-medik* at the Russian Court.

[20] The title of *lékar* still remains. All persons qualified to practise must have the diploma of *lékar*; the higher degree of Doctor of Medicine is optional. The degree of *sub-lékar* was done away with in 1799.

VI.

The Leading Russian Practitioners of the Eighteenth Century.

IT will be noticed that the history of medicine in Russia has already become more a history of institutions than of individuals, such as it had for the most part been before Peter the Great's time. The names of certain individuals, however, still stand out with sufficient prominence to demand brief special notice. But it will be convenient first to note shortly what can be gathered as to the conditions of medical practice in Russia in the last century. So far as the bulk of the people was concerned, it would seem that for the greater part of the century they were little better off for medical aid than in the earlier periods The hospitals already described were almost entirely filled with soldiers and sailors. The large majority of medical diplomates from the newly founded schools were drafted off to the ever-growing army and navy. Most of them, too, it must be remembered, were still foreigners, and were mistrusted by the peasantry, who preferred their *znakhars* and *znakharkas*—the "wise men" and "wise women" of the village. Travelling charlatans, popularly known as *Vengertzui*, went about the country and did a thriving trade in pills and potions. They became so numerous that Dr. Blumentrost in 1721 applied to the Senate for a special law against them. It was in that year that he drew up a scheme for the institution of a Medical *Collegium* on the lines of the other *Collegia*, as the Ministries had then come to be called, which should have the entire control of all medical affairs in the empire. Only two of the numerous points in the scheme became law. One of these was to the effect that qualification should be necessary for practice, but though it became law it seems to have remained to a great extent a dead letter.

Of the leading medical practitioners in Russia in the last century the oft-quoted name of Dr. Bidloo must unquestionably occupy the first place. He was the real founder of modern medicine in Russia, for before his time all medical practice was in the hands of foreigners, and it was he who led the way in training the Russians themselves to the medical profession. The second place should probably be assigned to Lawrence Blumentrost the younger. There were three Blumentrosts in Moscow in Peter's time—a father and two sons. The elder Lawrence, a Dutchman, died in Moscow in 1705, before the opening of the medical school. Both he and his eldest son John left less mark upon their time than the younger son Lawrence, who was born in Moscow, and sent by the Russian Government to Germany and Holland for his medical education. Having graduated at Leyden he returned to Moscow and became *leib-medik* to Peter. Many years later he was appointed to the full charge of the hospital. Of the many successive holders of the position of head of the Moscow Hospital, only one other must be mentioned here. Dr. Athanasius Shafonski, a Russian, was appointed in 1769, and in the following year the famous plague of Moscow broke out—one of the worst pestilences perhaps ever known in any city. Shafonski, in his position as head of the hospital, had ample opportunities of studying the disease and he has left an admirable description of it, both from the medical and historical point of view, in a book, now rare even in Russia, which was published by Imperial command in 1775.[21]

Other Russian names which have survived are those of Poletika, a native of Kief, who ultimately became professor in the University of Kiel—the first Russian who obtained a foreign medical chair; Ambodic,[22] a famous accoucheur, head of the Obstetrical Institute, who first introduced the use of the forceps into Russia, and who published the first Russian work on obstetrics; and Shchepin, who taught anatomy and surgery first in Moscow and then in St Petersburg. Baron Tcherkasof, though not a qualified medical man, had attended medical lectures when in England, and ultimately became president of the Medical *Collegium* in Moscow. It was owing to his exertions that in 1764 a medical faculty was added to the University of Moscow, which had been founded ten years previously. The new faculty, however, did not for many years grant degrees. The Medical Chancellery or *Collegium* was still the sole source of licences to practise, and it was not until 1794 that the first medical degree was conferred by a Russian university.[23] Tcherkasof was distinguished for his patriotism, amounting sometimes almost to Chauvinism. This was shown particularly in his relations to the foreigners, who still predominated in the Russian medical hierarchy. His endeavours were constantly directed to the replacing of them by his own countrymen; and on one occasion he went so far as to induce the Medical *Collegium* to issue a ukase, declaring that foreign doctors were no longer needed now that Moscow had a degree-granting University of her own. The ukase, however, met with a very cold reception and was never acted upon. Tcherkasof's patriotism did not prevent him from loyally coöperating with the famous Dr. Dimsdale, whom, at Catherine's command, he invited from England. Dimsdale was then the greatest authority living on the subject of small-pox inoculation. The story of his inoculation of the Empress herself and the Czesarévitch has been so frequently told that it may be very briefly recapitulated here. It was in 1768 that Catherine sent for Dimsdale, whose writings had already made his name famous. He went to St. Petersburg, and is said to have passed two months in making preliminary experiments before inoculating his Imperial patient herself. When the time came the greatest secrecy was observed. At 10 o'clock one autumn night a carriage drove up to a side door of the Winter Palace, and from it descended Dr. Dimsdale and the Czesarévitch (afterwards Emperor) Paul Petrovitch, the latter carrying under his furs an infant who was to furnish the material for inoculation. On the following day the Empress retired to Tsarskcé Selo, where she passed through the subsequent malady "with great firmness of mind." A little later Paul was himself inoculated, and when these facts were made public it soon became the fashion in St. Petersburg to be inoculated. The infant from whom Catherine had been inoculated was christened Ospennui, from *ospa*, small-pox He was made a Court page and granted a patent of nobility, the crest on his coat of arms being a child's arm bearing a large pock-mark, which was perhaps more appropriate than beautiful. He died young, however, and the coat of arms was never borne by anyone but himself. Dimsdale received high honours from the grateful Empress. He was created a Baron, received a large sum of money and

handsome presents, and was further rewarded by a pension of £500 per annum for life.

To return for a moment to the reign of Peter the Great, the name of Robert Erskine, already mentioned, deserves some further notice. A graduate of Oxford and a Fellow of the Royal Society, Erskine, or, as the Russians re-christened him, Areskin, went to Moscow in 1706 as physician to Prince Menshikof, and it was he who recommended him to Peter. Peter appointed him his *leib medik* in 1713, and three years later he became, as was stated earlier, the first *Archiater* of the Medical Chancellery. He travelled with the Czar through Germany, Holland, and France, and it fell to his lot to formally propose Peter for the Membership of the Paris Academy of Sciences. In the famous anecdote which relates how Peter was present at, and took great interest in, an operation for cataract performed in one of the Paris hospitals, it was Erskine who was the operator. He was a relation of the Earl of Mar, and—with how much truth need not be discussed here—was charged by his enemies in England with holding treasonous correspondence with the exiled Stuarts. He was able, however, to refute these charges to the Czar's complete satisfaction, and he remained in Russia till his death in 1718. He died at Olonetz, where he had gone to take the baths, and his remains were honoured by a magnificent funeral in the Alexander Nevski Monastery in St. Petersburg, the Emperor himself following in the funeral procession. Throughout the century the names of many other English medical practitioners in the Russian service may be met with. Lewis Calderwood went to Russia in 1728 as surgeon to the famous Preobrajenski Guards; he later held appointments in the Moscow and St. Petersburg Hospitals, and died in 1755 Matthew Guthrie obtained the right to practise in Russia in 1769 Robert Simpson joined the great Admiral Greig's fleet in 1774 and in 1792 became chief surgeon to the large Naval Hospital in Cronstadt. Charles Brown, an Aberdeen graduate, obtained the Russian diploma in 1784, and Samuel Hurst, a Cambridge graduate, obtained it two years later. Henry Holloway was surgeon to the Finnish Army in 1788; Charles Stewart was attached to the troops in Poland a little later. Jonathan Rogers was surgeon to the fleet in 1771; he also accompanied a Russian Embassy to Constantinople, and was later surgeon to the Izmailovski Regiment. He returned to England in 1799, but was again in Russia in 1803 and from that date to 1811 was general staff-surgeon to the fleet. In 1806 he published his Russian Naval Pharmacopœia.[24]

A more diligent inquiry into the records of the time would doubtless bring to light many another name which might well be added to the list. But those here given will suffice for the present purpose, with the addition of but one more, that of Dr. John Rogerson. A native of Dumfries-shire and a graduate of Edinburgh, he went to Russia in 1766 and remained in that country for just fifty years. For most of that time he was *leib-medik* to the Empress Catherine and her successors. He was with the Empress in her memorable progress throughout her realm in the year 1787. The famous De Ségur, the French ambassador, who also shared in the progress, has left a lively description of this journey in his "Souvenirs et Anecdotes." The Scotch doctor was apparently somewhat deficient in a sense of humour, for, according to De Ségur, he was on one occasion seriously offended by a very harmless and ancient jest on the part of the Frenchman. Catherine had at one part of the progress presented Dr. Rogerson with a magnificent sword in recognition of his services. The opportunity for an obvious sally was too good to be missed by the volatile ambassador. "Docteur," he said, "je vous en félicite; vous avez là une nouvelle récette, sûre et expéditive." Dr. Rogerson's name is also enshrined in a couplet written by the Empress on the death of a favourite dog:—

"Ci gît la 'Duchesse Anderson'
Qui mordit Monsieur Rogerson."

Catherine was assuredly no poetess. A brief account of the French Lestocq, whose wonderful career, however, belongs rather to political than to medical history, closes these notes on the medical celebrities in Russia in the last century. The son of a member of the French Reformed Church who had settled in Hanover, he is described as "a man wholly destitute of political qualities, without discretion, and without connexions." But notwithstanding these deficiencies it was he who guided the revolution which in 1741 placed the Empress Elizabeth (the daughter of Peter the Great) on the throne of Russia. The Empress in return made him her *leib-medik*, and granted him estates and orders and other honours so long as he remained in favour. But those were the days of rampant favouritism, when nothing was certain but the uncertainty of Imperial sunshine, and when nothing was more common for those who had basked in it for a time than to fall in a day—just as many of them had risen the reverse way in a day—from the top to the bottom of the ladder of fortune—to pass from the luxuries of a palace in St. Petersburg to the prospective horrors of an *ostrog* at the mouths of the Obi. Such was Lestocq's fate. He kept the Empress's favour for some seven years, but in 1748 the almost inevitable downfall came. He was exiled to Siberia and never returned.

VII.

The Opening of the Present Century; the System of Tchins or "Ranks."

WITH the close of last century and the opening of the present a new era began in medicine, as in most other things in Russia. The Empress Catherine had died in 1796 after a reign of thirty-three years. The erratic Paul, who succeeded her, came to an untimely end in the gloomy palace in St Petersburg, which still bears his name, in 1801. His reign is noteworthy if only for the re-building of Peter's famous hospital in Moscow and for the founding in St. Petersburg of the great Academy of Military Medicine, which will next year celebrate the centenary of its existence. But the accession of Alexander I, the son of Paul, was a real epoch, from which the Russia of to-day may in some sense be said to date. The new Emperor had not been many months on the throne before a vast series of reforms was instituted, affecting almost every individual and every interest in the empire. With these it is not proposed to deal here, except in so far as they touch upon matters relating to medicine. And, first, it is of interest to note the recognition given to such matters under the new *régime*. The *Aptekarski Prikaz*, the first medical department of the Government, has already been traced through its various changes of title until it became the Medical College in 1763. As such it remained for the rest of the century, though, so far as may be gathered from the records of the time, its influence during the latter half of the century was but small. But the already existing organisation of this body, such as it was, was taken advantage of by the framers of the new Ministry or Ministries which were instituted by the famous manifesto of Alexander I., issued in September, 1802. The Ministry, as the new machinery of government was collectively called,

consisted of eight divisions, or what would now be called in Russia, and were even then spoken of as, separate Ministries. Of these, not the least important was the Ministry of Internal Affairs, and it was into a sub-division of this that the old Medical College was incorporated, together with another body which need not be further noticed here.[21] After one or two slight changes this sub-division was re-named the *Expédition* of State Medicine, a title which it retained until, in 1811, it received the title it now bears, that of the Medical Department of the Ministry of Internal Affairs.

Prince Kotchubei was the first head of this Ministry, and it was under his direction that a scheme was framed for the institution of another very important body, which, as the Medical Council, has since become the highest medical authority in the land. In its original conception the Council was framed on the lines of an ordinary learned society, but was to be regarded as a sort of consultative body, in which all the best medical learning of the time should be concentrated, and to which the Government could at any time appeal for advice or decisions on questions relating to medicine and those who practised it. It consisted of an indefinite number of members appointed by the Ministry, and these might be foreigners as well as Russians; but all were men distinguished by their medical knowledge and of high general reputation. The dean, or president, was elected by the members for three years, and there were corresponding members, a scientific secretary, and two interpreters attached to the Council.

It will be seen that as early as the beginning of the present century there were in Russia two governmental medical bodies—the *Expédition* of State Medicine and the Medical Council, both attached to the Ministry of Internal Affairs. These two authorities still exist in scarcely altered guises—the first as the Medical Department, the second still as the Medical Council. It would serve no useful purpose here to enter in detail into their functions or the relation they bear to each other. Suffice it to say that that relation was clearly defined. Briefly and in very general terms the functions of the Council were those of a legislative and the functions of the *Expédition* those of an executive body, the division of responsibilities between them being much the same as it is between the corresponding authorities at the present day. The further history of the two central medical authorities until they assumed the form they now have is soon told. In 1810 a considerable number of matters of medical interest came under the Ministry of Education, but only for a time. In 1811 another great change was made in the organisation of the Government, as the result of which a classification of Ministers was introduced, which, with some slight alterations, has remained down to the present day. Though not perhaps bearing directly on the present subject-matter it may be of interest to some readers to state briefly what that classification was and is.

In 1811 the governing authorities were grouped into five divisions, each of which contained one or more Ministries as follows:—1. *External Affairs:* Ministry of Foreign Affairs. 2. *External Safety:* Ministries of War and Marine. 3. *State Economy:* Ministries of Finance, Internal Affairs, Education, and Ways and Communications. 4. *Justice:* Ministry of Justice. 5. *Internal Safety*, Ministry of Police. In addition there was, and still is, an *Upravlénié* (Board of Direction) of foreign religious creeds. Since that date these nine Ministries have become ten, two new ones having been added and one having disappeared. The Ministry of Police was, after a few months' separate existence, absorbed into that of Internal Affairs. The two new Ministries which exist now and did not then are those of the Imperial Court and of Agriculture and Imperial Domains. It was under the new classification of 1811 that the Medical *Expédition* became, what it has ever since been called, the Medical Department, then, and for a few months after, of the Ministry of Police, now of the Ministry of Internal Affairs.

A word may be said here about another department and its curious growth from small beginnings to a useful and important part of the same Ministry. As early as 1804 Prince Kotchubei had felt the want of properly recorded statistical facts and conclusions based thereon, and at his suggestion a small *Obshtchestvo Dvorian* or Literary Society of Nobles, as it was then called, was formed. This consisted of ten members, all highly educated young men of good birth, who undertook, firstly, to keep a historical record of the new Ministry and all the changes it should undergo, and, secondly, to collect and work out all available statistical information about every "government" in the country. In this way it was hoped to gain more or less reliable statistics of the whole empire. The plan, however, did not work very well, for reasons which need not be entered into. But with the re-organisation of the Ministries in 1811 a fresh impetus was given to the movement. It was proposed to form a separate statistical society, but it ultimately took shape as the Statistical Department of the Ministry of Internal Affairs—a name which defines with sufficient clearness for these brief notes its objects and functions. The use of such a department as ancillary to that of State Medicine is obvious.

And now, having traced the two central medical bodies from their early beginnings to their present state, it becomes necessary to give a brief account of them as they now are, of the duties they discharge, and of their relation to each other. The Russian Medical Council is expressly defined in the Imperial Code of Laws as "the highest medico-educational, medico political, and medico-legal authority in the empire." It consists of a president and an undefined number of members. Certain highly-placed medical officials in other departments are *ex-officio* members—namely, the director of the Medical Department of the Ministry of the Interior; the heads of the Army Medical and Navy Medical Departments; the medical inspector of the important group of philanthropic institutions founded by, and bearing the name of, the Empress Marie, the beneficent consort of the Emperor Paul; one representative each of the Ministries of Education and Finance; and some others. The remaining so-called consulting members, *soviéshtchatelnuié tchlenui*, are chosen for their ability and reputation from among the higher ranks of medical *tchinovniks* or officials. The Council meets twice a week and deals with a vast number of subjects, some of which may be briefly noted, but which are too numerous to name in full. First, there is a group of subjects which would naturally be expected to come under the decision of such a body. Such are the censorship of medical publications and advertisements; the issue of orders and regulations in regard to epidemic infectious diseases; the granting to foreigners of licences to practise; the supervision of all medical reports and observations; and the payment of pensions to medical officials. A second group of subjects may be named separately, though the line dividing them from the first is but an ill-defined one. There are matters which, though dealt with by the central authority in Russia, might be, and in some other countries are, dealt with by individual persons or institutions. Of these may be mentioned the investigation of new discoveries in medical science; the analysis of Russian natural mineral waters and instructions as to their use; and the revision of evidence in inquiries into cases of sudden death. All matters are brought before the Council either by the Minister or one of the directors of departments, and a simple majority decides, the president having a casting vote. The president, who must be a medical graduate, is nominated by the Minister and confirmed by the Emperor. At present this important post is held by Professor Pashutin, who is also *natchalnik*, dean or director, of the Imperial Academy of Military Medicine. The Medical Department of the Ministry of Internal Affairs consists of a director, a vice-director, and a certain number of sections, and it deals with a great many different matters which are grouped under the heads of civil medicine in general, legal medicine, and medical police. There is a catalogue of no less than forty-seven such matters, of which obviously only a small minority can find mention here, and as a type may be named the distribution of all qualified medical men, veterinary surgeons, and pharmaceutists who leave the Universities or the Army Medical Academy (the sole licensing bodies, as will be shown presently) and enter the public service. The appointments of all medical *tchinovniks*, or officials, whether in towns or *uyezds* (districts), whether to the local governing bodies (the *zemstvos*), to mineral spas, to the police, to quarantines, factories, or any other institution which comes under the civil administration, as well as their remuneration and removal, are in the hands of the department. In addition, all civil hospitals, all druggists' shops and druggists, and all certified midwives are under its more or less direct control, as are public vaccination, the carrying out of measures to check epidemics, and the tabulation of statistics of disease and mortality throughout the empire. These are a few of the subjects with which the

[21] This was the *Prikaz* of Social (or Communal) Supervision, which was a sort of Board of Charity Commissioners, and which did, and still does most useful philanthropic and charitable work.

Digitized by Google

department has to deal. The present holder of the responsible post of director of the Medical Department is Dr. Lev Ragozin. The department publishes a monthly journal called the *Messenger of General Hygiene and Legal and Practical Medicine*, a magazine which, in addition to the official statistics and announcements of the month, contains a large number of original articles and of references to foreign current medical literature. An annual report of the department is also issued. This contains the illness and mortality statistics of the whole empire—a vast mass of figures arranged in elaborate tables—and also the returns of the vaccination stations and the other numerous institutions, some of which have already been named, under the department's jurisdiction. The report is rather larger than our own Registrar-General's annual report. In addition to the Medical Council and Medical Department, the Ministry of Internal Affairs has attached to it a Veterinary Committee, under whose control are all matters connected with disease in animals.

In the course of this chapter the Russian word *tchinovnik* has occurred more than once. It has on each occasion been translated as "official," but a few words of explanation may perhaps make the exact meaning of the term more clear. It must be premised that the whole machinery of administration, whether central or local, is in the hands of a body of officials, who form collectively, perhaps, the largest and most powerful bureaucracy in the world. The system may be roughly conceived as a triangle, with the Chancellor of the Empire, in the first class, at the apex, and each successive rank containing more and more individuals. The *tchinovniks* are divided into fourteen ranks or *tchins*, each rank, whatever the profession or calling of the individual, corresponding with some rank in the military and naval services. The whole system of *tchins* dates from the time of Peter the Great, whose object in instituting it in 1722 was a laudable one. In his day there was but one class of nobles—those whose sole claim to nobility was that of heredity, a heredity untempered by the law of primogeniture—with the result that the most remote descendant of a "noble" still claimed nobility, to whatever walk of life he had actually descended. It was Peter's object to replace this class of nobles by another whose claims should be those of real service done to the State or to the Emperor. In this he did not succeed, as the old class of nobles with the old form of heredity still remains, but he succeeded in adding to them a new class of nobles. This he did by decreeing that among civil officials, or *tchinovniks*, as they were henceforth called, the first four ranks should confer hereditary nobility, and those from the fifth to the ninth personal nobility. In the army and navy the hereditary nobility was conferred by the first six *tchins*, and personal by the last eight. The preference given to the army and navy is thus seen in the fact that in them all the fourteen ranks carried nobility with them, while this is the case with only nine out of the fourteen civil grades.

Those who are curious in such matters may be interested to know that a doctor of medicine belongs to the eighth *tchin* (that of *Assesseur de Collége*); that he ranks with a major in the army and a lieutenant-captain in the navy, and is entitled to be addressed as "*Vashé Vuisokrodié*" ("*votre haute-naissance*"). A *lékar*, on the other hand, or holder of the lower medical qualification, only ranks with a captain in the army and a lieutenant in the navy, and is addressed as "*votre haute-bonne-naissance*" only—a longer title, but one conferring less honour on its recipient. A university student, who must have passed out of one of the State *gymnasia*, has already his foot on the ladder of ranks as a member of the fourteenth class. And it is open to the medical man to rise to almost any rank. His services to the State may be rewarded by the honorary title of Privy Councillor or Actual Privy Councillor, titles which raise the bearer to the third and second ranks respectively. Or he may receive from the Emperor some decoration which will give him an almost equally high position. Mere length of service, too, entitles the Government medical official to a rise in rank; thus, after four years' honourable service he would rise one step higher than that he had previously occupied; but the highest *tchin* attainable in this mechanical way is that of Privy Councillor, which occupies the third class in the table of ranks. Service in more remote parts of the empire, such as Siberia or Central Asia, entitles to a quicker rise, two days counting as three, or three as four, as the case may be. But to enter into all the intricacies of the great system of *tchinovnism*, even only so far as they affect medical men, is an absolute impossibility. The laws and regulations relating to it fill a volume of themselves.

VIII.

The Medical Bureaucracy in Russia.

IT will be convenient here to give a brief sketch of the medical bureaucracy as it now exists in Russia. Naturally the highest places are occupied by the two central authorities just described, the Medical Council and Medical Department. Many other central institutions, such, for example, as the Medical Chancellery of the Ministry of the Court, the Medical Faculties of the Universities and the Army Medical Academy, the medical officers to the "Institutions of the Empress Marie,"[26] and the Medical Departments of the Army and Navy, fill high positions, as so also do the physicians or *leib-mediks*, surgeons or *leib-chirurgs*, and specialists appointed to the Imperial family. It is not, however, proposed to consider these here. Here we propose to give a brief outline of the public medical service—that is to say, the service which in town and country is responsible for the public health of the people and for free medical aid to the poor. In no other nation is the distinction between urban and rural communities so marked. The towns are separately considered by the law from the country; so that every town has its *golova*, or mayor; its *duma*, or town council; its *vprava*, or executive board; and to these and the police are entrusted the organisation of a sanitary service and the provision of hospitals and dispensaries for the poor. The details of the law are not the same for all parts of the country, and some large towns, more especially the capitals, have entirely distinct organisations of their own in this respect. Both Moscow and St. Petersburg may well be proud of their immense municipal hospitals and dispensaries and of their public health services, which have done so much, and are still doing so much, to provide for the sanitary needs of these rapidly growing cities. It may be asserted without hesitation that some of these hospitals[27] will prove veritable revelations to many foreign visitors to the International Medical Congress, whose knowledge of Russia and her institutions may be of that vague and inaccurate, even if not prejudiced, nature which is but too common.

With this reference to urban resources, we pass to a subject which is in some respects of greater interest, as it presents many points more characteristic of the nation—that is, the public medical service in the country districts, and more particularly among the peasants, who form so large a majority of the population. To make this quite clear a brief account of the system of local administration which prevails in Russia is absolutely essential. It shall, however, be as short and concise as possible.

The whole country of Russia (or so much of it as is not under military rule) is divided for administrative purposes into "governments" (*gubernii*) and "provinces" (*oblastui*). Each[28] of these, again, is divided into "districts" (*uyezds*), which are again sub-divided into "towns" and "rural *volosts*"—a *volost* being made up of an indefinite number of village communes or *mirs*. Now each of these divisions and

[26] These institutions have already been briefly referred to. The Russian empresses and princesses have ever been, and still are, foremost in promoting good works of all sorts, and those of two sorts they have taken under their special protection—namely, institutions devoted to charity in any form and those connected with the education and interests of women. It is just a hundred years since, in May, 1797, the Empress Marie, the wife of Paul, took, with the Emperor's consent, all such institutions under her immediate patronage, and each succeeding empress has shown the greatest interest in the welfare of the "Institutions of the Empress Marie," as they have ever since been called. Only a very few of these can be named here. Among those devoted to charity may be mentioned the immense Foundling Hospitals in St. Petersburg and Moscow, hospitals, orphanages, and refuges for the poor of all kinds and descriptions; and among those devoted to the interests of women, the Xénia Institute in St. Petersburg and a vast number of schools and *gymnasia* for girls in all parts of the country. There are in all 539 charitable and educational institutions under the board of management (which is practically a Government department in itself). The voluntary subscriptions received during the past fifteen years have amounted to over 12,000,000 roubles, equivalent to an annual sum of 800,000 roubles, or over £80,000.

[27] And not only the hospitals, but the many other medical institutions, some of which will be described in detail, but many of which must escape mention from want of space. Such, for example, is the Imperial (Oldenburg) Institute of Experimental Medicine in St. Petersburg.

[28] This description applies only to those parts of the country in which the system of *zemstvos* has been introduced. This has now been done in a majority of the "governments" of European Russia.

Digitized by Google

sub-divisions has its governing body. The "government," as the largest division, may be taken first. Each government is administered by a council, or *gubernskoé zemstvo*, an executive board, or *gubernskaia uprava*, and a "committee for peasant affairs." The functions of these bodies need not be considered except in so far as they deal with medical matters. To each government *uprava* is attached a medical board (*vratchebnoé upravlénié*), consisting of a medical inspector and his assistant, a pharmaceutist, a secretary, and a consultative board, to which any number of medical men, even unofficial practitioners, may be added. These medical boards have very considerable powers, and can decide many important medical and sanitary matters without reference to the Central Medical Department, to which, however, they are ultimately responsible. Here are some of their duties and responsibilities. All medical men, whether officials or private practitioners, all *feldschers*, all midwives, all druggists and their shops, and all civil hospitals are under their more or less direct control. In their care is always a sufficient store of surgical instruments which the central authorities provide free of cost, and which the boards are allowed to lend whenever required to any medical man, whether official or in private practice, under, of course, proper guarantee for their return. All medical practitioners in the "government" are by law enjoined to make monthly returns to the board of all cases of illness and death which have been under their care, whether in or out of hospital. As a matter of fact, this injunction is to a large extent not carried out, and in the majority of instances yearly instead of monthly reports are returned, while in many instances, especially in the case of private practitioners, the instruction to return cases of illness as well as of death is not complied with. It might, indeed, be seriously questioned whether such monthly returns of illness would serve any useful purpose, particularly as the returns of acute infectious cases are separately provided for. The Medical Department publishes annually the figures of some 26,000,000 cases of illness which have been registered, but in a population of nearly 130,000,000[29] this obviously does not represent the true totality of sickness. All public health measures, the medical topography of the government, the control of lunatics, in a word, all medical and sanitary matters come under the jurisdiction of the board. The mode of procedure is defined with very great exactitude in the Medical Code of Laws,[30] or by different regulations which have been issued from time to time to cover particular cases. It may be added in passing that the whole medical law of Russia, with these various regulations now collected for the first time and inserted under the paragraph of the law to which they bear reference, is in course of publication. The first of the three volumes to which this great work will ultimately extend has recently been issued and is a model of careful editing. It is unnecessary to enter here into the methods by which the multifarious duties of the government medical board are carried out. It is sufficient to say that the activity of the board is to a great extent concentrated in the person of the inspector, who is directly in touch with, and responsible for, the institutions and individuals under the board's control. As in the case of the board, so in that of the inspector, the law is so worded that the widest interpretations may be put upon the duties of both.

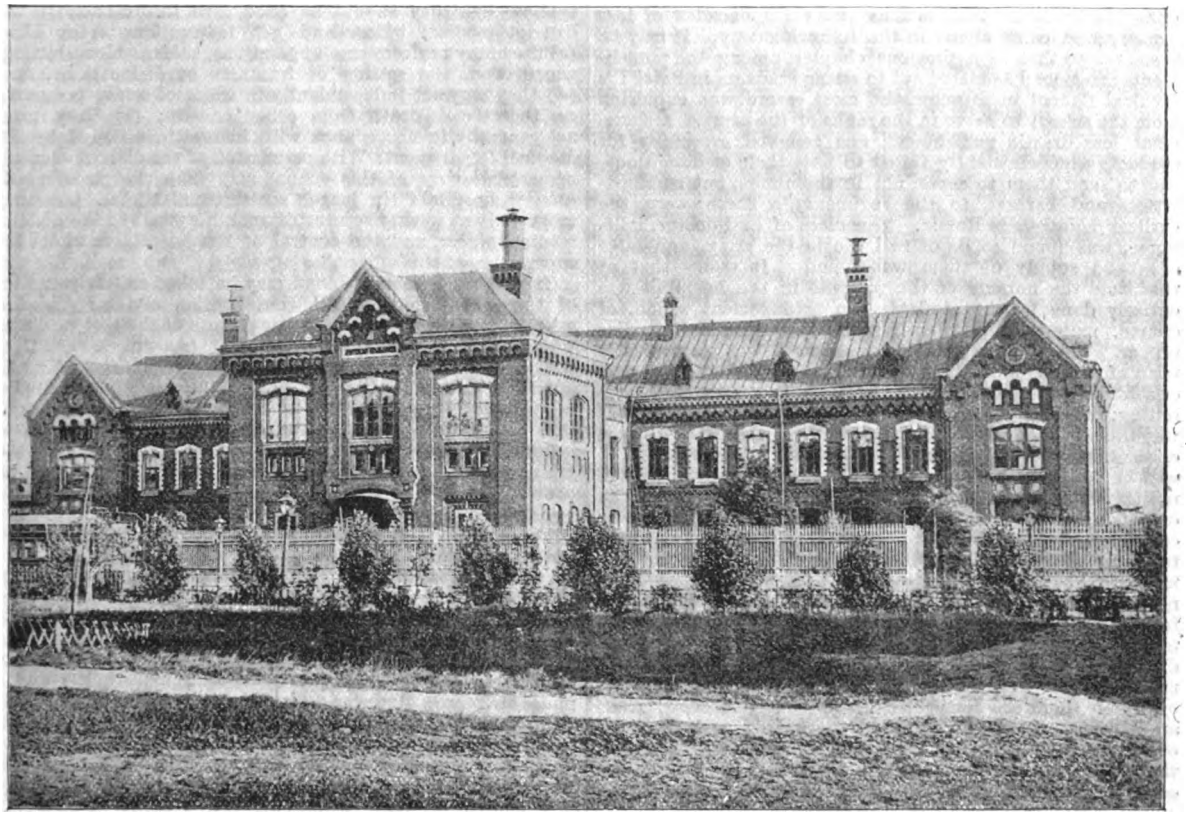
Such, in brief, is the provision made for dealing with medical matters by the "government," or largest division of the land. The next smaller division is the *uyezd*, or district. This is administered by a council or *zemstvo*, an *uprava* or board, and a committee for peasant affairs, just as a "government" is. But the district has no medical board. It has, however, at least one official, *uyezdnui vratch*, or district medical officer, and a certain number of veterinary surgeons and *feldschers*, or trained medical assistants. There are also a committee of public health and a vaccination committee (*komitet obshtchestvennago zdravia* and *ospennui komitet*). The constitution of these two committees is very similar; that of the first may be taken as a type. It consists of the "leader of the nobility" of the district, the *ispravnik* or police commissary, the police master, the district medical officer, the mayor of the town (the capital town of the district), and the senior priest of the district, thus representing a considerable number of different interests and classes of society; other members may be added, such as local estate-owners, doctors, priests of different religious creeds, and so forth. Both the committees work in conjunction with the government medical board, and have immediate control of the sanitary and medical interests of the district.

As already stated, the *uyezd* is made up of a number of *volosts*, these again consisting of a collection of village communes. But lower than the *uyezd* the law does not provide for any medical appointments. The district medical officer is, so to speak, the ultimate unit in the medical bureaucracy, and in view of his responsibilities and of his isolated position in the country the Ministry of the Interior has made provision for a more prolonged course of medical instruction in his case than in that of the ordinary medical graduate. For this purpose a certain sum of money is set aside annually which enables the Ministry to send a selected number of these officials to St. Petersburg or other university towns for further post-graduate study. This is also done in the case of the government medical inspector, who of course occupies a much higher position and one of much greater administrative responsibility than that of the district medical officer. Both these titles are only gained after severe examination in the universities, and both appear in the list of medical degrees attainable at a university, as will be explained hereafter. Few questions have been the subject of more controversy than those connected with this appointment of district medical officer or *uyezdnui vratch* and the duties he has to fulfil. Touching as it does upon economic questions of the highest interest, the subject is one that might well claim more detailed treatment than can, from exigencies of space, be given to it in these notes. Here it must suffice to state the problem in its simplest terms, without any attempt at determining the solution of it.

Ignoring for the moment the towns, and also certain special parts of the country, such as the Caucasus, the Cossack Territory, and Central Asia, Russia may be said to be inhabited by a peasantry—a peasantry which six-and-thirty years ago was in a state of absolute serfdom. The law of Feb. 19th, 1861, emancipated them from this condition, and subsequent laws[31] have provided a system which has given them large powers of local self-government combined with ultimate responsibility to the central authorities on the Neva. With the newly acquired freedom came newly acquired responsibilities and a corresponding need of increased education to meet those responsibilities. It would be idle to assert that education has advanced with the need of it, and few will be found to deny that the Russian peasantry is practically an uneducated peasantry. With absence of education are inevitably joined a degree of superstition and a ready credulity on all matters outside the individual's narrow circle of knowledge. In bare terms it would be harsh and unfair to describe the Russian peasantry as uneducated, superstitious, and credulous without mentioning their many good qualities. A deep religious faith, no lack of practical intelligence, and plenty of common sense in questions within his own immediate ken, added to a simple kindliness—an inexhaustible fund, indeed, of what may be comprehensively termed "human nature,"—these are some of the qualities which make the Russian peasant quite one of the most attractive and sympathetic of all peasants. It is the provision of this peasantry—who, be it remembered, are for the most part scattered over wide areas of country—with a system of medical aid which shall be at once effective, prompt, free of cost to the peasants, and not too ruinously expensive to the local authorities, which constitutes the problem these authorities are called upon to solve, for it is largely on the local governing bodies that this duty falls. The law only provides that every *uyezd* shall have at least one medical officer, but it is clear that in the great majority of instances this number would be totally, even absurdly, inadequate, and it is left to the *zemstvos* to make up the deficiency according to local needs. The greatest practical difficulty with which they are met is the scattered nature of the population with which they have to deal. There are, roughly, two main systems of providing medical aid, each of which has its advocates and its opponents. In one, the so-called "stationary"

[29] The preliminary report of the census carried out in January last has just been issued and states that the total population of the Russian empire was then 129,211,000.

[30] Ustav Vratchebmie, or Medical Statute; being the twelfth volume of the Svod Zakonov or Collection of Laws. The last edition was that of 1892.



[31] Notably those of Jan. 13th, 1864, which instituted the system of *Zemstvos*, and of July 12th, 1889, which introduced the local committees for peasant affairs.

Digitized by Google

(*statzionarnui*) system, the medical man lives either in the "district town" or in some village in his own division of the district; he there receives all patients who have need of him at certain fixed hours of the day, and only pays visits in case of necessity. In the other, the so-called *raziézdnui*[32] system, the medical men live in the central or "district" town, and, the district being parcelled out into divisions, they visit in turn every part of it on given days of the week or month. Under this system each village has its fixed day, perhaps twice in a month or oftener, when "the doctor" will be there to receive patients at a room in one of the cottages fitted for the purpose, or, if necessary, to visit them at their own homes. During the interval his patients are in the hands of a *feldscher*, whose functions will be defined later.

And now it will be asked, How do these systems succeed in practical working, and do they provide the peasantry with an adequate medical service? The answer must be "yes" and "no"—qualitatively, "yes"; quantitatively, "no." As far as quality is concerned the *uyezd* medical officer receives the highest university education; he is doubly a university graduate, for after obtaining the ordinary medical degree he proceeds to the further examination for the "Service" degree of *uyezdnui vratch*. Nor would it be possible to find a more conscientious, more devoted class of official. But so far as quantity is concerned it must be at once admitted that the supply of fully qualified medical aid to the Russian peasantry is inadequate. A few figures showing the number of medical men in the empire and their proportion to the population will suffice to prove this. According to an indisputable authority[33] on such matters the figures for 1890 were as follows. In a total population then reckoned at 110,000,000 (and the results of the recent census show that the total was considerably larger) there were 18 334 medical practitioners of all kinds, including those in the army and navy. There was, therefore, one doctor to every 6000 inhabitants. Further, when the towns were excluded and the rural population alone considered, it was found that the proportion of medical men was reduced to 1 in 9000; that in some districts it sank to 1 in 12,000; while in the whole government of Archangel there were but 14 doctors to 373,000 inhabitants. Slightly more recent figures which have since become available show practically no increase. From these figures, then, it is clear that at least in many parts of the country there is an insufficient supply of medical men. It will naturally be asked whether, in those parts of the country where there are no medical men or only an inadequate number, the peasants, all or some, are left without medical aid of any sort whatever. This, however, is not altogether the case, for there is in Russia, in addition to the class of fully qualified medical men, a second class of practitioners drawn from a lower social stratum and passing through a more restricted curriculum. As a matter of fact, *feldschers*, as these secondary practitioners are called, are more numerous than regular practitioners in Russia. So important, indeed, is the part they play and so thoroughly national is the whole system of *feldscherism* that they deserve a brief chapter to themselves.

IX.

The Feldscher.—Feldscherism Described and Discussed.

IT would appear to be a fact that Russia is the only country in Europe in which the principle of a secondary or subordinate class of medical practitioner is admitted. Some other countries may still in practice countenance the

Digitized by Google

existence of licence-granting bodies whose examinations require a minimum of medical knowledge to pass; but their diplomates belong practically to the same great social group as graduates with the highest university degree—the group of qualified medical practitioners. There is no secondary class bearing a different title, with a less thorough training and with inferior rights of practice. But in Russia there is such a class, and as the resulting system has been severely condemned by some critics and no less warmly defended by others, it has become a subject of frequently recurring controversy, and therefore merits some consideration here. There are two types of *feldscher*, the military and the civil. The latter will be chiefly considered here, but it is practically almost impossible to separate the two groups from each other, for a large number, even a majority, of civilian *feldschers* are, as a matter of fact, men who have once served in the same capacity in the army. Their very name, *feldscher* (which is, of course, the German word for army surgeon incorporated bodily into the Russian language), as well as their history, indicate clearly that the system was originally a military one, and their employment in civil life only a later development.

The origin of the system in the army is rather a curious one. It dates as far back as the early decades of last century and came about in the following way. It may be remembered that in a previous chapter, among the punishments mentioned as meted out to erring students in Peter I.'s Medical School in Moscow, the most severe was expulsion from the school to serve in the ranks of the army. A somewhat less drastic punishment, one reserved especially for students who persistently failed to pass their examinations, was to send them to serve, not in the ranks, but as bloodletters and barbers to the regiments. These were the earliest *feldschers* in Russia. This class of half-doctor, half-nurse, was found to be of real use in the army, and later a second supply of them was found. It seems that at that time the nursing of the patients in the hospitals was entirely done by the students—an arrangement which, of course, materially interfered with their medical studies proper. To obviate this the experiment was successfully tried of sending annually a certain number of boys, the sons of soldiers, to the hospitals to be trained in the arts of bloodletting, dressing of wounds, and nursing generally. In this way the students were set free from nursing duties, and a new class of army *feldschers* was formed. But these were still, it will be noted, entirely a military class, either nursing in the military hospitals or attached to regiments in the field. The civil *feldscher* is, in fact, only a recent growth of the present century, and dates from that great period of reform which followed the emancipation of the serfs in 1861, and the institution of the system of *zemstvos* a few years later. Even now the majority of *feldschers* in civil employ are drawn from the so-called "regimental (*rotnuié*) *feldschers*"—that is to say, men trained in the military hospitals or lazarets, as distinguished from the "school (*shkolnuie*) *feldschers*," or men trained in the army schools. These schools, of which there are four (in St. Petersburg, Moscow, Kief, and Tiflis), turn out a more thoroughly trained class of men than the so-called regimental *feldschers*, but the latter are far the more numerous. Of schools for educating civilian *feldschers* there are altogether twenty-one in Russia.

It will be interesting and essential to the right understanding of the *feldscher's* position to note briefly what is the course of training in these schools. To begin with, then, the school will generally be found attached to some large hospital in one of the central towns of a "government." The education begins early, pupils being taken generally at the age of thirteen years. As the boys are mostly drawn from the less educated classes of the population the first subjects they are taught are those of ordinary school education—scripture, history, arithmetic, Russian, Latin, writing, geometry, and geography. Later come the more advanced and the professional subjects proper. Of these an immense list is mentioned as included in the curriculum—botany, zoology, physics, anatomy, physiology, chemistry, pharmacology, pharmacy and pharmacognosy, pathology and therapeutics, surgery, diseases of children, eye diseases, ear and throat diseases, hygiene, epidemiology, venereal diseases, skin diseases—in a word, all the subjects required for a full medical degree. While the programme of a *feldscher* school includes all these subjects in full detail it is obvious that in the four years available only the elements of these sciences can be taught, or, at least, retained by the pupils. The last two years are spent in practical work in the wards. Here the work is mainly confined to the duties of nursing and of dressing the surgical patients; the physical examination of medical cases is also taught, and, it may be added, post-mortem examinations are attended and taken part in by the student. At the end of the four years the qualified *feldscher* leaves his school with a certain amount of medical knowledge and with certain more or less defined rights and privileges. These vary slightly with different schools, the diploma of each school bearing with it certain privileges which are stated in the *ustav*, or statute, of the particular school. Here, for instance, are the privileges—which are equally duties—of *feldschers* with the certificate of one of the central schools, that at Mogilef:—

"*Feldschers* of this school have the right to act independently in the following circumstances: (*a*) they may give the necessary aid in acute and dangerous cases in places where there are no medical men, but on the first opportunity it is their duty to inform the district medical officer (*uyezdnui vratch*) of the case; (*b*) they may act independently on the appearance of epidemic infectious diseases, such as cholera, scarlet fever, small-pox, measles, or typhus, but they should at once give information to the district medical officer and get instructions from him; (*c*) they may perform small operations, such as blood-letting, vaccination, the setting of fractures or dislocations, &c.; (*d*) they may act independently in cases of acute poisoning or threatened death from other causes; (*e*) they must act generally in accordance with instructions issued by the Medical Department. With permission of the district medical officer *feldschers* of this school may take charge of small *volost*[34] hospitals (in large, scattered districts), but they must present weekly returns of such hospitals to the district medical officer, and the control of the hospital is under the supervision of this officer."

The rights here mentioned may be taken as fairly typical of those conferred by all the Russian civilian *feldscher* schools, and they give a very fair picture of the sort of duties which a *feldscher* is expected to fulfil. As will be seen from the second paragraph, he may be in sole charge of small hospitals, and not only is this often the case, but he is also not infrequently in almost sole medical charge of the population of a large district. Not, of course, immediately after leaving his school, for it is clear that a youth leaving the *feldscher* school at the age of seventeen years, after a four years' course, part of which was devoted to ordinary school subjects and only two years to practical work in the wards, could not be regarded as qualified to take the sole charge of patients. Possessed of that little knowledge which in medicine, more perhaps than in anything else in life, is a dangerous thing, some further training is essential if the *feldscher* is not to be more active for harm than for good. The next step in his career, therefore, as a rule, is for him to become attached to some hospital, when he occupies a really useful position, somewhere between the positions of a male nurse and a house surgeon. Here the *feldscher* may spend the rest of his life, or he may in time become appointed by a district *zemstvo* as the sole permanent medical adviser to the peasant population in some country district. In most parts of European Russia he will have the advantage of the advice and control of the district medical officer. Nominally, indeed, the health of the whole population of the district is in the hands of the medical officer, whose orders the *feldscher* carries out during the intervals of his superior's fortnightly visits. But practically in a large number of instances the terms above used are nearer the truth, the *feldscher*, living on the spot, being the real permanent medical adviser, the district medical officer, who visits the village at stated intervals, having only a consultatory and controlling influence.

The whole question of the system of *feldscherism* has been, and still is, hotly discussed in Russia. There are those who affirm that the system is the very foundation-stone of the whole structure of *Zemskaia Meditzina* (or medical aid to the peasants at the cost of the *zemstvos*), and that were it done away with the peasants who have a voice in the *zemstvo* would not vote another *kopeck* towards maintaining the structure. According to those who hold this view, the peasants regard the *feldscher* as an institution peculiar to

[34] A "volost," as has been explained, is a collection of village communes for administrative purposes.

Digitized by Google

themselves and one not lightly to be done away with. "The doctor," they will say, "oh! he is the gentleman's doctor, but the *feldscher* is the *moujik's* doctor." On the other hand, there are equally acute observers who hold quite a contrary opinion. The peasants, according to this school of observers, are only content with a *feldscher* when they have never had the opportunity of being treated by a doctor. Provide them, they say, with properly qualified medical aid and they will at once take the fullest advantage of it; they even now mistrust the *feldscher*, and much more willingly submit to the advice of the medical officer. *Feldscherism*, according to this view, far from being the keystone of a successful system of medical aid, is the greatest stumbling block to its development in the right direction.

It is, perhaps, rash for a foreigner to attempt to decide on the value of any national institution or custom, and the one under consideration is a thoroughly national institution—a system found in no country outside the frontiers of Russia. This is, indeed, in the eyes of those who uphold the system, one of the strongest arguments in its favour. They are proud of the fact and assert that in this way Russia has solved a problem with which all nations are faced, but of which no other nation has found a satisfactory solution. They declare that even in those countries, such as England, with the largest number of medical men in proportion to the population, there will still not be enough, and many of the people will remain without medical aid or seek that of druggists and unqualified practitioners. In Russia druggists are strictly forbidden to give medical advice; unqualified practice and charlatanry are common enough, "wise men" and "wise women" existing in every village; but it is as a counterbalance to these, it is as a means of preventing the peasant falling into such hands, that the system of *feldscherism* is so highly lauded by those who approve of it. The argument is ingenious and may be readily accepted as far as it goes; but it is not the whole truth. The fact would appear to be that *feldscherism* is at best a compromise—an attempt to solve a difficult problem by half-measures. As a satisfactory permanent solution of the problem it can scarcely be accepted. Medical aid to a population, whether of peasants or any other class of people, if it is to be supplied at all, should surely be of the highest quality possible. In dealing with health and disease, life and death, half-measures have a way of being either useless or worse than useless. What, however, can be truly said in defence of *feldscherism* is that even half-trained medical aid is better than none at all; that as there is an insufficient supply of qualified medical men the peasants would, in the absence of *feldschers*, be entirely at the mercy of the "wise men" or "wise women" of the villages. It may be freely admitted that such a lot would be infinitely, incomparably, the worse of the two. The *feldscher*, if he be an intelligent man—and they are, as a rule, a most intelligent, kindly, willing race of men—gains a great deal of practical knowledge in his hospital and other experience, and this in a large number of simple cases will prove of real value; while the "wise" man or woman (some apology is due to the *feldschers* for mentioning them in the same sentence, and thus even appearing to compare them) is for the most part guided by traditions and superstitions which often lead to the most disastrous and hideous results in practice.[35] As an important and earnest effort on the part of the authorities to provide the peasantry for the time being with properly trained medical assistance and as an alternative to the mischievous help of "irregular practitioners" the present system may be honestly commended. The *feldscher* is, of course, much cheaper than the doctor, even if there were sufficient doctors available, and this has been shown not to be the case. And regarded as a highly trained male nurse, always working under a medical man, the *feldscher* is beyond question an admirable institution of the greatest use in hospitals and even in villages. But where the present system seems to be less commendable, at least in the eyes of a foreigner, is in the development it has taken in the country districts, where the peasants are often left for long intervals in the *feldscher's* sole medical charge. This, if it is to be commended, can only be regarded as a temporary measure, corresponding to the transitional economical and intellectual state of the peasantry at the present time. The principle of a secondary class of medical practitioner, with inferior education, training, and rights of practice, appears wrong. It seems probable that its existence is only a question of time, though it must of course be a very long time, for the number of qualified medical practitioners in Russia to reach a point when they shall be accessible to all. There will then be no need of a secondary class of practitioner; the *feldscher*, as such, will disappear, or will remain as an exceptionally well-trained male nurse.

Feldscherism is not likely soon to be done away with; indeed, it is obvious from what has already been said that until the number of medical men can be proportionally increased, to do away with it would be an unmixed misfortune for the peasants. There are at present more *feldschers* than medical men in Russia. The numbers in 1892 (the latest available) were 12,174 (civil) medical men and 16,568 (civil) *feldschers*. In the same year, in the twenty-one civil schools 204 *feldschers* finished their course; but, as already stated, the majority of *feldschers* in the country are trained either in the military hospitals or in the army *feldscher* schools.

A very intelligent man, a Russian army *feldscher*, put into black and white his views on the whole subject of *feldscherism*. His little essay contained much really useful information, some of which has been made use of above, and it ended thus: "Russian doctors not only do not approve of *feldschers*, but they contend with *feldscherism* as with the phylloxera or any other destructive insect. But they cannot possibly do without *feldschers*. There are comparatively few doctors in Russia (say 15,000), and if they were to work unassisted for twenty-four hours in the day, still two-thirds of the population would be left without medical aid."

X.

Russian Universities and Medical Education in Russia.—The Ten Universities.—The Ministry of Education.—The University Authorities.—The Faculties.—The Medical Chairs and Professors.—The Curriculum.—The Degrees, and Mode of Obtaining Them.—State Examinations.—Statistics of the Universities.—The Army Medical Academy in St. Petersburg and Sir James Wylie.

IN Russia a medical practitioner must not only possess a diploma, but he must have obtained his medical education and his diploma from a university; in other words, all Russian medical practitioners are university graduates. Licence-granting colleges or schools of medicine or surgery are institutions unknown in Russia; and so also, *à fortiori*, are schools or colleges affording facilities for medical training, though not themselves granting diplomas to practise. It is at the universities alone that students can obtain both training and diploma. There is one apparent exception to this rule, and that is the Imperial Academy of Military Medicine in St. Petersburg, or, as it is more generally called, the Army Medical Academy. Its exceptional nature is, however, more apparent than real, for the Academy may be regarded for all practical purposes as a substitute for the absent faculty of medicine in the University of St. Petersburg, which (since the very recent addition of a medical faculty to that of Odessa) is now the only Russian university without such a faculty. There are, in all, ten Russian universities, including those of Helsingfors and Dorpat (now Yurief), which have only become Russian since their foundation. They may be briefly enumerated, together with their dates of institution and mode of origin. The University of St. Petersburg was opened in 1819 in the reign of Alexander I. It was practically a development, with new organisation and powers, of the former so-called "Principal Pedagogic Institute." The University of Moscow was instituted by the Empress Elizabeth in the year 1755. It is consequently the oldest purely Russian university. The first medical degree granted in Russia was conferred by this

[35] Quite recently a "wise woman" (*znakharka*) advised a mother to put gunpowder into her baby's eyes and apply a match as a cure for ophthalmia. The mother did it; the ophthalmia was destroyed, but so were both eyes, and the baby died in agony. Another woman roasted her baby in the stove under similar advice. But the horrors of this sort of "practice" are too great to dwell upon. Nor must it be supposed that they are confined to Russia; they would appear to occasionally occur in all countries.

Digitized by Google

University in 1794. The University of Kazan was founded by Alexander I. in 1804. The University of Kharkof was opened a year later by the same Emperor. The University of Novo-Rossiisk (i.e., New Russia), in Odessa, was instituted by the late Emperor Alexander III. in the year 1865 by the conversion into a university of the pre-existing Richelieu Lyceum. This was an important institution which had been founded by the Duc de Richelieu, a French *émigré*, who in 1830 became the first Governor of Odessa. The University of St. Vladimir, in Kief, was instituted in 1833 and opened in the following year by the Emperor Nicholas I. It took the place of the former Polish University of Vilna, which was suppressed after the Polish rising of 1833. The University of Warsaw dates from 1869, when the so-called *Glavnaia Szkola*, or Head School, was converted into a university. It has a statute of its own dating from the year of its foundation, and differing from the statute common to most of the other Russian universities. The University of Yurief was known as the University of Dorpat prior to the year 1892. It has been under a Russian statute since the year 1802 The older university was founded by the great Swedish ruler, Gustavus Adolphus, in 1632 The University of Tomsk, the sole one in Siberia, was brought into existence in 1887. It has at present only a medical faculty, but it is expected that very shortly a juridical faculty will be added. The Alexander University of Helsingfors is the successor of the old Finnish University of Abo. This was removed to Helsingfors after the destruction of Abo by fire in 1827. The older university was founded in 1640.

With the exception of the last four in the above list all Russian universities are under one common code of laws or statute, the so-called University Statute (*Universitetski Ustav*). There have been four such statutes in successive operation during the present century, those of 1804, 1835, 1863, and 1884. It is the last, that of 1884, which is now in force. Under the older statute of 1863 the universities enjoyed wider rights of self-government, and were in general more independent of the State authorities, than is the case under the present law. The relation which the universities now bear to the Government authorities may be very briefly stated before passing on to consider the medical faculties and the course of education provided by them. The universities, as educational institutions, are administratively under the Minister of State for Public Instruction (*Ministr Narodnago Prosviéshtohénia*). For the purposes of this Ministry the country is divided into fifteen districts[36] or circuits (*okrugs*), each of which is administered by a curator (*popetchitel*) or representative of the Government. This official is in direct touch with the university as well as with all other educational institutions of any kind whatever that may exist in his district. He has considerable powers, among which may be mentioned the appointment of the deans of faculties and of some other university officials; and he is, moreover, the direct and only link between the Government and the universities, all communications between the two having to pass through his hands. The internal affairs of the university are managed by the following authorities: (*a*) the rector, the practical working head of the institution; (*b*) the university council—i.e., all the professors, under the presidency of the rector; (*c*) the university board—i.e., all the deans of faculties and the inspector of students, under the presidency of the rector; and (*d*) the inspector of students, whose functions are generally those of a proctor.

A complete Russian university should contain four faculties—namely, a Historico-Philological, a Physico-Mathematical, a Juridical and a Medical Faculty. It will be observed that there is no mention of a Theological Faculty, and, as a matter of fact, the University of Yurief (Dorpat) is unique among Russian universities in possessing such a faculty. A fully equipped medical faculty contains the following twenty-three chairs:—(1) Anatomy; (2) Physiology; (3) Histology and Embryology; (4) Medical Chemistry; (5) Pharmacognosy and Pharmacy; (6) Pharmacology, with prescription-writing, toxicology, and instruction in the use of mineral waters; (7) General Pathology; (8) Pathological Anatomy; (9) Medical Diagnosis; (10) Special Pathology and Therapeutics; (11) Nervous and Mental Diseases; (12) Dermatology and Syphilology; (13) Therapeutic Faculty Clinique; (14) Therapeutic Hospital Clinique[37]; (15) Operative Surgery with Topographical Anatomy; (16) Surgical Pathology with Desmurgy[38] and instruction upon Dislocations and Fractures; (17) Surgical Faculty Clinique; (18) Surgical Hospital Clinique; (19) Ophthalmology, with Clinique; (20) Midwifery, Gynæcology, and Diseases of Children, with Cliniques; (21) Medical Jurisprudence; (22) Hygiene, with Epidemiology, Medical Police, Medical Statistics, Epizoology, and Veterinary Police; and (23) History and Encyclopædia of Medicine.

There are two kinds of professors in a Russian university, the ordinary and the extraordinary (*ordinarnui* and *extra-ordinarnui*). The distinction between them may be made clear by stating that the ordinary professor takes a higher rank than the extraordinary, being entitled to a position in the fifth class, or *tchin*, in the system of ranks already briefly explained in Section VII.; while the extraordinary only ranks in the sixth class. The former also receives a higher stipend than the latter, the sums being respectively 3000 roubles and 2000 roubles[39] per annum. In the University of Tomsk, in Siberia, these stipends are increased by one-half in consequence of the isolation and other disadvantages of an appointment in that distant city. There is another class of professors to who allusion must be made; these are the so-called supernumerary (*sverkhshtatnui*) professors—i.e., those who are not on the *shtat* or list of professors proper. They may be either ordinary or extraordinary, and are either teachers raised to the rank of professor before a vacant chair offers itself for occupation, or professors who, having served for thirty years, are placed on the retired list, although they continue to deliver lectures. In addition to the professors there are an indefinite number of *privat docents* in a Russian university. The system, as well as the name, has been borrowed from Germany.

The number of students is not limited. Moreover, it is worth noticing that the number of medical students never has been limited. Even in the stormy period of 1848, when the revolutionary wave which swept over Europe was repeated in the serious student disorders in some of the Russian universities, and when the Emperor Nicholas I. limited the number of students to be admitted to each university to the comparatively low figure of 300, the medical faculties were expressly exempted from any such limitation. For admission to the universities now a student has to present a certificate of proficiency from one of the Government *gymnasia*, or high schools, or from some other school recognised as equivalent by the Minister of Education. Students are allowed to enter only at one period of the year, on or before Aug. 20th (old style), that being the day on which the autumn session or half-year begins. There are two sessions in the year, from Aug. 20th to Dec. 20th, and from Jan. 15th to May 30th. The vacations are consequently of rather less than a month's duration at Christmas, and of nearly three months' duration in the summer. The entering student or freshman must be at once inscribed in one or other of the four faculties. The fees are not large; each student pays a sum of 5 roubles (about half a guinea) each half-year, and an additional sum of 1 rouble for each weekly lecture he arranges to attend—that is to say, that if, for example, he arranges to attend eighteen, twenty-four, or thirty lectures in the week, he will pay 18, 24, or 30 roubles for that half-year.

The full list of medical degrees obtainable at a Russian university is a long one, including, as it does, not only the two ordinary medical degrees, a lower and a higher, found in almost all universities in other countries, but certain other degrees in addition connected with the public services, and

[36] The fifteen districts are those of St. Petersburg, Moscow, Kazan, Orenburg, Kharkof, Odessa, Kief, Vilna, Warsaw, Riga, the Caucasus, Turkestan, Eastern Siberia, Western Siberia, and the Amur.

[37] The distinction between a "Faculty Clinique" and a "Hospital Clinique," whether Therapeutic (i.e., Medical) or Surgical, is briefly as follows. The first is endowed and supported by the university, and the second usually belongs to the town or city authorities and is only subsidised by the university. The Faculty Clinique is attended by students in their fourth year; in it everything is carried out, as far as possible, in an ideally scientific manner—there is no haste, and students can study selected cases at their leisure. The Hospital Clinique, on the other hand, is attended by fifth-year students, and it is conducted on the lines of an ordinary hospital; the cases are not selected, and men are enabled to learn here the practical working of a large hospital, and to get accustomed to the rapidity of diagnosis and judgment necessary in a large general practice

[38] The word "Desmurgia" includes what may be summed up as practical minor surgery and bandaging.

[39] A rouble is a little over two shillings. These stipends are equivalent, therefore, to rather more than £300 and rather more than £200 respectively.

Digitized by Google

qualifying those who obtain them to hold some of the appointments described in an earlier chapter. The degrees are consequently divided into three groups, called respectively the learned-practical (*utcheno praktitcheski*), learned-official (*utcheno-slushebnui*), and special-practical (*spetzialno-praktitcheski*) groups of degrees. In the first group, the learned-practical, there are three degrees—namely, in ascending order of value, those of (*a*) *lékar*, or practitioner; (*b*) doctor of medicine; and (*c*) doctor of medicine and surgery. In the second group, the learned-official, there are also three degrees, those of (*a*) district medical officer (*uyezdnui vratch*, whose functions were defined in an earlier chapter); (*b*) medical member (accoucheur or operator) of a *zemstvo* medical board; and (*c*) medical inspector to a *zemstvo* medical board (*inspektor vratchebnoi upravui*). In the third group, the special-practical, are the degrees of (*a*) dental surgeon (*zubnoi vratch*); (*b*) dentist (*dantist*); and (*c*) midwife (*povivalnaia bubka*). It may here be added that all chemists and druggists, and all veterinary surgeons, are compelled to obtain a diploma by examination conducted in a university before being allowed to practise their calling. Of these many degrees much might be written, but it will suffice here to summarise the requirements of the universities for the two most important degrees, those of *lékar* and Doctor of Medicine, only adding a few condensed notes on the method of conferring the other degrees.

The degree or title of *lékar* is the lowest degree entitling the holder to practise. The curriculum required for it extends over five years, or ten sessions, during which the student must attend lectures in all the subjects in which he is going to be examined at the end of that period. There are class-examinations each session, and, in addition, at the end of his fifth session the student has to pass the so-called "half-course" (*polu-kursovui*) examination before he can continue his curriculum. At the end of the five years the student presents himself for examination for the degree of *lékar*. He must hand in the following certificates:—(*a*) of attendance at the university for ten sessions; (*b*) of good behaviour from the university inspector of students; (*c*) of having passed his half-course examination, with any remarks of the examiners; and (*d*) detailed certificates from each professor as to the work done by the candidate since the "half-course" examination, countersigned by the dean or secretary of the medical faculty. In addition, the candidate must send in his photograph and the sum of twenty roubles (about two guineas), the examination fee. It will be noticed that in this way the examiners are enabled to gain a very good idea of what sort of work the candidate has done as a student, and this may have some influence on the result of the examination.

The examination is conducted by a Government examining committee or board (*ispuitatelnaia commissia*) annually appointed by the Minister of Education. The board consists of five members and a president. The subjects of examination are divided into five groups, corresponding to the five members of the board, each of whom appoints the examiners in his particular group. The examiners so appointed may be selected from the professors and *privat-docents* of the same university in which the examination is to take place, or from eminent men, specialists in the particular subject, from elsewhere. In the latter case the choice must be confirmed by the Minister of Education. The following are the five groups and the division of subjects between them:—

First Group: (*a*) Descriptive Anatomy; (*b*) Histology; (*c*) Pathological Anatomy and Pathological Histology; and (*d*) Operative Surgery and Topographical Anatomy.

Second Group: (*a*) Physiology; (*b*) General Pathology; (*c*) Medical Chemistry; (*d*) Pharmacology, Prescription Writing, and Mineral Waters; and (*e*) Pharmacy and Pharmacognosy.

Third Group: (*a*) Special Pathology and Therapeutics; (*b*) Nervous and Mental Diseases; (*c*) Diseases of the Skin and Syphilis; (*d*) Diseases of Children; (*e*) Clinical Examination in the Medical Wards; and (*f*) Clinical Examination in the Skin and Syphilitic or in the Children's Wards.

Fourth Group: (*a*) Surgical Pathology, with Desmurgy and Treatment of Dislocations and Fractures; (*b*) Ophthalmology; (*c*) Midwifery and Gynæcology; (*d*) Clinical Surgery; and (*e*) Clinical Ophthalmology and Midwifery.

Fifth Group: (*a*) Hygiene and Medical Police; (*b*) Legal Medicine and Toxicology; and (*c*) Epizoology and Veterinary Police.

The examination in all these subjects is entirely of a *vivâ-voce* or practical character. There are no written examinations in any subject as with us in England. The principal question asked the candidate is drawn by the candidate himself from a ballotting-urn, in which are placed a number of slips of paper with questions written on them. The first question drawn may be refused, but there is only a second chance, and the second question drawn must be answered by a candidate who has declined the first. In addition to the principal question the examiners have the right to ask any other reasonable question within the limits of the particular subject. The examiners classify the result in each case as either "unsatisfactory," "satisfactory," or "very satisfactory." Two "unsatisfactories" are sufficient to stop any further examination and "plough" the candidate. For honours, or, as it is called, *lékar s' otlitchiem* (or *cum eximiâ laude*), it is necessary to obtain at least eleven "very satisfactories" out of the twenty-three subjects, and not one "unsatisfactory." Should the candidate fail he may come up again after two sessions, and should he fail a second time he may try a third time; but this is his last chance, as under no circumstances may he be examined a fourth time. There is no minimum age-limit mentioned in connexion with the degree of *lékar*. Practically, however, as most boys leave the *gymnasia* about the age of eighteen, and as the curriculum extends over five years, this degree is usually taken at the age of twenty-three.

Having obtained the degree of *lékar* the graduate may at once proceed, if he wishes, to obtain the higher degree of Doctor of Medicine. This degree is still one of the "learned-practical" degrees; but should the new regulations, which have for some time been under the consideration of the authorities, come into force, it will be raised a step higher and become a purely "learned" (*utchenui*) degree. To obtain it under the present regulations it is necessary to have the lower qualification of *lékar*, to pass a written examination, and to present and defend a dissertation. The written examination consists of a paper containing two questions only. When this is satisfactorily passed the candidate may submit his dissertation to the approval of the faculty, and when that is gained he must print not less than 500 copies and lodge them with the university authorities. This is done at the candidate's own expense, and should the dissertation be of any length the expense is sometimes considerable. There is even some talk of increasing the number of copies required, at least in the Army Medical Academy in St. Petersburg (where 500 complete copies and 300 abstracts of the dissertation are now demanded), as the list of foreign and Russian universities and medical institutions to which copies of each dissertation are sent is an ever-increasing one. Appended to the dissertation must be a certain number of definite propositions or conclusions (*theses*), of which six at least must be purely medical in character. The public defence of the theses takes place at a meeting which is duly advertised, and which is freely open to the general public. Not only members of the university, but anyone present, may rise and controvert the statements or views of the candidate. As a rule, however, the three official "objectors" (*vozrashatelui*) appointed by the faculty are the sole speakers on these occasions. The result is announced immediately, and if the verdict is satisfactory the "faculty oath" is read and signed, and the candidate, now a candidate no longer, is an accepted Doctor of Medicine. In the rare case of rejection of a dissertation the candidate may come up again after an interval of not less than three or more than six months to defend either the same dissertation a second time or a newly written one.

Should the proposed new regulations for obtaining the doctorate become law considerable changes will be introduced into the method just described. Three years will have to elapse from the time the candidate has obtained the degree of *lékar* before he will be permitted to present himself for the higher one. He will then have to pass a fresh searching examination in all the subjects required for the lower degree, and this examination will be specially directed towards some one special branch of medical science chosen by the candidate. There are seventeen such branches of specialism named, but it is scarcely necessary to repeat them here.[40] The most important point is that practically under

[40] Vide THE LANCET, Oct. 26th, 1895.

Digitized by Google

these regulations the M.D. degree would in future be obtainable by specialists only. The dissertation would be required as now, but it would have to be presented within five years of passing the examination; failing this the examination would have to be repeated. It is still uncertain whether the new regulations as thus drafted will be ratified by the Medical Council.

The degree of Doctor of Medicine and Surgery is, as a matter of fact, very rarely taken. It is obtained in the same way as that of Doctor of Medicine, but the examination in surgery, theoretical and practical, is especially searching.

The conditions for obtaining the "learned-official" (*utcheno-sluzhebnui*) degrees are adapted in each case to the special kind of knowledge which the holder of the degree will be likely to require in the particular office which the degree will entitle him to fill. Thus, for example, a candidate for the title of "district medical officer" (*uyezdnui vratch, vide* Chapter VIII.) must have one of the ordinary medical degrees already described, and must pass a special examination in legal medicine, medical police, first aid, epizoology, and in the duties and social relations of a district medical officer. A candidate for the degree of "operator" or "accoucheur" to a *zemstvo* medical board must have the degree of *uyezdnui vratch*, and must pass an examination in surgery or midwifery, as the case may be. An inspector of a medical board (*inspektor vratchebnoi upravui*) must have the degree of M.D., and have been in the public service for at least six years, and he must pass a very wide examination, not only in the special subjects just named as needed for the title of district medical officer, but also in medical law, State medicine, and medical administration, veterinary police, and pharmacognoscy.

Of the "special-practical" (*spetzialno-praktitcheski*) degrees little need be said here. A "dentist" (*dantist*) and a "dental surgeon" (*zubnoi vratch*) must pass a university examination before being permitted to practise. It may also interest many readers, particularly those who approve of a proposed Bill which has been the subject of much recent agitation in the medical world in England, to know that in Russia a midwife (*povivalnaia babka*) must be properly trained and pass an examination before she can follow her calling, and that this examination is conducted in the universities.

Before closing this account of the medical degrees conferred by Russian universities it is necessary to add that in Russia all druggists are by law compelled to pass an examination as to their fitness for such an occupation. There are three titles, those of "apothecary's assistant," "provisor," and "master of pharmacy" or "*aptekar*." An "apothecary's assistant" must have been a pupil for not less than three, or more than five, years in a recognised druggist's shop, not in a village, and must pass an examination. A "provisor" must have had the lower title for three years, must have attended courses of lectures on mineralogy, botany, zoology, chemistry, physics and pharmacology, &c, and must pass a written examination in these subjects. A "master of pharmacy" must first have obtained the title of provisor, and must pass a still wider examination in the subjects just named, and he must also present and defend a dissertation with at least six *theses*. The examination is largely practical, and includes chemical and medico-legal analyses. For veterinary surgeons there are also three titles of ascending value, those of "veterinary assistant," "veterinarian" (*veterinar*), and "master of veterinary science."

The following Tables contain interesting statistics of the medical faculties and degrees of the Russian universities (excluding Helsingfors). The figures are for the year 1895. They have been most kindly furnished by the Ministry of Public Instruction. The medical faculties of the universities have alone been referred to, to the almost complete exclusion of another great degree-granting body, the Army Medical Academy [41] in St. Petersburg. The Imperial Academy of Military Medicine, to give it its full title, is intended mainly for the training of surgeons for the services. It is not, however, confined to this, and many civilian practitioners have gained their diploma or degree at the Academy. The curriculum here is practically the same as at the universities, and so are the degrees and the mode of obtaining them. The large majority, however, of the students ultimately enter the army or navy medical services.

The Academy is older than any of the universities, with the exception of that of Moscow. It was founded by the Emperor Paul in the year 1798, and opened in 1800. Next year the centenary of its foundation is to be commemorated with all due solemnity in St. Petersburg, and in honour of the occasion a detailed history of the institution will be published, and is, indeed, already in course of preparation. Space will not permit here of more than a brief mention of some points in its history. The Academy has been successively under the Ministry of the Interior, under

* It is necessary to note in connexion with this table that under the system of examination for degrees by Government commissions it is scarcely correct to say that such and such a university conferred so many degrees in any given year. Students may pass their examination in any university they choose, no matter where they have completed their curriculum. The above figures refer to students who obtained their degrees in the examinations conducted at the universities named. That they were not all students of the university where they passed their examination is shown by the following example: In Moscow (*vide* the report of the University for 1895) 174 Moscow students obtained the title of *iékar* in the year 1895; but the total number of students who obtained the title in that year by examination in the Moscow University was 217. Confusion may easily arise between the two sets of figures.

† Only seven universities appear in this table, as there is no medical faculty in the University of St. Petersburg, nor was there one in that of Novo-Rossiisk, in Odessa, until last autumn. In 1896 the Army Medical Academy in St. Petersburg granted the title of *iékar* to 136 successful candidates.

[41] Voenno-Meditzinskaia Akademia; in rendering this "Army Medical Academy" it should be mentioned that the Russian words imply that both the military and naval services are included in the objects of the Academy.

Digitized by Google

that of Public Instruction, and finally, since 1839, under the Ministry of War. For many years, early in the century, its fortunes were closely linked with those of a distinguished Scotchman, Sir James Wylie, who for a quarter of a century occupied the honourable position of head of the Army Medical Department in Russia, and was practically the head of the whole profession in the country for that period. Wylie first went to Russia in the year 1790, when, after an examination, he was appointed surgeon to the Eletzk Regiment. In 1798 he was appointed body surgeon to the Emperor Paul. The story of his having attracted the attention of the Czar by his successful treatment of a certain Count Kutaisof by lancing a large abscess in the neck after other surgeons had despaired of success—a story which gave rise to the saying that "Wylie had made his fortune by cutting a count's throat"—may be taken for what it is worth. It is certain that he gained the confidence of both Paul and his successor, Alexander I., who promoted at a charge of from 45 to 60 roubles per month. The medal, of which an illustration appears here, was struck on the occasion of Sir James Wylie completing his fiftieth year in the Russian service in the year 1840. For the loan of the medal and permission to reproduce it thanks must be given to a collateral descendant of the baronet now resident in St. Petersburg.

Since the death of Sir James Wylie the Army Medical Academy has always had for its president one of the most distinguished army surgeons of the day. The names of Pelican (1846–57) and Yenokhin (1857–62), to mention but two, are still remembered with honour. At present the Academy is under the presidency of Dr. Victor Pashutin, who is also President of the Medical Council, and as such occupies the most honourable position in the medical profession in Russia. It may be added that the present head of the Army Medical Department, which is now called the Army Medical Board (*Upravlenić*), over which Wylie

FIG. 11.

Medal presented to Sir James Wylie, Bart., Physician to the Emperor Alexander I., first Director of the Academy of Military Medicine, and Founder of the Wylie Clinical Hospital in St. Petersburg.

him to the highest honours in his power to give. In brief, Wylie in his time was the most prominent figure in the medical world in Russia. It was more particularly in the direction of improving the medical services of the army and navy that his professional activity found scope. The Napoleonic wars had given a stimulus to all departments of the army, and in 1811 the first Medical Department of the War Ministry came into existence. Wylie was its first director, and this post he retained until the year 1836. He took a prominent part in the campaigns of 1812 and 1813, and it was in recognition of this that, at the personal request of the Emperor Alexander, he obtained his knighthood, and later his baronetcy. He was knighted by the Prince Regent, who used the famous Cossack Platof's sword for the occasion, on board one of the Russian ships then lying off Portsmouth. In Russia his memory is perpetuated by the fact that attached to the Army Medical Academy, of which he was for many years the president, is a clinical hospital built from funds which he left for that purpose, and named after him. Its full name is the Michael Clinical Hospital of Baronet Wylie (pronounced in Russian *Vilié*), but it is more commonly known as the Wylie Clinique. It is not the principal clinical hospital of the Academy, but occupies three sides of a square, in the centre of which is a life-size statue of the founder on a high pedestal.[42] The cost of erecting the hospital was 943,000 roubles (nearly £100,000); it was opened in 1873. It contains 150 beds, made up as follows: 40 medical, 40 surgical, 20 ophthalmic, 30 obstetric and gynæcological, and 20 for children's diseases; 120 of the beds are free, the remainder are occupied by paying patients,

[42] The following is a more detailed description of the statue. The pedestal is of grey marble, the figure is seated, and holds in one hand the reformed statutes of the Academy; caryatides adorn the angles of the pedestal, and between them are bas-reliefs representing incidents in the life of Wylie. His coat of arms and that of the Academy also appear.

presided for so long, is Dr. Alexander Remmert, the corresponding position in the navy being occupied by Dr. Vladimir Kudrin.

XI.

The University Cliniques in Moscow.—Their Origin.—State and Private Generosity.—The Cliniques Described.—The Systems of Heating, Ventilation, Water-supply, &c.—The "Institutes."—The Operating Theatres.—The Hospital System in Russia.—Hospitals in Town and Country.—The "Hospital Statute."—The Medical Staff of Hospitals.

PRIVATE munificence and State and municipal liberality have combined to produce in Moscow one of the largest and best-equipped series of cliniques attached to a university to be found in Europe. Until some ten years ago the clinical work of the Moscow students was carried on in two large hospitals, the old and new Catherine (*Staraia-* and *Novaia-Ekaterininskaia*) Hospitals, in the centre of the town and not very far from the University buildings. But as far back as 1873 the need of wider accommodation for patients and of more modern clinical facilities for the professors and students had made itself felt, and in that year an elaborate scheme for a new clinique was proposed by one of the professors and submitted to the University authorities. It was warmly approved of by the medical faculty, but was for some reason rejected by the University Council, and consequently the scheme for a time came to nothing. But only for a time; nine years later it was revived at a more auspicious moment in consequence of the generous offers of two wealthy ladies, Mesdames Pashkalof

Digitized by Google

and Morozof, who announced their readiness to provide funds for building two special cliniques, one of forty beds for obstetric cases and one of sixty beds for the treatment of nervous diseases. This was really the first step towards the realisation of the wishes of the medical faculty for new clinical buildings. In 1883 the University obtained authority to sell the ground and buildings of the old clinique, and to employ the sum thus realised towards the erecting of a new one. A commission was formed to carry out the scheme, and this commission was presided over by Professor Sklifosovski, the president of the organising committee of the International Congress about to be held in Moscow.

In the autumn of 1884 the municipality of Moscow most generously ceded to the University a large space of vacant ground on the *Diévitché Polé* (or "Field of the Virgin") as the most suitable site for the new clinique. The ground thus ceded was very nearly forty-five acres in area, and at about the same time this was increased by another most opportune gift of adjoining land. The second gift of land was due to the generosity of Madame Morozof, one of the ladies already mentioned, who had offered to build at her own expense a hospital of sixty beds for the treatment of nervous diseases, and who now presented the University with over fourteen acres of land upon which to build it. The Commission was thus relieved of one great difficulty and expense, that of finding an appropriate site for the new buildings. Matters now moved forward rapidly. A small committee of three, consisting of M. Bikovski, the architect of the University, and Professors Sréziref and Erismann, was sent abroad to study some of the principal foreign university cliniques. They visited Munich, Zürich, Berne, Strasburg, Heidelberg, Leipzig, Halle, Berlin, and Paris, and on their return a detailed scheme of the new buildings was drawn up. It was found that to carry this out completely a further sum of two and a half million roubles—that is to say, over £250,000—would be required; while even if only the most essential parts of the scheme were executed a sum of at least 1,711,000 roubles would have to be asked for. Ultimately, in the spring of 1886, the Government gave a grant from the treasury of 2,150,000 roubles, or about £220,000, for the purpose of building the new clinique. But the generosity of the State and of private individuals was not yet exhausted. In 1887 the Government voted an annual sum of 30,000 roubles for the endowment of the Psychiatric Clinique; in 1889 it granted two annual sums of 15,750 and 16,880 roubles respectively, for the Obstetric and Gynæcological Cliniques; and finally in 1890 the Council of State consented to grant in full the demands of the University for the furnishing and equipment of all the other cliniques and laboratories, and, with very slight reductions, to endow them with the sums asked by the University authorities. The most striking examples of private munificence, in addition to those already mentioned, have been the gift from M. Solodovnikof of funds to build the Clinique of Dermatology and Syphilis, the erection by Madame Bazanof of the Clinique for Diseases of the Ear, Throat, and Nose (at a cost of 515,000 roubles), and the donation of 70,000 roubles from Madame Barbe-Alexéief for the construction of the general out-patient department. Many of the cliniques bear the names of their generous founders.

It has been necessary to enter into some detail with regard to dates and figures, at the risk of appearing tedious, in order to give the reader some idea of the scale upon which the scheme of providing the first of Russian universities with adequate clinical accommodation has been conceived and carried out. From first to last, not far short of half a million sterling must have been expended upon it, while the annual grant from the State Treasury is considerably over 415,000 roubles (about £43,000). The buildings, which were erected from the designs of M. Bikovski, the architect of the University, and MM. Goedicke and Strom, of St. Petersburg, cover a space of ground measuring 3920 feet from N.E. to S.W. and 525 feet from N.W. to S.E. The "Field of the Virgin" upon which they stand is a large irregular open space, taking its name in all probability from the New Convent of the Virgin (*Novo-Diévitchi Monastyr*) close by. This striking and picturesque mass of ecclesiastic buildings, surrounded by high walls like some mediæval fortress and surmounted by a characteristic dome-capped tower, is one of the most interesting of the innumerable monasteries and convents in and around Moscow. It was founded in 1524 to commemorate the capture of Smolensk by the Russians from the Poles. The buildings of the clinique are about twenty minutes' drive from the Kremlin, which for practical purposes may be regarded as the centre of Moscow. The drive is a pleasant one—past the Temple of the Saviour, the immense cathedral with white walls and monster gold dome, built in memory of the famous incidents of 1812; along the *Pretchistinka* street, passing many of the small gaily-tinted churches and pleasantly gardened villas, which are as characteristic of Moscow as they are unlike the churches and houses of the more modern capital on the Neva; and finally, along one side of the "Field of the Virgin," by the Great Tsaritsyn-street (*Bolshaia Tsaritsynskaia*) until the clinique itself is reached. The convent makes an admirable landmark for the stranger uncertain of his way to aim at; and at a very short distance beyond are the famous Sparrow Hills, from which Napoleon first saw the gold roofs of Moscow, and which still afford the finest views to be had from anywhere of this wonderful city.

The clinical buildings nearest the town are those of the Psychiatric and the Ear, Throat, and Nose Departments; but as these lie off the main road to the left they will not at first be observed. The first clinical buildings which catch the eye are a series of two-storeyed, yellowish-white buildings on the right, running partly at an angle and partly parallel with the main road (see Fig. 5); and a taller, more ornate, red-brick structure on the left. The latter is the Children's Hospital, better known in Moscow as the Khludof Hospital, in honour of its founder, M. Khludof, who left a sum of half a million roubles (over £50,000) for the purposes of building such a hospital (see Fig. 10). Of the buildings on the right side of the road the first is a block containing the Obstetric and Gynæcological Cliniques, lying at an angle of 45 degrees with the main road, and quite close to the Church of St. Michael the Archangel, the church attached to the clinique (see Fig. 8). Continuing along the Great Tsaritsyn-street, and still on the right-hand side, will be found the Faculty Cliniques, medical and surgical, a two-winged building with a common entrance in the centre. It is the open space in front of this entrance which has been chosen as the most appropriate site for the statue of Pirogof, the unveiling of which is to form one feature of the congress week. Some distance further on is an almost identical building, containing the surgical and medical hospital cliniques. (The difference between a faculty clinique and a hospital clinique was explained in a previous chapter.) Still further is the Clinique for Skin Diseases and Syphilis, a handsome building of quite different architectural character from those already described. It is easily recognised by its corner-wise position and its brilliant white colour; it consists of a central block with Corinthian columns ornamenting its face, and two wings, one parallel and the other at right angles with the main road. The end of the "Clinical Townlet" (*Klinitcheski gorodok*), as this great series of hospitals is familiarly called, is now almost reached in this direction. Lying back from the main road on the right may be seen a side view of the Institute of Pathological Anatomy, which will be mentioned again later; and beyond this are the four detached "barracks" for the reception of children suffering from infectious diseases. This completes the list of buildings in the Great Tsaritsyn-street. Behind and running nearly parallel with it is a second series, divided from the first by another street, which, as it is not a public thoroughfare, but the exclusive property of the clinique, has not received any name. Following this road and taking the second series of buildings in the same order as the first, it may be said to begin with the Institutes of Hygiene, General Pathology and Pharmacology, all in one block, situated directly behind the Faculty Cliniques. Next to this are a number of important and useful, if less interesting, institutions—the kitchen, laundry, disinfection chambers, artesian wells, and water-tower. Still further along are the Propædeutic Wards (i.e., the preliminary clinical wards for the instruction of third-year students in the elements of clinical observation) and the Ophthalmic Hospital. A long stretch of garden is now reached, in which are some of the professors' residences and a block of dwellings for the servants and attendants. Directly facing the end of the road and bringing it to an abrupt termination is the façade of the Institute of Pathological Anatomy (already briefly mentioned), and in this same block of buildings are contained also the Institutes of Legal Medicine and of Operative Surgery.

It will be impossible, and it would, in fact, be superfluous, to describe here in detail all the wards, laboratories, lecture theatres, operating and dressing theatres, waiting-rooms, microscope rooms, Roentgen-ray rooms, bath-rooms, and offices—in a word, all the component parts of one of the completest of modern cliniques. Members of the Congress will have frequent opportunities during their stay in Moscow of seeing these for themselves, for clinical demonstrations will be held almost daily, and many of the sectional meetings of the Congress will take place in the theatres of the clinique. But some general impressions and notes gathered on the occasion of two visits to this city of the sick, and supplemented by the detailed information in the official description of the clinique published specially for the members of the Congress (for advance proofs of which thanks are due to the courtesy of Professor Klein, Dean of the Faculty of Medicine), may be of interest.

The various cliniques, general and special, differ to some extent in details, but the general principles upon which they are constructed are common to them all. They are all built on the system of separate blocks with lateral corridors. In the wards an air space has been allowed of 1489 cubic feet (45 cubic metres) per patient. The height is 14 ft. (6 *arshins*), and consequently the floor area for each bed is just over 100 square feet. In almost all the cliniques there will be found on entering a large hall or vestibule, where coats, hats, and sticks are left in charge of a *suisse*. This may seem an unnecessary statement to make, but it may not be known to some who have not visited Russia previously that on entering any building whatever, be it to make a call of only two minutes' duration, it is the unalterable custom to leave the overcoat as well as the hat and stick or umbrella in the hall. To enter a Russian dwelling-room in an overcoat is scarcely less discourteous than to enter it with one's hat on. A few steps usually lead up from the hall to the ground floor corridor, off which lead the wards and other rooms and offices. The corridors, 12 ft. in width, are features of all the cliniques. With their colour-washed walls of cream or pale blue and dado of oil-paint, with their polished oak parquet-floors, their large double windows, their comfortably warmed and artificially moistened air, and their polished pine-wood tables and benches (for the patients take their meals here), these corridors present a distinctly attractive appearance, and serve as excellent promenades for patients who are not confined to their beds. Here, as in the wards, all angles of walls, floor, and ceiling have been well rounded off to prevent lodgment of dust. A word may also be said of the broad stone staircases leading to the upper storeys, upon which, in many instances, will be found a second large vestibule or landing hung with lavishly-framed portraits of members of the Imperial family or of the "donors" of the particular clinique. The first impression upon entering the wards is one of comfort and cheerfulness. The wards are for the most part small, rarely containing so many as a dozen patients in each. The beds stand at some distance from the walls, and, at least in some wards, each of the legs of the bed is inserted into an india-rubber cup, which materially lessens the chances of jarring and external shocks. The clean white blankets are a pleasant change from the grey blankets met with in most Russian hospitals. The walls are treated in the same way as those of the corridors, and the floors are of the same oak parquet, which is thought to be as hygienic as any other material, and is certainly the most pleasant-looking of all hitherto suggested for this purpose. In all the cliniques the professor has a most comfortable and even luxurious private cabinet. In that of Professor Pospiélof, the courteous professor of dermatology, and probably in others, are two articles of furniture deserving of mention. One is a neat disinfecting chamber in which the professor's blouse (large white blouses are worn by all the staff when at work) or coat can be disinfected by dry heat in a very short time. The other is a washing-stand of French manufacture, consisting of a light plated-steel frame on rubber-covered wheels, and supporting a plate-glass basin and reservoirs for water and disinfecting solutions. It appears to be the perfection of a hygienic washing apparatus.

The wards and all the other parts of the cliniques are artificially heated by hot-water pipes sunk in the lower part of the walls. The pipes in the wards are about two inches in diameter (some of the main pipes are as broad as eight inches), and at intervals the heating surface is increased by a number of square transverse plates or wings of metal at right angles to the pipe. The water is heated by naphtha furnaces in special out-buildings. Ventilation has been carefully provided for. The foul air is artificially extracted through openings, in all cases as near the floor as possible; fresh air, warmed and moistened by a specially designed and somewhat elaborate apparatus, is admitted through grilled openings about two-thirds of the distance up the walls. In summer the large windows (of double parallel sashes 8 in. apart, like all windows in Russian buildings) can be opened and allow of a very thorough aeration of the buildings; but in a climate like that of Moscow some carefully-planned system of artificial ventilation, such as the one here briefly described, is a necessity in the long and intensely cold winter. It is but fair to add that in a visit paid to several of the cliniques late in November there was no perceptible stuffiness or draughtiness—the Scylla and Charybdis of all artificial systems of ventilation—in any of the wards; on the contrary, the air felt pleasantly warm and at the same time fresh and sweet. It is almost superfluous to state that the electric light is laid on in all parts of the clinique. The water-supply is derived from an artesian well, and a second such well is now being bored to increase the supply. The present yield of the one well is about 78,000 gallons daily. The clinique as a whole has a system of drains and sewers of its own; the sewage is carried to a large plot of land, the property of the clinique, near the banks of the River Moskva, where it is employed for purposes of irrigation.

It is impossible to close these notes upon the clinique without some reference to the fine series of operating theatres, laboratories, and lecture theatres which it contains. The so-called "Institutes," whether of Hygiene, Anatomy (see Fig. 9), or any other branch of medical science, are goodly-sized buildings containing series of well-fitted laboratories (bacteriological, biological, chemical, physical, &c.), and large lecture theatres, museums, and libraries. But there are also theatres and laboratories, and in many cases small libraries and museums, attached to the clinical buildings as well. Most of the cliniques have rooms for carrying out microscopical, bacteriological, and chemical investigations in connexion with the cases under treatment, and all have lecture theatres. The lecture theatre is generally a room well lighted from the top, and with seats for 200 or 300 students arranged in the usual amphitheatre fashion. There are many operating theatres, not only attached to the surgical wards proper, but also in some of the special departments, as, for example, the Ophthalmic, the Dermatological, and the Obstetric and Gynæcological Cliniques. As they are all more or less alike in general principle the operating-rooms of the Surgical Faculty Clinique may be taken as good typical examples. This clinique was formerly under the charge of Professor Skifosofski, and is now in the hands of Professor Bobrof. There are two operating theatres attached to it—a large and a small—the latter known as the "Laparotomy Theatre," but in reality reserved not only for laparotomies, but for all operations which involve the opening of the great cavities of the body. The large operating theatre is horseshoe-shaped, and having a large gallery in addition to the amphitheatre of seats can accommodate nearly 300 spectators. The floor is of asphalte, painted with oil paint. The table is lighted by an immense window behind it, measuring about 24 ft. in height and 13 ft. in width; this window, instead of being double like other windows is triple, a hot-water pipe passing between the two outer sashes to warm the air between them in winter. The principal articles

Digitized by Google

of furniture in the theatre are two plate-glass cupboards for the instruments; a glass table upon which to place those used during an operation; a marble basin in which to wash them after the operation; a long marble table for the dressings and other apparatus; two vessels for sterilising the instruments by means of boiling; sterilisers for preparing the aseptic dressings; and high stands for the antiseptic or aseptic solutions. The operating tables are quite simple, are constructed of either wood or zinc, and move absolutely noiselessly and imperceptibly upon rubber-covered wheels. The patient is anæsthetised in a separate room outside the theatre, and it may be added that chloroform is the anæsthetic most often employed. The so-called "Laparotomy Theatre" is much smaller than the large theatre, and students are admitted to the operations here in groups of not more than twenty at a time. There are no seats, but the floor is raised a few feet round the central space reserved for the operator and his assistants. The temperature is kept constant at 18° R. (72·5° F.) when operations are being performed. Admission to the wards of the clinique is not quite free; patients in the general wards pay a small fee of 9 roubles (less than £1) per month. Those in private wards pay from 50 to 150 roubles (roughly from £5 to £15) a month. The professors, however, have discretionary powers to admit deserving cases to the general wards without charge, provided that the number thus admitted does not exceed 40 per cent. of the total number of patients.

It may interest some readers to add here a few words as to the method by which hospitals, as a rule, are supported in Russia. It is the rare exception, if indeed any such exist, to find a hospital dependent upon the voluntary contributions of the public. In the towns the hospitals are generally supported by the municipalities. A tax of about a rouble or a rouble and a quarter per annum is levied upon all persons below a certain social position—that is to say, roughly, upon all persons of the labouring classes and servants—and this entitles those who have paid it to free treatment in the municipal hospitals. The tax is easily gathered, as under the system of passports prevailing in Russia every person's passport must be stamped by the authorities once a year, and at that time the hospital tax is paid. There is at present some talk of altering this system in St. Petersburg. It is proposed in this city to levy a general tax of 2 roubles a year upon every citizen in support of the hospitals, but the proposal is already meeting with some opposition. In the smaller towns and in the country a sufficiency of hospital accommodation is guaranteed to the artisan class by an Imperial ukase of the year 1860, in accordance with which all factories and large trade establishments are compelled to maintain small hospitals providing at least one bed to every 100 workmen, and the proprietors are forbidden to take pay of any kind from the workmen in support of the hospital. This law, however, does not apply to the capitals or to Warsaw, and it has been pointed out in a recent controversy on the subject that this tells rather unfairly on the working classes in these cities, for they are compelled to pay a hospital tax, while their fellows in the provinces are exempt from it. In the country generally the hospitals are supported by the *zemstvos* of either "government" or "district"—those local governing bodies to which frequent reference has already been made in these notes.

All these hospitals, whether supported by the State, by municipalities, or the *zemstvos*, whether founded by the charity of private individuals or by one of the great central charities briefly alluded to in an earlier chapter, are administered on the same principles—the principles laid down in the "Hospital Statute" (*Ustav létchebnuikh zavedinii*) of 1893. Under this Statute hospitals which take in more than 15 patients are divided into four classes, according to the number of beds they make up. Those with more than 300 beds belong to the first class; those with from 101 to 300 beds to the second class; those with from 61 to 100 to the third class; and the fourth class includes those with from 16 to 60 beds. The exact mode in which the institution is to be conducted, the duties of each member of the staff, the method of admitting patients, and many other matters, are defined with much exactitude in the Statute. Without venturing to enter on the impossible task of trying to compress into a small space all the complicated details of a Statute such as this, it may suffice to mention one or two facts relating to the medical staff.

The management of a Russian hospital is, to a very great extent, concentrated in the hands of the so-called *glavnui vratch*, or "head physician," a title which does not at first sight indicate what the manifold duties and responsibilities of such an office really are. The "head physician" has not only the entire control of the medical details of the hospital, but all administrative and domestic matters in connexion with it are under his direction. The office is, as a rule, only attained by comparatively senior men; the work it entails in a hospital of any size is very arduous and the responsibility great. The *glavnui vratch* always lives within the precincts of the hospital and is the real mainspring of the institution. In hospitals of the first three classes he is assisted by a hospital board (*pravlenié bolnitzui*), which consists of two of the medical men on the staff, who serve in turn, and the superintendent. The medical staff consists of "consultants," "senior" and "junior staff doctors" (using the word "doctor" as including physician and surgeon), and "ward doctors" (*palatnui vratch*) corresponding to house physicians and house surgeons. Hospitals of the first two classes have a "prosector," or pathologist, and a superintendent (*smotritel*), who has charge of the domestic arrangements and is responsible for all the stock of the hospital, except the surgical instruments. The *feldschers* have already had a chapter devoted to themselves. It only remains to mention the nurses. A great part of the nursing is done by the *feldschers;* they attend the physician or surgeon at his examination of the patients, enter his orders in a book, and transmit them to the nurses proper; they do most of the dressing of the minor surgical cases, and many of the other duties which we are accustomed to see performed by the nurses are performed by the *feldschers*. The nurses are, as a rule, called "sisters of mercy" (*sëstra miloserdii*), a title which does not, however, imply that they have taken vows or are members of any religious sisterhood, though many are attached to the Red Cross Society or other analogous associations. They are assisted in some of the rougher work of the wards by female ward attendants known as *sidiélki* (from *sidiét*, to sit), who may be defined as half nurses and half servants.

XII.

Russian Medical Celebrities of the Present Century.—The Lives of two selected.—Outline Biographies of Pirogof and Botkin.—The Pirogof Medical Society.—The Pirogof Statue in Moscow and Museum in St. Petersburg.—The Botkin Hospital and Journal.—Conclusion.

IN the history of medicine in Russia during the present century, which has of necessity been somewhat disconnectedly told in these pages, the names of many distinguished Russian physicians and surgeons are met with, whose services to the profession should entitle them to more than a mere passing mention. Such were Pirogof, Inozemtzef, Dobroslavin, Pelican, Tchistovitch, Zdekauer, Botkin, and others, to name only those who are no longer living. It is impossible here to give a detailed notice of their lives and labours; and exigencies of space will permit of a brief account of two only, the two whose names open and close the list just given and who have, perhaps, gained a wider reputation outside their own country than any of the others mentioned.

The fame of Nicolaus Ivanovitch Pirogof is assured perpetuity from the fact that his name is associated with a certain operation which he devised and practised. To most Englishmen he is probably known solely as the originator of a mode of amputating the foot; but he has, in truth, far wider claims to recognition. He was not only a great anatomist and surgeon, but he was also a most capable administrator—reformer in the best sense of the term—and an interesting and thoughtful writer. More than this, he was the first to use anæsthetics widely in military surgery; he foreshadowed the modern system of ambulances, Red Cross Societies, and aid to the sick and wounded in time of war, and he introduced nursing by women into Russian hospitals, military and civil. The facts of his life may be briefly told. Pirogof was born in 1810; he was the son of an official in the commissariat department of the army. He entered the University of Moscow at the age of fourteen, and he was only seventeen when he obtained the title of *lékar*. He at

Digitized by Google

once entered the "Professorial Institute," a kind of college which then existed for the preparation of young graduates who intended to aim at a professorial chair. Even for those times this was an extraordinarily quick career and an unusual position for one of his years. Subsequently, he was for four years Professor of Surgery at Dorpat, and in 1840 he was appointed to the chair of Hospital Surgery in St. Petersburg. He soon became one of the leading consultants of the day in the capital.

FIG. 12.

Nicolaus Pirogof, the great Russian Anatomist and Surgeon.

In 1847 the use of anæsthetics during surgical operations was introduced into Russia and the first operations performed under ether were performed by Pirogof. He published the results of his experiences with the new method in an essay, written in French, and this came to the knowledge of the Emperor Nicholas I. Russia was then at war with the Turks, and the Czar—to his eternal honour be it recorded—at once commanded Pirogof to proceed to the seat of war in the Caucasus and test the practicability of employing anæsthetics in the field hospitals. Pirogof seems to have been the first great surgeon to employ anæsthesia largely on the battle-field. He published an account of his work in this campaign in a book called "Rapport d'un Voyage au Caucase," issued in 1849. In 1848 occurred the great epidemic of cholera, the worst of the century. Pirogof, who was a keen pathologist as well as an anatomist and surgeon, made as many as 800 necropsies upon the bodies of patients who had died from cholera. Shortly afterwards he published his valuable work on "The Pathological Anatomy of Asiatic Cholera." From 1849 to 1852 he was busy in his work as professor, as director of the Anatomical Institute, and as consultant to six of the large city hospitals. The "Annals of a Hospital Clinique" was his principal literary labour at this time; and it was in this periodical, which was printed in German, that he first described the operation which has since borne his name. In 1854 his splendid Anatomical Atlas appeared, and shortly after this he was sent to the seat of war in the Crimea. He inspected all the field hospitals on the Russian side, and was himself in charge of the barrack hospitals at Simpheropol. He has left a vivid, if harrowing, description of the sufferings of the troops in the intense cold of the Crimean winter. It was his experience here, and his recognition of the many unnecessary and preventable horrors of war, which led him to propose the reforms in the direction of aid to the wounded which have already been briefly alluded to. Soon after the war he published a series of interesting and suggestive essays under the title of "Questions of Life," and among the "questions" there discussed the problems of education in its widest sense were treated at perhaps greater length than any others. It was probably the views he there expressed that led to his selection by the Emperor Alexander II. for the appointment of Curator of the Odessa Educational District—a post the nature of which was explained in an earlier chapter. After a short period he was transferred to the same appointment in the Kief district; but unfortunately his views on the relationship existing between the universities and the Government did not coincide with those of the Minister then in power. It was about this time that he published his long pamphlet upon "The University Question," in which he claimed for the universities and for the students greater freedom of literary and scientific discussion and fuller powers of self-government than they then had. The pamphlet was prohibited, and Pirogof felt himself in honour bound to resign his appointment.

In 1870 he went as the representative of the Russian Red Cross Society to the Red Cross Conference in Berlin, and at the same time he took the opportunity of inspecting a large number of the field hospitals on both sides in the Franco-Prussian war. He has left a description of this tour in a work published in St. Petersburg in 1871. Six years later the Russo-Turkish war broke out, and in September, 1877, Pirogof, though he was then sixty-seven years of age, was sent to Roumania by the Russian Red Cross Society. His experiences of this war were also published in book form on his return to St. Petersburg. In 1881 he completed his fiftieth year of public service, and although his health had already begun to fail he could not refuse the invitation of his Moscow colleagues to attend a festival organised in Moscow in his honour to commemorate the occasion. He himself knew at this time that he had not many months to live, though he hid the fact from others that he was suffering from malignant disease. He died four months later, on Oct. 27th, 1881.

Intending members of the Congress about to meet in Moscow may be glad of this outline, however brief, of the life of Pirogof, for his name will be on many lips at that time. During the Congress week in Moscow his statue, which has been raised in front of the university cliniques, is to be formally unveiled; and in the following week in St. Petersburg the new "Pirogof Museum," attached to the Army Medical Academy, the nucleus of which is the splendid anatomical and surgical collection made by Pirogof himself, will be officially inaugurated.

FIG. 13.

Professor S. P. Botkin.

Sergé Petrovitch Botkin was Pirogof's junior by many years, but their lives touched at many points. He was born in Moscow in the year 1832, and was a graduate of that University. He had not long taken his degree when, in 1854, he was commanded to the Crimea with Pirogof, where he was placed in charge of the "typh" wards—the word "typh" including all cases of both typhus and typhoid fevers. His defective eyesight, from which he suffered all his life, unfitted him for the practice of surgery, and he henceforth devoted himself entirely to the medical side of the profession. After the war was over he spent some years abroad, studying under Virchow, Rokitanski, Hoppe-Seyler, and others. He returned to Russia in 1860, and was shortly afterwards appointed to the Faculty Chair of Clinical Medicine in the Army Medical Academy in St. Petersburg. His career in the

Digitized by Google

capital was for many years one of unbroken success. He soon attained the position of the foremost consulting physician in the City. In 1872 he was appointed physician to the Court and accompanied the Empress Marie Alexandrovna, who was then ailing, to the Crimea, which he had before visited under such very different circumstances. It was in the same capacity of *leib-medik* that in 1877 he went in the suite of the Czar to the seat of war, and he has left some interesting reminiscences of what he saw of the Russo-Turkish campaign. In the following year occurred the outbreak of plague on the lower reaches of the Volga. A case presenting some suspicious symptoms was admitted into Botkin's wards in St. Petersburg, and in an unfortunate moment he let it become known that he regarded it as a mild case of plague. Something like a panic occurred in the city, and it has been necessary to record the incident here, for the storm which in consequence broke over Botkin's head and the gross and unfounded charges made against him of having spread the rumour to suit his own private ends told seriously upon his health. He suffered severely from attacks of angina; and later hæmoptysis appeared. He tried many health resorts, Russian and foreign, to gain relief, but with very partial success. His reputation in St. Petersburg had been little shaken by the incident just related, and he continued to occupy his honourable position in the profession until his death. He died at Mentone on Christmas-eve, 1889. His literary works included many essays on various clinical subjects and upon matters connected with public health. It should be added that he was the first medical member ever elected to the St. Petersburg municipality, and that he was president of the Commission appointed by the Government in 1886 to inquire into the sanitary condition of the empire and the means for improving it.

The names of both Pirogof and Botkin have since their death been attached to certain institutions founded to commemorate their labours in the cause of medicine. Even before Pirogof's death the proposal was made to form a medical society which should bear his name. Under the title of the "Society of Russian Practitioners in Memory of Pirogof" this has since become the most representative of all Russian medical societies. Conferences lasting eight days are held under its auspices, at intervals of from one to three years, in one of the capitals or more important provincial towns; and these meetings are attended by large numbers of medical men from all parts of the empire. The society is, in fact, in not a few points closely analogous to the British Medical Association.

The memory of Botkin is perpetuated by the name of one of the most important of the municipal hospitals in St. Petersburg, known as the "Barrack Hospital for Infectious Diseases in Memory of Botkin," and by the fact that a medical journal is published weekly in St. Petersburg under the title of *The Botkin Hospital Gazette* (*Bolnitchnaia Gazeta Botkina*).

With this condensed account of the life and work of two great representative Russians, surgeon and physician respectively, the present notes upon the past and present of medicine in Russia may fitly come to a close. The lives just told may be taken as types of the lives, *mutatis mutandis*, of the Russian physicians and surgeons of to-day, with many of whom Englishmen who go to the approaching Congress will have an opportunity of becoming acquainted, but of whom it would be an impertinence to speak here in terms of eulogy. Brief *curricula vitæ* of some of the more distinguished Russian medical men of the day, more particularly of those officially connected with the Congress, have already been given in the notes upon the Twelfth International Medical Congress. But if living individuals may not be praised, living institutions may; and of the medical institutions of Russia it may truly be said that they are worthy of the great country which has given them birth, of the great people by which they are supported, and of the great profession which has brought them to their present admirable state of development.

"FLOREAT MEDICINA ROSSICA."

midst, but it may be that ere we succeed in bringing about its total extinction an increased phase of activity of the virus will show us some weak spots in cities other than Liverpool and Dublin.

DR. H. R. SILVESTER: AN UNREQUITED BENEFACTOR.

IT unfortunately happens only too often that benefactors of their fellow men fail to obtain any personal reward or distinction for the important services which they have rendered. A conspicuous example of this kind has lately been suggested to us by a correspondent in the course of a letter on the "Silvester method" of restoring persons after apparent death from drowning and other causes of asphyxia. There can be no doubt that the community has benefited immensely by Dr. Silvester's discovery, the Royal Humane Society alone having recorded hundreds of instances in which it was the means of saving the lives of persons who were to all appearance drowned. Not only the Royal Humane Society, but the Admiralty, the Board of Trade, the Emigration Board, the Coast Guard Service, the National Lifeboat Institution, and various life-saving societies, both in this country and abroad, have approved of the method and directed it to be used by their officials, and in various publications have carefully described the details of the process for the information of seafaring men and the world at large. Dr. Silvester, however, has received only one recognition of his services to the public, the Fothergill medallion, awarded by the Royal Humane Society, a high honour it is true, but the circumstances are exceptional, for the lesson which Dr. Silvester has taught is one to be learned, not only by the medical profession, but by the thousands whose business or pleasure leads them into positions where life may be lost by drowning. The "Silvester method" is, in fact, one of the most useful of life-saving devices, its discoverer happily is still with us, and the present time, when he is retiring from the practice of his profession, would seem to be a fitting occasion for some public appreciation of his valuable work.

MR. RALPH STOCKMAN, M.D., F.R.C.P. Edin., F.R.S. Edin., who has been appointed to the chair of Materia Medica and Therapeutics in the University of Glasgow by the Crown, in room of the late Professor Charteris, holds the position of Lecturer on Materia Medica and Therapeutics in the Edinburgh Extra-mural School, and is Examiner in Materia Medica in the University of Oxford. He has also held the post of Examiner in the same subjects at Victoria and Glasgow Universities.

THE date of delivery of the Bradshaw Lecture by Dr. Markham Skerritt has been fixed for Nov. 4th, 1897. On Nov. 11th Dr. Pavy will deliver a lecture supplementary to his previous Croonian Lectures. The Gulstonian Lectures for 1898 will be delivered by Dr. J. Rose Bradford, the Lumleian Lectures by Sir R. Douglas Powell, and the Croonian Lectures for 1899 by Dr. J. B. Bradbury.

AMONG their appointments to Science Research Scholarships Her Majesty's Commissioners for the Exhibition of 1851 have placed the name of William Alexander Osborne, M.B., of Queen's College, Belfast. These scholarships are of the annual value of £150 and are tenable for two years, and, under special circumstances, for three years.

THE Treasury have appointed a small committee to consider and report upon the desirability of establishing a National Physical Laboratory for the testing and verification of instruments for physical investigation and for other similar purposes. Lord Rayleigh will be chairman, and with him are associated several leading physicists.

AT the Viceregal Lodge, Dublin, on Aug. 2nd, his Excellency the Lord-Lieutenant conferred the honour of knighthood on Mr. George F. Duffey, M.D. Dub., President of the Royal College of Physicians of Ireland; and on Mr. William Thomson, M.D. Q.U.I., President of the Royal College of Surgeons in Ireland.

ENGLISH visitors to the Moscow Congress who may avail themselves of the opportunity of passing through Hamburg are assured of a welcome by the profession there. In another column we publish a letter by Dr. Kümmell, of the Allgemeines Krankenhaus in Hamburg, on this subject.

WE have received from the Foreign Office a Programme of the Conference which is to be held on the subject of Leprosy at Berlin from Oct. 11th until Oct. 16th next. Intending members should communicate with Dr. E. Ehlers, 6, Lanegarde, Copenhagen.

AT a meeting of the Council of the Metropolitan Hospital Sunday Fund held on Thursday, Aug. 5th, at the Mansion House, the sum of nearly £40,000 was recommended to be paid to 132 hospitals and 56 dispensaries.

SIR CHRISTOPHER NIXON, M.D. R.U.I., has been appointed Representative of the Royal University of Ireland on the General Medical Council, in lieu of Sir John Banks, resigned.

THIRTY-FIVE duly qualified medical practitioners have applied for the post of superintendent of the Aberdeen Royal Infirmary.

THE London University Commission Bill has shared the fate of other opposed measures and has been withdrawn.

Pharmacology and Therapeutics.

TREATMENT OF HYDROCELE BY CARBOLIC WATER.

WHAT appears to be both a simple and effective method of dealing with hydroceles has been practised for the last couple of years by Dr. Pilate and Dr. Vissemans in the Orleans Military Hospital. It consists in the washing out of the cavity of the tunica vaginalis—after evacuation, of course—with a weak solution of carbolic acid. The surface is first cleaned with soap and brush and then washed with a solution of perchloride of mercury. The trocar is then inserted, and after the serous fluid has been drawn off warm carbolic water of the strength of 3 per cent., which has been previously boiled, is injected. This is allowed to come out, and is seen to be turbid, containing fibrinous flocculi. The washing out is repeated four or five times until the liquid emerges from the cannula quite clear. The instrument is then withdrawn and the puncture closed in the usual way, a suspensory bandage being put on. Owing to the anæsthetic effect of the carbolic acid the patient feels no pain. Some further effusion into the sac usually occurs in four or five days, but this soon subsides and the patient can resume his ordinary work. He is advised, however, to continue to wear the suspensory bandage for a time. This treatment has proved quite satisfactory, but is only recommended in simple cases occurring in young subjects.

NUTRITIVE EFFECT OF SUBCUTANEOUS INJECTIONS OF OIL.

Dr. Fornaca and Dr. Michell, of Professor Bozzolo's clinic in Turin, have made a series of trials of the effects to be obtained by injecting oil under the skin. They find that a dose of from 30 to 200 grammes introduced in this way is rapidly absorbed, and that it produces a marked decrease in the quantity of nitrogen eliminated, thus of course allowing more to remain in the tissues without undergoing metabolic change, the body weight increasing and the general condition being improved. It would appear that oil introduced subcutaneously has much the same nutritive value as when it is ingested, and produces better effects that when it is injected per rectum. Indeed, it seems to these investigators that the hypodermic might be substituted for the rectal method in most

Digitized by Google

of the cases in which the latter is usually employed. Two of the subjects on whom observations were made were suffering from diabetes. In one of these cases 1780 cubic centimetres were injected in the course of thirteen days, and produced a remarkable diminution in the quantity of nitrogen eliminated and in the amount of sugar excreted, together with a slight increase in the body weight. No alteration was found in the quantity of urine passed. In the other case it was not possible to inject more than 310 grammes in four days, but even this small amount produced some decrease in the amount of nitrogen eliminated.

RECTAL FEEDING IN TYPHOID FEVER.

For some time past Dr. Queirolo, Professor of Clinical Medicine in the University of Pisa, has been in the habit of feeding his cases of typhoid fever entirely by the rectum in order to afford the diseased bowel complete rest. The nutrient enemata are given four times daily, and consist of triturated meat and pancreas with a few drops of laudanum, each injection being preceded by irrigation of the bowel with boracic acid—the plan, in fact, advocated by Leube. The patients are allowed to drink hydrochloric acid lemonade. In this way the digestive tract is preserved from putrescible substances, and this Dr. Queirolo considers obviates one of the most fruitful sources of auto-toxic action. All the cases treated on this system, many of them of a very severe type, are stated to have recovered.

The Lancet Special Commission
ON
SICILY
AS A HEALTH RESORT.

V.[1]

Consideration of the Suitability of Sicily as a Health Resort for cases of (1) Bronchitis and Bronchial Asthma; (2) Laryngeal Affections; (3) Impaired Convalescence; (4) "Scrofula" and "Lymphatisme"; (5) Senile Affections; (6) Anæmia and Chlorosis; (7) Nervous Diseases; and (8) Phthisis.—Sicily as a Summer Station.—Gibilmanna.—Accommodation in Sicily.—Deficiency of Artificial Attractions.—Question of Brigandage—Season for Visiting Sicily—Richness of Sicily in Matters of Historic and Antiquarian Interest.—Renan and Goethe.—Concluding Remarks.

IN the previous articles the data—meteorological and botanical—for forming a correct estimate of the climate of Sicily have been sufficiently set forth. It was found that the climate was intermediate between that of Europe and Africa, and that its leading characteristics were warmth, mildness, brightness, breeziness, equability, and moderate humidity, and that the proportion of fine weather, free from extremes, was remarkably high. It was further pointed out that the physiological action of the climate upon the human organism might be described as (1) moderately tonic and (2) sedative. It remains to inquire in detail what are the morbid conditions likely to be benefited by a temporary residence in Sicily—or, in other words, what is the special utility of the island as a health resort. The following statements embody the experience and opinions of the leading Sicilian physicians who have been kind enough to furnish THE LANCET Special Commissioner with their views.

(1) *Bronchial affections, especially the dry and irritable varieties, and including bronchial asthma*—All authorities are unanimous that these affections do exceptionally well in Sicily. That is a conclusion which theoretical considerations would strongly suggest, and which practical experience is found to corroborate. A climate which is warm without extreme heat, neither excessively dry nor excessively humid, almost exempt from frost, snow, and cold winds, and which presents a remarkable degree of diurnal, mensual, and annual equability would naturally suggest itself as highly favourable for bronchial affections Further, the unquestionably sedative influence of the climate upon the nervous system adds the additional element which is desirable in bronchial affections of an irritable or spasmodic type. On the other hand, cases of bronchitis attended by profuse secretion, whether or not amounting to actual bronchorrhœa, do not progress favourably in Sicily, inasmuch as they require a drier atmosphere. Bronchial asthma is well known to be a most erratic affection, for which it is difficult to select a suitable climate, but all the Sicilian observers are unanimous that, on the whole, it does well in Sicily.

(2) *Laryngeal affections.*—The remarks just made with regard to bronchial affections may be substantially repeated with regard to laryngeal affections. The dry and irritable varieties do extremely well in Sicily—the moist varieties do not do well. Tuberculous laryngitis will be considered in connexion with phthisis.

(3) *Impaired convalescence after wasting diseases, after-effects of the specific fevers, malaria, bone and joint diseases, pneumonia, pleurisy, &c.*—This large class of patients on the whole do well in Sicily. The mildly tonic influence of the climate seems to promote the recuperative processes without stimulating the dregs of these diseases to renewed activity. The large proportion of mild, sunny weather permitting regular exercise almost daily is much in favour of these cases. Convalescents sufficiently advanced towards recovery to require a distinctly bracing climate should not be sent to Sicily.

(4) *"Scrofula" and "lymphatisme."*—These cases do well in Sicily for reasons analogous to those which render the climate favourable for convalescents. As regards British patients of this class, only the more delicate cases are suitable for Sicily. The more robust patients will generally be found to do better at Margate, Broadstairs, Folkestone, or perhaps Biarritz.

(5) *Senile affections*—These cases do well in Sicily, the warmth and equability of the climate and its mildly sedative influence being highly favourable to them. Elderly patients, who are free from grave organic disease, but who feel the weight of years and are depressed by the gloom and cold of the British winter, would in most cases benefit decidedly by wintering in Sicily. The bronchitis and dyspepsia from which they so often suffer would be relieved, and the generally mildly tonic influence of the climate suits their case. These patients are often sent to the Riviera, and frequently with benefit, but the Riviera climate is too exciting for many of them—insomnia resulting—and the mistral tries them severely.

(6) *Anæmia and chlorosis.*—These cases do well in Sicily, the large amount of sunshine and ample facilities for outdoor exercise promoting digestion and sanguification.

(7) *Irritable nerve affections, including hysteria and neurasthenia.*—These cases are likely to benefit by the mildly sedative influence of the Sicilian climate. The great scenic attraction of the island and its historic and antiquarian interest may prove valuable in certain cases of nerve disorder. Insomnia will probably be favourably affected.

(8) *Phthisis.*—This disease requires somewhat fuller consideration for various reasons. It is the chief disease for which climatic change is usually sought, its climatic treatment is admittedly a very difficult matter, and the Sicilian physicians are not unanimous regarding the results obtained at the Sicilian sanatoria. It has been shown that phthisis is common in Sicily, but that its prevalence is below the general European average, and Professor Ugetti's remarkable figures tending to show the comparative exemption of Catania have been given, although they cannot be regarded as in any sense final and conclusive. The Sicilian practitioners in general are guarded in their statements respecting the results of treatment obtained among foreign phthisical patients wintering in Sicily. Many cases would appear to do well, some very well, and even the least promising cases—e.g., laryngitis tuberculosa—are sometimes relieved, but the general results are doubtful in nature, and the suitability of the climate for phthisical patients is still a moot point. Where practical experience speaks with doubtful voice it is fair to inquire what light can be thrown on this important subject by the general principles known to apply to the climatic treatment of phthisis. Are there cases of the disease likely to benefit by wintering in a climate characterised by warmth, mildness, equability, moderate humidity, &c., or not? Are there cases, on the other hand, upon which the effect of such a climate will be either neutral or injurious? These questions admit of a more or less definite answer. The ground may be somewhat cleared by

[1] Nos. I., II., III., and IV., were published in THE LANCET of June 5th and 12th, and July 3rd and 24th, 1897, respectively.

Digitized by Google

laying down the principle that cases of phthisis likely to be benefited by the Alpine sanatoria should not be sent to Sicily. If the disease be early, limited in extent, and not very active; if the general constitutional state be fairly good; if the vascular and digestive systems are sound; and if there be no general bronchitis, rheumatism, or nervous disorder—then the patient should in most cases be sent to a distinctly tonic climate such as Davos, the South African Highlands, or Colorado. But it must be admitted that the above type of case forms only a small minority of phthisical patients. The majority of these cases present either marked constitutional debility, or activity of the tuberculous process or serious digestive defect, or bronchial, cardiac or nervous complications; and where such symptoms are present the recommendation of the elevated sanatoria is distinctly perilous, although even in the most unlikely cases a brilliant success may sometimes be obtained. Excluding from consideration those cases of phthisis where for various reasons climatic change must be altogether prohibited, there remains a large class where general or digestive debility, anæmia, low vascular tone, bronchial irritability, nerve disorder, or some other cause, precludes resort to the elevated sanatoria. In such cases the choice at present rests in most instances between the sea-voyage, the Riviera, Madeira, and the Canary Islands, the North African sanatoria, viz., Egypt, Algiers, and Tunis, or the Australasian colonies. The question arises whether in a certain proportion of such cases Sicily might be tried with benefit. It is probable that good results might be obtained in the following varieties of phthisis—viz.: (*a*) Early phthisis complicated by anæmia, low vascular tone or nervous irritability. In such cases the tonic and soothing qualities of the Sicilian climate might be expected to act favourably. (*b*) In cases of phthisis of the catarrhal variety. The admitted efficacy of the Sicilian climate in bronchial conditions would suggest its suitability for catarrhal phthisis. (*c*) In cases of laryngitis tuberculosa. In such cases the prognosis is always grave and usually very bad, but the soothing qualities of the Sicilian climate and its well-known utility in irritable laryngeal states render the prospect of some temporary benefit fairly hopeful. Experience has shown that this expectation is sometimes justified by the event.

Among the diseases upon which the influence of the Sicilian climate is, on the whole, injurious may be mentioned rheumatism and renal affections. Ophthalmia in many of its forms might be added to these.

Some not unimportant differences exist between the various Sicilian localities with regard to their suitability to different states of disease. For bronchial, laryngeal, and irritable nervous affections it is probable that Palermo and its vicinity offer the greatest advantages. For phthisis the environs of Catania and Acireale would seem most suitable. For convalescents from acute diseases Taormina offers unrivalled attractions. In most of the other morbid conditions enumerated as likely to benefit by the Sicilian climate the choice of special localities is probably unimportant. Syracuse is, on the whole, unsuitable for a health resort. Girgenti has not hitherto been much frequented by invalids, but it has considerable claims to attention from the point of view of climate and may have a future before it.

The above remarks apply more particularly to Sicily as a winter resort, but there can be little doubt that the island offers considerable attractions as a summer station—especially for residents in Algeria, Tunis, and Egypt. The slopes of Mount Etna and of the Madonian mountains present almost every grade of temperature and variety of climate, and a summer sanatorium might easily be founded in one or other of these localities. The Marchese di Gallidoro writes as follows to THE LANCET Commissioner: "Of all places in Sicily that have been proposed as an Alpine climatic station I think the most suitable is Gibilmanna (Mountain of the Manna, from the manna tree, Fraxinus ornus, which from time immemorial has been largely cultivated on its slopes). It can be easily reached from Palermo by taking the train (one hour) to Cefalù, whence a tolerably good mule path leads to Gibilmanna in an hour and a half. The Capuchin convent and shrine of the Madonna are about 900 metres above the sea level. In close proximity there is an extensive plantation of stately oak trees, and close by rises Pizzo S. Angelo, between 1200 and 1300 metres high, which may be considered as an isolated eminence on a spur of the great Madonian range, and can be reached in about an hour's easy walk. There is an abundant supply of fresh water, the view is as extensive as it is beautiful and varied, and the climate is as fresh, healthy, and invigorating as can be desired." The question of establishing a sanatorium in Silicy for invalided soldiers and civilians from Egypt, Malta, and perhaps India has been more than once mooted, and is deserving of serious consideration. There seems every reason to believe that in Taormina there is to be found a sanatorium of exceptional value for convalescents from malaria, the specific fevers, inflammatory affections of the lungs and pleura, wounds, accidents, &c. When it is remembered that Taormina is about twelve hours' journey from Malta, its convenience and accessibility are manifest.

Sicily is well adapted to serve as an intermediate station for patients *en route* to or from Tunis or Egypt. Especially does this apply to patients who have wintered at Luxor, Helouan, or Cairo, and who find themselves compelled to leave in the month of March. To cross the Mediterranean directly at this season and face the abrupt climatic change which this involves is in many cases imprudent and undesirable, and the selection of a suitable intermediate station has long been a matter of great difficulty. Sicily may be recommended with confidence as well suited to cases of this kind. March is an excellent month there, and April is also good. The patient who has just come fresh from the sublime remains of ancient Egyptian art will find much to interest and instruct him in Sicily, and in no other way can he so safely and so pleasantly bridge over the gulf between the climate of Egypt and that of the Riviera, Pau, Biarritz, or Arcachon. Breaking their homeward journey in Sicily may be safely advised as a good routine rule for patients who have wintered in Egypt.

The question of the nature and amount of the accommodation to be found in Sicily can be touched on only very lightly here. On the whole, the traveller will probably be agreeably disappointed on this score. In Palermo there are a number of hotels of the first-class where the tourist or invalid can count upon every comfort and attention. In Girgenti, Catania, and Taormina the accommodation is also good. The great "bath establishments" of Termini-Imerese and Acireale are comfortable and well-equipped. On the other hand, in most of the small towns and country places the accommodation is often of the most primitive description, and the average Sicilian inn is not to be lightly ventured upon, even by the seasoned traveller, still less by the invalid. The national standard of cleanliness is not high, and the mildness of the climate is only too favourable to insect life. In special provision for the wants of invalids Sicily at present is very deficient. "Pensions" are few in number and not usually comfortable or adapted to the needs of the ailing, and furnished apartments are not, as a rule, organised to meet the wants of the invalid. In these points, however, efforts are being put forth to remedy existing defects, and it may be expected that substantial progress will soon be made. What is most required is a number of "pensions" or small private hotels, removed, if possible, from the great centres of population, and situated in quiet, airy, and healthy localities. In such institutions the special wants of *poitrinaires* or other invalids could be met, and the mode of life arranged for their benefit in a way which is impossible in a large hotel where the great majority of visitors are healthy people. The environs of Palermo and Catania present many spots particularly well suited for institutions of this sort, and Girgenti and Taormina also offer unusual advantages.

Sicily is deficient also in those attractions which go far to make the fortune of such resorts as Homburg and Spa, Nice and Monte Carlo—viz., the Kursaal, the Casino, the racecourse, the fashionable promenade, the bands of paid musicians. This is not an unmixed disadvantage, perhaps, inasmuch as the pursuit of health and the pursuit of pleasure are not easily compatible. The gaiety of life upon the Riviera, for example, does not add to its utility as a resort for serious invalids, while no doubt increasing its attractiveness to the holiday maker and pleasure seeker. But there is a mean to be observed in this, as in most other things. A sanatorium should not be a centre of dissipation, neither should it be given up to dulness and gloom. Disease and absence from home are depressing; time hangs heavily on the invalid condemned to an enforced and unwelcome idleness; hence some provision for reasonable and healthful amusement is indispensable for every health resort, which aspires to hold its own amidst the ever-increasing number of rival sanatoria. Parks with sheltered walks, where good music could be heard at stated times, clubs, libraries, and

Digitized by Google

reading-rooms, tennis courts, and golf-grounds; these are a few of the measures which naturally suggest themselves in this connexion.

It would not be possible to deal exhaustively with Sicily as a health resort and omit all reference to a matter which naturally arises to the mind of the English reader in association with the island—namely, the subject of brigandage. On this question a great deal of misconception exists, and Sicily is now suffering in repute for events which belong to the past, rather than to the present. Broadly speaking, it may be affirmed that while the security of life and property in Sicily is below the general European average, and leaves much to be desired, organised brigandage has practically ceased to exist in the island. Crimes of violence (especially the use of the knife)—the result of family feuds, love quarrels, and starvation—are common in Sicily, and the offender often takes to the mountains, sometimes associating there with others in like plight, but this is for the most part the worst that can be said. Count Mazzarino informed our Commissioner that he had been in the habit for years of visiting all parts of Sicily, even the most remote, unarmed and unattended, and that he had never been molested in any way. A prominent Englishman recently drove all over the island, with his wife, in an open carriage without escorts and had no reason to regret his hardihood. All information tends to show that even in past days, when brigandage was admittedly an evil of great magnitude, tourists and foreign visitors were in no case molested. The real victims were wealthy residents who were known to the brigands, and for whom a substantial ransom might be expected.

The choice of season for visiting Sicily will depend upon the objects and state of health of the traveller. To those who propose to winter in the island an arrival in the early days of November may be recommended, and the date of departure may be safely postponed until the end of April or the beginning of May. Travellers for pleasure only will find February, March, and April the most suitable months. At that season, as already stated, the weather in Sicily is often the best in Europe, being for the most part bright and mild without cold winds or extremes of temperature. The amount of rain varies within wide limits, and is sometimes considerable. The early autumn (September and the first half of October) is not a favourable time for visiting Sicily, but the latter part of October and the month of November may be chosen, although much less suitable than the spring months.

In the selection of a sanatorium climatic and hygienic questions no doubt claim the first place, but they are not the only points worthy of consideration. The general attractiveness of a locality, the facilities it affords for recreation, study or research, the distractions which it can offer to the traveller or invalid—these are matters of great, and in some cases (e.g. nervous invalids) of primary importance. From this point of view Sicily takes a high place in the front rank of European sanatoria. It would be difficult to name any locality in Europe which combines so much natural beauty with such wealth of historic and antiquarian interest or which unites so many points of interest to any educated individual. The following sentence of Renan may here be recalled: "Je l'avoue, il me serait impossible de résider ou même de voyager avec goût dans un pays où il n'y aurait ni archives ni antiquités. Ce qui fait l'intérêt et la beauté des choses, c'est le cachet de l'homme qui y a passé, aimé, souffert." (I declare that it would be impossible to me to live or even to travel with pleasure in any country which possessed neither history nor antiquities. What really gives interest and beauty to things is the mark that there man has been, that there he has loved and suffered.) From this point of view Sicily is almost unique. Her history is one of the most ancient, chequered, and pathetic which human annals present. Her remains of antiquity are among the most extensive and the most moving in the world. As the traveller stands in front of the great temple of Segesta and beholds the majestic ruin standing amidst a scene of indescribable loneliness, or as he climbs the precipitous streets and narrow alleys of modern Girgenti and thinks of the grandeur of ancient Acragas, "the most beautiful city of mortals," as Pindar calls it, or as he takes his place in the Greek theatre of Syracuse and surveys the ruin and desolation around him, the great harbour, in the distance the purple Ionian Sea, and on the northern horizon the snowy dome of mighty Etna—he feels that nature and art, history and myth, poetry and romance have combined to make Sicily an enchanted land. Subtle suggestions of the south arise to heighten the impression. Wherever he goes in Sicily he is reminded that just below the southern horizon lies the great Dark Continent. The waving date-palm and the prickly pear, the Moorish arch in the cathedral, and the Saracenic water-tower by the wayside, the careless grace with which the peasant bestrides his mule, recalling the Kabyle or the Bedouin, the touch of negroid type in an occasional face, the breath of the sirocco—these speak of Africa and of the desert. Many of the greatest minds have felt the subtle charm of Sicily. Homer sang its praises in the dim dawn of poetry, although the vagueness of his references make it improbable that he ever visited the island. The trumpet tones of Pindar proclaimed its glories to a later age. Virgil and Cicero, and in modern times Goethe and Schiller, have written of Sicily. There is a tradition that the first suggestion of Mignon's song came to Goethe as he stood upon the terrace of the church of San Gregorio, which overlooks the straits of Messina. Whether or not this tradition be true, there can be no doubt that this song is full of the odour and subtle suggestion of Sicily and of the South—especially in its opening verse:—

"Kennst du das Land, wo die Citronen blühn,
Im dunkeln Laub die Gold-Orangen glühn,
Ein sanfter Wind vom blauen Himmel weht,
Die Myrte still und hoch der Lorbeer steht?
Kennst du es wohl?
Dahin! Dahin
Möcht' ich mit dir, o mein Geliebter, ziehn."

"Know'st thou the land where lemon trees do bloom,
And oranges like gold in leafy gloom;
A gentle wind from deep blue heaven blows,
The myrtle thick, and high the laurel grows?
Know'st thou it, then?
'Tis there; 'tis there,
O my beloved one, I with thee would go:"
(*Carlyle's translation.*)

Sicily has passed through much racial strife and many dynastic vicissitudes. Her troubles at present are chiefly economic. The tyrant is gone, perhaps for ever, but the tax-gatherer remains. Poverty abounds in the island and even the pale shade of starvation is not far off. But in many things there is progress, and above all the general advance in education is marked and unmistakeable. The seed is being sown, and the harvest—even if late—will some day appear. May the charming island renew something of her ancient glory and once again become the abode of a prosperous, happy, and contented people.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

(*Concluded from p. 278.*)

WE may next deal with the representative display of foods and food products. Here, perhaps, the Aylesbury Dairy Co., of 31, St. Petersburgh-place, W., were to the fore. Their stall included such well-known preparations as humanised milk, peptonised milk, sterilised milk and cream, sterilised food for infants, cream milk for infants, and Koumiss of varying degrees of fermentation. Next should be mentioned the great number of laboratory products which formed the chief feature of Messrs. Armour and Co.'s (59, Tooley-street, S.E.) stall; this included the animal ferments, desiccated powder, tablets of animal substances, thyroid tablets, and concentrated extract of beef, with and without beef fibre. Messrs. Beanes and Co., of Wallace-road, Hackney Wick, N.E., brought to the notice of the visitors their excellent preparation known as "Diastased Farina," which by itself possesses digestive properties and is therefore well adapted as a food for infants and invalids. Messrs. G. Van Abbott and Sons, of 6, Duke-street Mansions, Grosvenor-square, W., showed samples from their very comprehensive list of foods for the diabetic. The preparations of interest to medical men in the exhibit of Messrs. Sadler, Firth and Ross, of 26, Gt. Guildford-street, S.E., were mustard oil and mustard bran for medical application. In addition this firm showed excellent specimens of the condiment. Of the recent additions to the list of really good beef preparations must be reckoned Vimbos prepared by the Vimbos Co., of 130, Queen Victoria-street E.C.; one marked property this fluid preparation possesses being its excellent flavour. We have already described the humanised milk

Digitized by Google

prepared by Dr. Gaertner's process.[1] The resulting product contains a soft flocculent curd in an easily assimilable state, while the sterilising process is not carried too far. Samples were shown by the Friern Manor Dairy Farm, Ltd., of 20, Farringdon-street, E.C. Some choice cereal preparations adorned the stall of Mr. B. Lampe, of 181, Queen Victoria-street; they were all characteristic in size and quality of American growths. The well-known preparations of the Liebig Extract of Meat Co., of 9, Fenchurch-avenue, E.C., were submitted for inspection and trial, while Messrs. Broomfield and Co., of 83, Upper Thames-street, E.C., described the advantages of Albene, a pure refined vegetable fat which is said to be easy of digestion, and not liable to become rancid. It is stated to be useful in cooking, and also as a suitable ointment base. The first malt extract ever prepared (Leopold Hoff, 29, New Bridge-street, E.C.) found a place in the exhibition. It presents the active and nutritive quantities of malt in a fluid and agreeable form. On Messrs. Mellin's (Stafford-street, Peckham, S.E.) stall were to be seen their well-known foods for infants and invalids, which consist largely of food products partially prepared for easy assimilation by the action of diastase. The exhibit also included an emulsion of cod liver oil and hypophosphites. An attractive assortment of diabetic foods was presented by Messrs. Callard and Co., of 65, Regent-street, W., while not far away were the Hovis preparations of flour, bread, and biscuits of Messrs. S. Fitton and Son, Macclesfield. An excellent idea of the improvements which modern investigation has required at the hands of those responsible for the quality and purity of our dairy produce, could be gained by an inspection of the excellent exhibit of Messrs. Welford and Sons, of Elgin-avenue, Maida Vale, W. Then should be mentioned the great number of Bovril preparations exhibited by the Bovril Co., of 30, Farringdon-street, E.C., and, also, the excellent food and milk prepared by Henri Nestlé, of 48, Cannon-street, E.C., and the preparations of the Anglo-Swiss Condensed Milk Company, of 10, Mark-lane, E.C., which are guaranteed to contain a maximum of cream.

We may now briefly review the mineral and medicinal waters that were exhibited in addition to other allied products and the appliances connected therewith. Messrs. Ingram and Royle, of 26, Upper Thames-street, E.C., made an excellent display of the many natural mineral waters for the sale of which they are the agents. Thus were shown the various natural mineral waters of Vichy, the Carlsbad salts, and Hunyadi Janos. An excellent illustration of the improvements recently brought to bear upon the manufacture of aerated waters was shown in the exhibit of Messrs. Idris and Co., of Camden Town, N.W., the purity of the aerated waters of this firm being well known. Not far off was an interesting exhibit by the Compressed Gas Co., Ltd., of 181, Queen Victoria-street. Here were shown machines for directly converting any liquid placed in a bottle into an aerated beverage. The machines are suitable for domestic and general use, and are useful for aerating milk. Included in the same exhibit was an icing and cooling apparatus by means of carbonic acid gas. Both would be valuable for hospital use. What is described as a new natural mineral water for use in the treatment of gout and gouty diathesis and sundry diseases of the kidneys and bladder is the water from the "Kronenquelle" exhibited by Messrs. W. Schacht and Co., of 27, Finsbury-pavement, E.C. The Holyrood Table Water, prepared by Messrs. Macfarlan and Co., of 9, Moor-lane, E.C., is worthy of mention as a new artificial water introduced by this firm the composition of which is founded on analyses of the best imported waters. The aerated waters prepared by the Chemists' Aerated and Mineral Waters Association, of Gifford-street, Caledonian-road, N., were brought prominently to the notice of the visitors in the vestibule of the hall, where huge syphons were displayed illuminated from the interior by red electric glow-lamps.

Lastly, a very important exhibit—which was allotted especial space in a room adjoining the hall, and one which deservedly attracted considerable interest—was that of the West-end Pathological Laboratoty, under the control of Mr. Severn and Mr. Groth, the secretary. This consisted of numerous characteristic pure cultivations of bacteria in various nutrient media, besides a collection of mounted slides of some of the rarer micro-organisms under oil immersion lenses. Among these the preparations of the organisms occurring in diphtheria, trachoma, bubonic plague, catarrhal ophthalmia, and certain hair and skin fungi were especially to be commended. Mr. Severn also showed some accurately coloured drawings of pathogenic bacteria and excellent photo-micrographs and radiographs. Amongst the novelties of this exhibit were also the demonstrations by Mr. Townsend of Dr. Oliver's hæmoglobinometer and cytometer, and of the Tintometer Company's other apparatus.

[1] THE LANCET, July 3rd, 1897, p. 26.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE quarterly Comitia of the Fellows was held on July 29th, the President, Sir SAMUEL WILKS, Bart., being in the chair.

It was announced that the Gulstonian Lectures for 1898 would be delivered by Dr. J. Rose Bradford, the Lumleian Lectures by Sir R. Douglas Powell, and the Croonian Lectures for 1899 by Dr. J. B. Bradbury. The date of delivery of the Bradshaw Lecture by Dr. Markham Skerritt this year was fixed for Nov. 4th, and on Nov. 11th Dr. Pavy will give a lecture supplementary to his previous Croonian Lectures.

On the motion of the Senior Censor (Dr. Church) the hearty congratulations of the College were voted to the President upon the honour conferred upon him by Her Majesty. The vote was carried by acclamation, the Fellows standing. It was acknowledged by the President in suitable terms, attributing the honour to the office to which he had been called by the votes of the Fellows.

The following gentlemen were admitted to the Membership of the College:—Donald John Armour, B.A., M.B. Toronto; Francis Henry Edwards, M.D. Brussels; Robert Hutchison, M.D. Edin.; Alexander McGregor, M.D. Aberdeen; and Arthur Francis Stabb, M.B. Camb.

The PRESIDENT announced that the Treasurer (Sir Dyce Duckworth), Dr. Pavy, and Dr. Lauder Brunton would represent the College at the forthcoming International Medical Congress at Moscow.

Licences were granted to the 146 candidates who were successful at the recent examination, and the diploma of Public Health of the two Colleges was granted to those who had passed the examinations for that purpose.

On the invitation of the President the Registrar read an account of the proceedings attending the admission of H.R.H. the Prince of Wales to the Honorary Fellowship.[1]

A communication was read from the Home Secretary stating that Her Majesty had been graciously pleased to accept the address presented by the College on the occasion of the completion of the sixtieth year of Her Majesty's reign.

Communications were read from the Secretary of the Royal College of Surgeons of England reporting the proceedings of its Council.

A communication was read from the Educational Committee of the Medico-Psychological Association, enclosing a Syllabus of Instruction in the subject of Insanity approved by the committee. On the motion of Dr. Norman Moore, seconded by the Senior Censor, the syllabus was referred to the committee of management for transmission to the examiners.

A communication from Dr. R. R. Rentoul forwarding a copy of his Draft Bill for the Registration of Midwifery and other Nurses was received.

A communication from the Foreign Office was read enclosing documents received through the German Ambassador upon the subject of an International Conference on Leprosy which is to assemble in Berlin in the month of October. The programme of the proceedings was forwarded with an expression of the hope that its contents would be made known to the medical profession in this country, who are invited to share in the Conference.

The PRESIDENT announced that the London University Commission Bill, which had just passed through the House of Lords, had been considered by the Standing Committee of the College upon the university question, and also by the delegates of the two Royal Colleges, and it was a question whether it might not be advisable for the College to pass a resolution expressing approval of the measure, in order to

[1] Vide THE LANCET, July 31st, 1897.

Digitized by Google

strengthen the hands of the Government in its passage through the House of Commons.

Dr. PYE-SMITH accordingly moved a resolution in this sense, remarking that the Bill fulfilled the real object in view—namely, the formation of a great teaching university in London, and that it had received the approval of all the other bodies concerned. In urging the Government to pass the Bill the College would be acting in harmony with its previous action on the subject.

Dr. ALLCHIN, in seconding the resolution, pointed out in what particulars the measure differed from that of last year, and he did not consider that the changes were such as to affect the position of the Royal Colleges and the medical schools.

Dr. PAYNE thought that the position assigned to the medical schools was less satisfactory than in the previous Bill, since they would now come in as teachers and not as corporate institutions.

Dr. SANSOM expressed his warm approval of the measure, which he considered to be a fair compromise that would work well.

Sir W. PRIESTLEY gladly supported the resolution, but feared that the Government would have to abandon the measure should the threatened opposition be persisted in.

Dr. ISAMBARD OWEN deprecated the passing of a resolution without due consideration of the scheme.

Dr. NORMAN MOORE, however, said that in passing such a resolution the College would be acting consistently with its previous action. The resolution was then put and carried almost unanimously.

On the motion of the Registrar it was resolved for the first time that certain by-laws relating to Licentiates be enacted, re-enacted, or repealed, to conform with the changes recently effected in the examinations of the Conjoint Board.

On the motion of the Senior Censor, seconded by Dr. STEPHEN MACKENZIE, the following report of the Council was adopted:—

"The Council of the Royal College of Physicians, having considered with great care the memorial submitted to the College by the Hospital Reform Association, is of opinion that it is impossible for the College to make, in the words of the memorial, 'searching investigation into the present system of dispensing out-of-door medical relief at the hospitals, infirmaries, and dispensaries, not only in the metropolis, but in all the large provincial towns.'"

On the motion of the Senior Censor, seconded by Dr. ORD, it was unanimously resolved to adopt the recommendation of the Council to award the Moxon Medal to Sir Samuel Wilks, Bart., President of the College, "as having especially distinguished himself by observation and research in clinical medicine."

On the motion of Dr. PAYNE, seconded by Dr. ALLCHIN, it was unanimously resolved to adopt the recommendation of the Council to award the Baly medal to Professor Schäfer of University College, London, "as having especially distinguished himself in the science of physiology."

Reports were received from (*a*) the representative of the College in the General Medical Council, (*b*) the Finance Committee, (*c*) the Committee of Management, and (*d*) the Laboratories' Committee. In addition to their usual quarterly report on the work in progress at the laboratories this committee presented a special report upon the subject of standardising antitoxin, and recommending that the director should be authorised by the Royal Colleges to issue official certificates after testing the quality of samples of antitoxin submitted to him for this purpose. Some discussion ensued, shared in by Dr. PAVY, Dr. PYE-SMITH, Dr. KANTHACK, Dr. S. MARTIN, Dr. POORE, and Dr. HERON, and the recommendation was adopted.

Reports were also received from the Library Committee, the Curators of the Museum, and the Examiners for the Licence.

A list of books presented to the Library during the past quarter was handed in, and the thanks of the College voted to the donors. The thanks of the College were also given to Lady Russell Reynolds for the gift of two handsomely bound copies of Sir J. Russell Reynolds's "Addresses," to Sir Richard Quain for the gift of a photogravure portrait of himself, and to Dr. O'Neill, of Lincoln, for some valuable Roman remains found in that city.

The followiog is a list of the Censors and other officers elected for the ensuing year:—Censors: Dr. Samuel Jones Gee, Dr. Henry Charlton Bastian, Dr. Joseph Frank Payne, and Dr. William Miller Ord. Treasurer: Sir Dyce Duckworth. Emeritus Registrar: Sir Henry Pitman. Registrar: Dr. Edward Liveing. Harveian Librarian: Dr. William Munk. Elected Members of the Library Committee: Dr. Samuel Jones Gee, Dr. Philip Henry Pye-Smith, Dr. George Vivian Poore, and Dr. William Henry Allchin. Curators of the Museum: Dr. William Howship Dickinson, Dr. Henry Charlton Bastian, Dr. William Cayley, and Dr. Norman Moore. Finance Committee: Dr. Alfred Baynard Duffin, Dr. George Vivian Poore, and Dr. John Mitchell Bruce. Examiners: Chemistry and Chemical Physics: Mr. William Ramsay, F.R.S., Mr. Richard Tayler Plimpton, Ph.D., Mr. John Millar Thomson, F.R.S., Mr. Percy Faraday Frankland, Ph.D., F.R.S., and Mr. Frederick Daniel Chattaway, Ph.D., D.Sc. Materia Medica and Pharmacy: Dr. Francis Warner, Dr. William Carter, Dr. Nestor Isidore Charles Tirard, Dr. Sidney Philip Phillips, and Dr. James Calvert. Elementary Physiology: Dr. Henry Lewis Jones. Physiology: Dr. Vincent Dormer Harris, Dr. William Dobinson Halliburton, and Dr. John Wychenford Washbourn. Anatomy: Mr. George Robertson Turner and Mr. George Dancer Thane. Medical Anatomy and Principles and Practice of Medicine: Dr. William Cayley, Dr. Thomas Henry Green, Dr. Thomas Lauder Brunton, Dr. Isaac Burney Yeo, Dr. Arthur Ernest Sansom, Dr. Horatio Bryan Donkin, Dr. Thomas Barlow, Dr. William Ewart, Dr. David Bridge Lees, and Dr. Julius Dreschfeld. Midwifery and Diseases Peculiar to Women: Dr. John Baptiste Potter, Dr. Charles James Cullingworth, Dr. Peter Horrocks, Dr. John Phillips, and Dr. Robert Boxall. Surgical Anatomy and Principles and Practice of Surgery: Mr. John Langton and Mr. John Neville Colley Davies-Colley. Public Health: Part I., Dr. Thomas Stevenson; Part II., Dr. William Pasteur. Examiners for the Murchison Scholarship: Dr. Thomas Whipham and Dr. William Henry Allchin.

QUARTERLY REPORT OF THE RED CROSS.

THIS report has just missed being a very interesting document. The three months it covers include the Græco-Turkish war, in which both belligerents enjoyed the services of an ambulance furnished by Germany, an ambulance furnished by Russia (four ambulances, that is to say), and the Greeks alone had a Danish ambulance all to themselves, besides receiving generous gifts in kind from Rome, Budapest, Lisbon, Geneva, and other sympathising centres—all this, moreover (we are still speaking of the Greeks), in addition to a large outflow of compatriot charity. As for the Turks, their "Red Crescent Society," having its headquarters at Constantinople, gave them no assistance for the reasons that the outbreak of hostilities took it by surprise, that at the same moment it lost its president by death, and that the surviving members of its committee were not in a position to take the field. It did nothing, in fact, as long as the struggle lasted, and intervened only when the armistice was agreed to on May 27th, when it took part in the work of embarking and convoying the wounded by sea. The interest of Red Cross activity centres, accordingly, in the German, Russian, and Danish ambulances, but, unfortunately, none of them had prepared their reports when the "Chronique Trimestrielle de la Croix-Rouge," now before us, was in course of publication, so, as we have hinted, this document is unable to satisfy the curiosity of an eager world. Not that it is devoid of an interest of its own. The International Committee, which has its headquarters at Geneva—whose action, we need hardly say, is quite independent of the national committees (German, Russian, Danish)—performed a duty as salutary as it was unique, the duty, to wit, at the first warlike rumour, of ascertaining from the belligerents their probable clinical and sanitary wants with a view to obtaining from the neutral societies of the Red Cross such assistance as might be required. Having obtained the requisite information, the International Committee then addressed the neutral societies *en masse*, with the response already known, while it further declared to the belligerents that it was ready to organise in a suitable locality a central dépôt for the receipt, the custody, and the distribution of the offerings (medical, pharmaceutical, alimentary, and sumptuary) contributed by sympathising outsiders. This undertaking on the part of the International Committee, however, failed of effect, like many other equally well-inspired proposals in that unfortunate war, and it had

Digitized by Google

no opportunity of repeating in 1897 the admirable service it vouchsafed to the belligerents in the campaigns of 1870, 1877, and 1885. Another point in which the usefulness of the International Committee made itself felt was its willingness to act as intermediary between the belligerents, accusing each other reciprocally of non-observance of the articles of the Geneva Convention. In so acting the International Committee does not, of course, arrogate to itself the power of returning a verdict; it simply collects from the allegations of the disputant parties the materials on which the civilised world can pronounce an opinion on the conduct of either, so as to withhold from the offender that moral support which is year by year counting for more in the comity of nations. For instance, a protest was lodged by the Greeks against the Turks setting forth that the latter shelled the hospital at Arta. This the Turks denied, and the "Bulletin" of the International Committee became the medium of the representations *pro* and *contra*, providing the world at first hand with the facts of the case and enabling it to judge accordingly. From this *rôle*, rather thrust upon it than assumed, the International Committee is in a fair way of becoming a "Bureau de Consultation," if not a court of appeal, contributing thus to familiarise the world with that method of arbitration to which Christendom so fondly looks for the non-military settlement of difficulties. Indeed, the questions that from time to time come before it are such as to form a preparatory discipline for the "arbitration school." For example, "What use can a civil ambulance, organised by a neutral power and placed at the service of a belligerent, make of its own national flag?" Even more important is another question of the kind: "Has the Red Cross Society of a belligerent power, or the belligerent himself, the right to refuse the coöperation of an ambulance organised by the Red Cross of a neutral State?" Once more: "Is it lawful for a society of assistance to the wounded, recognised by the International Committee, to make use of another emblem than a red cross on a white ground—for example, a red crescent?" These are difficult questions, pressing for solution, and the facilities offered in this direction by the International Committee, with its experience of similar problems, cannot but be put in evidence at the Sixth International Congress of Red Cross Societies throughout the World which will meet on Sept. 20th at Vienna.

METROPOLITAN ASYLUMS BOARD STATISTICS.

I.—INFECTIOUS DISEASES.

THE Statistical Committee of the Metropolitan Asylums Board have just issued their eleventh annual report. The work of this Board and its value from a public health point of view increases from year to year, and the statistics contained in the report just issued show the same excellence of arrangement and method which has been conspicuous in its predecessors. During the year 1896 no fewer than 22 463 cases were received into the Board's hospitals for infectious diseases—a number considerably larger than that recorded in any year since 1871, when these hospitals were first opened. The nearest approach to this number occurred in 1893, when 21,050 cases were admitted, including 2376 small-pox patients. The main value of these isolation hospitals, from a sanitary point of view, arises from the possibility they provide for turning the notification of infectious diseases to practical account. The report just issued gives some valuable and interesting figures bearing on the connexion between the notification and isolation of infectious diseases in London in recent years. The year 1890 was the first in which compulsory notification was in force in London, and the proportion of admissions to the Board's hospitals to the total number of legally admissible cases was in that year 33 6 per cent. In the five following years the percentage of admissions to admissible cases rose, with some fluctuations, to 52·2 in 1894 and 50·3 in 1895. During last year 42 876 admissible cases were notified, of which 22 463, or 52·4 per cent., were actually received into the Board's hospitals. It is interesting to note that the proportion of admitted to admissible cases of the several diseases varied very widely; the proportion was 82 per cent. of small-pox cases, 63 per cent. of scarlet fever cases, 39 per cent. of cases of diphtheria and membranous croup, 27 per cent. of enteric fever cases, and 33 per cent. of typhus fever cases. It should be remembered, however, that the numbers of notified cases of these different diseases are probably of varying degrees of accuracy, which would affect to some extent the above-quoted percentages. It is, moreover, pointed out in the report that the proportion of admitted to admissible cases is at times considerably affected by the amount of hospital accommodation available. For instance, throughout last year the admitted cases of scarlet fever averaged 63 per cent. of the notified cases of that disease. It appears, however, that in the first five months of the year, in which the managers were able to accommodate all applicants, more than 70 per cent. of the notified cases were admitted, whereas later in the year, when the hospital accommodation fell short, the proportion of admitted to notified cases gradually declined to 57 per cent. in October, when the pressure for admission was greatest. This evidence of the need for increased hospital accommodation will probably not be lost sight of by the managers and by the ratepayers, on whom the heavy cost of this hospital accommodation falls. The report tells us that the completion of the works now in hand will place the managers in possession of nearly 6000 beds for infectious diseases other than small-pox.

During 1896 the number of patients admitted into the ten fever hospitals in use by the Board was 22,273, as compared with 16,847 in 1895, 16,667 in 1894, 18,674 in 1893, and 16,276 in 1892. Between 1891 and 1887 the numbers ranged between 5152 and 8334, and prior to 1887 the highest number in any year was 2867 in 1882. These figures show the remarkable extension of the work entrusted to the Metropolitan Asylums Board since the notification of infectious diseases became compulsory in London in 1890.

The cases of scarlet fever admitted to these hospitals last year were 15,982, and considerably exceeded the admissions in any previous year. The nearest approach to this number occurred in 1893, when 14,548 cases were admitted. The number of deaths from this disease in the Metropolitan Asylum Hospitals during the year was 666, equal to a proportional case mortality of 4·3 per cent., showing a further decline from the rates in the four preceding years, which had steadily decreased from 7·3 to 5·5 per cent. The marked and steady decline of the proportional case mortality of scarlet fever cases in the board's hospitals calls for further notice. In the ten years 1871–80 the case mortality was equal to 12·1 per cent., in 1881–90 it fell to 10·1 per cent., and in the six years 1891–96 it averaged only 6·0 per cent. It would be interesting to know what proportion of this decrease of mortality is due to modification of the type of the disease, how much to the treatment in the hospitals of an increased proportion of mild cases, and how much to more successful hospital treatment of the cases admitted. The report contains a valuable table showing the relation of age and sex to scarlet fever mortality, based upon 66,492 cases treated in these hospitals during the five years 1892–96. The most noticeable feature in these statistics is the fact that the mortality decreases with the age of the patient from 27 per cent. in the first year of life to 1·2 per cent. in the age-period 25–30; the mean percentage of case-mortality is 13·3 under five years of age, and averages 2·5 above the age of five years.

Cases of diphtheria were first treated in the Board's hospitals in 1888, when 99 were admitted. The number of cases admitted has steadily increased in each succeeding year, and rose to 4508 in 1896, which were equal to 39 per cent. of the cases notified. The deaths from this disease in the hospitals during the year were 948 and were equal to a case mortality of 21·2 per cent., showing a further decline of 1·7 per cent. from the percentage in the preceding year, when the antitoxin treatment was first generally adopted in these hospitals. It should be noted, however, that during the seven years 1888–94, prior to the trial of antitoxin, the case mortality of diphtheria in these hospitals steadily declined from 59·4 per cent. in 1888 to 29·3 in 1894. The percentages in 1895 and 1896, when the antitoxin treatment became general, further fell to 22·9 and 21·2. The report now under notice contains full and elaborate statistics bearing upon the result of the antitoxin treatment of diphtheria in these hospitals upon the case mortality, which call for careful consideration and separate notice. It may be noted that whereas 71 per cent. of the deaths from scarlet fever in London last year were recorded in the Board's hospitals, only 35 per cent. of the total deaths from diphtheria were recorded therein. It is,

Digitized by Google

however, satisfactory to find that the proportion of diphtheria cases in London isolated and treated in hospital has constantly increased in recent years. If, moreover, it be safe to assume that the number of notified cases of diphtheria in London approximates closely to the actual number of occurring cases, it would appear that the case mortality last year outside the Board's hospitals did not materially differ from the case mortality in those hospitals.

During 1896 the number of cases of enteric fever treated in the Board's hospitals was 600, and fewer by 61 than the number in the preceding year. The deaths from this disease during the year were 96, showing a case mortality of 15·8 per cent, against 20·5, 18·1, and 18·2 in the three preceding years. Case mortality from enteric fever in these hospitals has declined from 19·5 in the ten years 1871-80 to 16·4 in the ten years 1887-96, but this decline is small compared with the decrease in the case mortality of scarlet fever and diphtheria. The number of cases of enteric fever treated in these hospitals last year was equal to 27·0 per cent. of the notified cases, or if the cases handed over for treatment by the managers to the general hospitals be included the proportion is raised to 30·0 per cent. The 96 deaths from this disease in the Board's hospitals were equal to but 16·2 per cent. of the total deaths assigned to this cause during the year in London. The age incidence of enteric fever shows a marked contrast to that of scarlet fever and diphtheria. The number of deaths referred to enteric fever under the age of five years is small, and their case-mortality (based upon 10,484 cases at all ages in the Board's hospitals in the years 1871–96) is 13·2 per cent., but at subsequent age-periods the mortality increases steadily and constantly from 8·9 per cent. at the ages of from five to ten years, to 35·4 per cent. above the age of fifty years.

Only nine cases of typhus fever were admitted to these hospitals in 1896, resulting in two deaths. Of the 97 cases admitted in the nine years 1888–96, 18 proved fatal, showing a case mortality of 18·6 per cent., while the mean mortality during the whole period 1871–96 averaged 20·7 per cent. It appears, therefore, that the case mortality of typhus fever in hospital, as of the other infectious diseases, has declined in recent years.

Not more than 190 cases of small-pox were admitted to the Board's hospitals during last year, of which only 9 proved fatal, equal to a case mortality of but 4·7 per cent. The small-pox cases admitted in the three preceding years were 2376, 1117, and 941 respectively. It is worthy of note that these 9 fatal cases of small-pox were the only deaths from small-pox recorded in London during the whole year.

Before concluding this notice of the Metropolitan Asylums Board's statistics, so far as they relate to infectious diseases, it may be well to refer to some interesting figures given in the report relating to illness of members of the staff in the fever and small-pox hospitals. During last year there were 3542 persons employed at the fever hospitals, of whom 176, or 5·6 per cent., were attacked by fever or diphtheria, and 3 died; while of the 250 persons employed on the small-pox hospital ships, not one suffered from small-pox. The managers state that the experience of each succeeding year only confirms them in their belief that nurses and other members of a hospital staff may be brought with almost absolute impunity into contact with small-pox provided they are protected by efficient vaccination.

We must postpone to another occasion a notice of the valuable statistics relating to the more than 6000 imbecile patients under treatment in the asylums under the management of the Metropolitan Asylums Board.

THE HEALTH OF THE TROOPS IN INDIA.

A PARLIAMENTARY paper has been published, as we briefly announced last week, setting forth some "Further Correspondence regarding the Measures to be Adopted for Checking the Spread of Venereal Disease among the British Troops in India." As the subject is one of much interest and importance we may give a brief analysis of the contents of this Parliamentary paper, with such comments as occur to us. The military letter from the Government of India states that after having fully considered the despatch of the Secretary of State for India, with which our readers are already acquainted, together with the report of the Earl of Onslow's Committee, the memorandum of the Army Sanitary Commission dealing generally with the measures by which it is considered possible to restrict the spread of venereal disease among soldiers in India, and the representations of the Royal College of Physicians of London and the Royal College of Surgeons of England, they have drawn up and submitted the accompanying draft rules proposed to be issued under the Cantonments Act of 1889. These rules, amending and enlarging that Act, are framed on the lines of, and in accordance with, the principles embodied in the Secretary of State's despatch. Although they are stated to be drafted with the least degree of stringency necessary to enable cantonment authorities to deal with the evils against which they have to contend, it is considered that the repeal of Act V. of 1895 is necessary in order to protect medical and other officers in the performance of duties which the new rules will impose upon them. The Act of 1895 prohibiting examinations and removing the then existing safeguards against the spread of venereal disease was, it will be remembered, the result of orders from this country. Exception is taken to the suggestion of the Army Sanitary Commission with regard to the employment of female hospital assistants for the examination of diseased women, on the ground that it is, under the circumstances, an unnecessary, and in many respects an unsuitable, provision. The difficulties in the way of giving effect to this suggestion of the Army Sanitary Commission and the practical objections to it are well and very pertinently indicated. The desirability of raising the moral and physical condition of the army and of warning young soldiers on their arrival in India of the dangers to which they are exposed are pointedly recognised, and the steps which have already been, and will hereafter be, taken in this direction are adverted to. With regard to the inspection of soldiers, the imposition of penal stoppages for admission to hospital, and the punishment of soldiers concealing venereal disease, the Commander-in-Chief makes some propositions which are embodied in a letter from the Adjutant-General in India accompanying the despatch. Speaking generally, we consider that the proposals emanating from the Government of India are wise, judicious, extremely moderate, and under the circumstances absolutely necessary; and we are glad to notice that the Secretary of State has telegraphed his authority to the Viceroy to proceed in the manner proposed. We feel it right, however, to advert to certain points in regard to which we either do not agree or are not without misgiving. In the first place, while admitting that there may be some force in the objections raised in India against the employment of female hospital assistants under the direction of medical officers in the examination and treatment of women, we nevertheless concur with the dissent expressed by Lord George Hamilton in his despatch, for we regard it, on the contrary, as a necessary and suitable provision. The employment of females for this purpose to a very large extent deprives of any force the objection which is so strongly urged by the opponents to all legislative measures. Notwithstanding the difficulties that may exist in carrying it out at present on any extensive scale it should be given a trial wherever practicable. In the next place, as regards penal stoppages being imposed upon a soldier for every day spent in hospital on account of venereal disease, and a change being introduced into the Army Act and regulations so that this may be made universally applicable to the British Army, we entertain grave doubts. It may be fairly urged, of course, that it is logically and morally wrong to apply the same rule to the soldier undergoing treatment for a self-inflicted disease or a complaint caused by his own misconduct and to the soldier suffering from a disease or disability which has been contracted in the execution of his duty and over the origin of which he had no control. But in that case whatever loss of pay is forfeited should not go to the State, but to the benefit of the corps to which the soldier belongs and to those who had to do his duty whilst in hospital. We think it probable that soldiers would recognise the justice of the view that a difference should be made between the daily pay of a soldier in hospital for an attack of pneumonia, rheumatic fever, typhoid fever, or ague, and that of one suffering from venereal disease; but the latter should, even then, not forfeit all his daily pay, and whatever loss he incurred in this respect should not be for the benefit of

Digitized by Google

the State. The danger of imposing any system of fines or penal stoppages is lest it should lead to concealment of disease. Nor should the possible effect on recruiting of any unpopular measure be lost sight of. The subject will, no doubt, be carefully considered, however, by the Secretary of State for War.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on July 29th, the President, Sir WILLIAM MACCORMAC, Bart., being in the chair.

On the recommendation of the Library Committee, Mr. Victor Gustave Plarr, B.A. Oxon., and late librarian at King's College, London, was appointed librarian. A vote of thanks was given to Mr. C. R. Hewitt, assistant in the library, together with an honorarium, in recognition of his valuable services in the library since the death of Mr. James B. Bailey; Mr. Hewitt's salary was also increased.

It was resolved that the museum and library should be closed from Aug. 28th to Oct. 1st.

The following recommendations of the Committee of Management of the Conjoint Examining Board were adopted:—

1. That the following institutions be added to the list of recognised places of instruction in chemistry, physics, practical chemistry, and biology:—*(a)* Battersea Polytechnic Institute. *(b)* Cheltenham College (without biology). *(c)* Middlesbrough High School (without biology). *(d)* Northern Polytechnic Institute.
2. That the following hospitals be added to the list of fever hospitals recognised by the Board:—*(a)* Bristol Corporation Fever Hospital. *(b)* Manchester Corporation Fever Hospital.
3. That the following asylums be added to the list of lunatic asylums recognised by the Board:—*(a)* City and County Asylum, Fishponds, Bristol. *(b)* Manchester Royal Asylum, Cheadle.
4. That the Victoria Hospital for Children, Chelsea, be recognised as a place of study during the fifth year of the curriculum.
5. That the Royal Westminster Ophthalmic Hospital be added to the list of ophthalmic hospitals recognised by the Board.

Mr. J. N. C. Davies-Colley and Mr. C. H. Golding-Bird were elected members of the Court of Examiners.

Sir William MacCormac was elected a member of the Committee of Management in the vacancy occasioned by the resignation of Mr. Christopher Heath.

A letter was read from Mr. G. F. Oldham communicating the following resolution adopted at a meeting of members of the medical profession in Norwich, held on the 17th inst., viz.:—

"That this meeting, while acknowledging with thanks the reply of the Royal College of Surgeons to the Norwich memorial, desires to express the opinion that steps should be taken so to amend Section XVI. of the by-laws as to enable the Council to prevent its Fellows, Members, or Licentiates accepting positions derogatory to the honour and best interests of the profession."

In reply to a letter from the Rev. J. J. H. S. Pennington stating that he still required £1100 for the completion of the St. Clement Danes Parish House and asking for a further contribution, the Council voted 10 guineas.

The following resolution, moved by Mr. J. Tweedy, was carried: "That the printed copies of the minutes of the Council be considered the property of the College, and that regulations be framed with a view to preventing unauthorised persons from obtaining them."

A letter was read from Lord Salisbury announcing that an International Conference on Leprosy would shortly be held in Berlin.

A recommendation was received from the Laboratories Committee that the director should be authorised to issue an official certificate of the strength of diphtheria antitoxins tested in the laboratories.

CHILDREN'S CONVALESCENT HOME, WEST KIRBY.—At the instigation of Mr. W. Adamson, president of the Liverpool Royal Southern Hospital, a few local gentlemen have subscribed the sum of £600 for the purpose of endowing a free bed at the Convalescent Home, West Kirby, for the use of patients from the Royal Southern Hospital, which, by Royal permission, has been called "Queen Victoria Cot." As the Liverpool Royal Infirmary is already in the possession of a cot endowed by the liberality of Mr. A. K. Cannington, it is hoped by the committee that similar endowments will be made by the benevolent on behalf of the other city hospitals, especially the Children's Infirmary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool Port District.—The formation of the Port Sanitary District of Manchester, owing to the existence of the Manchester Ship Canal, has thrown upon the sanitary authority of that newly-created district the responsibility of dealing with ship-borne infection on Manchester-bound vessels, and has dispensed with the necessity for the proposed arrangement with the Liverpool Port Sanitary Authority for dealing with certain infectious diseases on board vessels passing through the waters of the Liverpool Port Sanitary Authority. There were no less than 3516 vessels examined by the Liverpool Port Sanitary inspectors during 1896, and of this number 1996 had some sanitary defect or other. Seventy-three cases of infectious disease were landed from shipping during the year, and among cases classed as non-infectious we notice fifteen cases of beri-beri. A marked diminution in the number of emigrants leaving Liverpool took place during 1896, the numbers amounting to only 98,279, as against 117,196 in 1895. Dr. E. W. Hope thinks it probable that a large number of emigrants pass now direct from the Continent instead of *viâ* Liverpool as formerly. Among the English emigrants who left Liverpool during 1896, 31,571 went to the United States and 12,768 to Canada.

Birmingham Urban District.—For the first time in the history of the city of Birmingham the population has been estimated at over half a million, while the average number of persons per acre has reached 39·5, as against 36·4 in 1887. Dr. Alfred Hill does not speak enthusiastically as to the mortality statistics for the past year, the general death-rate (20·4 per 1000) being higher than in recent years, and the position of Birmingham amongst the other large towns being less creditable than heretofore. As Dr. Hill somewhat pathetically remarks: "It is anything but reassuring to find that the greater part of the increase in last year's mortality was caused by the serious prevalence of zymotic diseases, all of which (except small-pox) were much more fatal than in the five previous years." When the death-rate of the several wards of the city is worked out it is found that there is much inequality, the rate for St. Mary's Ward being 28·9, that for Balsall Heath 15·4, or, taking the nine worst wards, it is found that they yield a death-rate of 24·5, as against one of 17·7 in the better wards. A further analysis shows that the more prominent causes of death were higher in the nine worst wards (save in respect of cancer and diphtheria), while diarrhœa and enteric fever were nearly twice as common in the bad wards as in the good ones. Dr. Hill, in discussing the causes of these high mortality rates, expresses the opinion that the want of ventilation is the most important feature with which the sanitary authority has to deal, and he provides a table which appears to demonstrate very clearly the excellent effects of improved houses and of better ventilation. The figures are so remarkable that we give them here:—

—	Death-rate, 1873–1875.	Death-rate, 1879–1881.
Lower Priory	62·5	21·9
Rope-walk	42·0	24·9
Bailey-street	97·0	25·6
Potter-street	44·0	28·8
Russell-street	55·0	19·1
Princip-street	46·0	13·2
Aston-road	40·0	19·3
Tanter-street	47·0	22·0

There were 14 cases of small-pox in Birmingham during 1896, the three first cases having been introduced from Gloucester, facts which show, as Dr. Hill observes, the folly of allowing communities to please themselves as to whether they shall enforce the vaccination laws or not. Measles caused 310 deaths in Birmingham in 1896, and Dr. Hill remarks that if any notable reduction is to be effected in the death-rate from this disease, much more definite action will have to be

Digitized by Google

taken than is the case at present. He considers notification to be as yet impracticable in Birmingham, and he suggests that the sanitary officers should obtain from the School Board officials the names of all children who are absent owing to measles; and that printed instructions should be forwarded to the invaded houses. Dr. Hill proposes that exactly the same lines of action should be taken in the matter of whooping-cough. The necessity for the control of these two latter diseases is shown by the fact that during the decade 1886–95 the average annual number of deaths from measles was 237, and from whooping-cough 257, while scarlet fever and diphtheria claimed but 94 and 69 respectively. The fall in the fatality rate of scarlet fever in Birmingham during the last two decades is very clearly shown in the following table in the report:—

—	Cases.	Deaths.	Case mortality.
1875–78	538	78	14·6 per cent.
1879–83	1948	207	10·6 ,, ,,
1884–90	6201	383	6·2 ,, ,,
1891–93	10,661	473	4·4 ,, ,,

And it may be noted that the reduced fatality-rates have gone side by side with the increased hospital isolation of the disease. The behaviour of diphtheria in Birmingham is full of interest, and there seems to be no adequate explanation of the increased incidence during the last two years. In 1873 the death-rate from this disease was 0·31 per 1000, and this rate gradually diminished until in 1893 it reached 0·09 per 1000. Towards the end of 1894 a rise commenced which reached in 1896 no less than 0·48 per 1000. Dr. Hill can furnish no sufficient explanation of this rise, and it seems clear from the distribution of the disease that it is not dependent upon grave insanitary conditions. The rise is a most puzzling one and well merits the close study which it will doubtless receive at the hands of Dr. Hill.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6662 births and 4827 deaths were registered during the week ending July 31st The annual rate of mortality in these towns, which had increased from 14·7 to 19·3 per 1000 in the four preceding weeks, further rose last week to 22·9. In London the rate was 23·6 per 1000, while it averaged 22·4 in the thirty-two provincial towns. The lowest rates in these towns were 9·9 in Croydon, 10·3 in Huddersfield and in Halifax, 12·2 in Oldham, and 13·5 in Cardiff; the highest rates were 28·0 in Portsmouth, 28·7 in Wolverhampton, 31·7 in Preston, 32·0 in Sheffield, and 32·6 in Liverpool. The 4827 deaths included 1337 which were referred to the principal zymotic diseases, against 572 and 904 in the two preceding weeks; of these, 994 resulted from diarrhœa, 143 from measles, 87 from whooping-cough, 54 from diphtheria, 37 from scarlet fever, 21 from "fever" (principally enteric), and 1 from small-pox. No death from any of these diseases was recorded last week in Huddersfield; in the other towns they caused the lowest death-rates in Cardiff, Halifax, and Derby; and the highest rates in Sheffield, Wolverhampton, Liverpool, Preston, and Portsmouth. The greatest mortality from measles occurred in Manchester, Salford, Burnley, and Preston; from whooping-cough in West Ham, Plymouth, Wolverhampton, Burnley, and Gateshead; and from diarrhœa in Portsmouth, Wolverhampton, Nottingham, Birkenhead, Liverpool, and Sheffield. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 54 deaths from diphtheria included 41 in London, 2 in West Ham, and 2 in Liverpool. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns, and there was one small-pox patient under treatment during last week in the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had increased from 2380 to 2976 at the end of the thirteen preceding weeks, had further risen to 3106 on Saturday last, July 31st; 360 new cases were admitted during the week, against 349, 381, and 396 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 138 and 158 in the two preceding weeks, declined again to 146 last week, and were 30 below the corrected average. The causes of 60, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Leeds, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Bristol, Birmingham, Liverpool, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 17·7 to 19·5 per 1000, declined again to 18·2 during the week ending July 31st, and was 4·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·5 in Aberdeen and 14·7 in Paisley to 20·7 in Dundee and 21·4 in Leith. The 542 deaths in these towns included 51 from diarrhœa, 22 from whooping-cough, 5 from scarlet fever, 5 from measles, 3 from diphtheria, and 2 from "fever." In all, 89 deaths resulted from these principal zymotic diseases, against 80 and 100 in the two preceding weeks. These 89 deaths were equal to an annual rate of 3·0 per 1000, which was 3·5 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had increased from 20 to 35 in the four preceding weeks, further rose to 51 last week, of which 29 occurred in Glasgow and 6 in Greenock. The 22 deaths referred to whooping-cough showed a decline of 15 from the number recorded in the preceding week, and included 14 in Glasgow and 4 in Leith. The 5 fatal cases of scarlet fever corresponded with the number in the preceding week, and included 4 in Edinburgh. The deaths from measles, which had been 12 and 15 in the two preceding weeks, declined again to 5 last week, of which 4 occurred in Leith. The 3 fatal cases of diphtheria included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 68 and 87 in the two preceding weeks, declined to 66 last week, but slightly exceeded the number in the corresponding period of last year. The causes of 30, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·2 and 23·3 per 1000 in the two preceding weeks, further declined to 22·8 during the week ending July 31st. During the past four weeks of the current quarter the death-rate in the city has averaged 23·0 per 1000, the rate during the same period being 18·8 in London and 19·6 in Edinburgh. The 153 deaths registered in Dublin during the week under notice showed a decline of 3 from the number in the preceding week, and included 16 which were referred to the principal zymotic diseases, against 11 and 20 in the two preceding weeks; of these, 8 resulted from diarrhœa, 3 from diphtheria, 1 from scarlet fever, 1 from whooping-cough, and 1 from "fever." These 14 deaths were equal to an annual rate of 2·1 per 1000. the zymotic death-rate during the same period being 6·9 in London and 1·6 in Edinburgh. The fatal cases of diarrhœa, which had been 2 and 7 in the two preceding weeks, further rose to 8 last week. The 3 deaths referred to diphtheria corresponded with the number registered in the preceding week, while the mortality from scarlet fever and from whooping-cough showed a decline. The 153 deaths in Dublin last week included 42 of infants under one year of age, and 31 of persons aged upwards of sixty years; the deaths of infants showed a further increase upon those recorded in recent weeks, while those of elderly persons showed a decline. Seven inquest cases and 4 deaths from violence were registered; and 49, or nearly a third, of the deaths occurred in public institutions. The causes of 12, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR MICHAEL F. MACNAMARA, F.R.C.S.Irel., retires from the service, receiving a gratuity. The undermentioned Surgeon-Lieutenants to be Surgeon-Captains:—Percy Evans, M.B., Arthur E. Milner, Claude K. Morgan, M.B, John P. Silver, M.B., Herbert W. Vaughan-Williams, M.B., John M. Buist, M.B, James Walker, M.B., Frank Dove, George St. Clair Thom, M.B., and Stephen W. Sweetnam.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain William Alfred Dingle, M.D., 2nd Tower Hamlets Royal Engineers (Volunteers), to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 1st Monmouthshire: Surgeon-Lieutenant W. E James to be Surgeon-Captain. *Rifle:* 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Major W. Stephenson to be Surgeon-Lieutenant-Colonel. 2nd Volunteer Battalion the Duke of Edinburgh's (Wiltshire Regiment): Surgeon-Lieutenant G. R. Swinhoe to be Surgeon-Captain.

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-fourth session of the Army Medical School, Netley, was brought to a close on July 30th, when the prizes were distributed and an address was given by Major-General Sir William F. Butler, K.C.B., Commanding the South-Eastern District. The following is a list of Surgeons on probation who were successful both at the London and Netley examination. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School, and the final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley.

ARMY MEDICAL SERVICE.

	Combined marks.		Combined marks.
†S. L. Cummins	4671	J. Poe	3942
J. McArdle	4455	H. L. W. Norrington ...	3928
‡C. H. Hopkins	4247	H. G. F. Stallard	3806
L. J. C. Hearn	4227	R. D. Jephson	3654
P. Mackessack	4172	J. Crean	3577
J. McD. McCarthy ...	4147	A. W. N. Bowen	3413
E. Brodribb	4085		

† Gained the de Chaumont Prize in Hygiene.
‡ Gained the second Montefiore Prize.

INDIAN MEDICAL SERVICE.

	Combined marks.		Combined marks.
*J. G. P. Murray	5644	A. Fenton	5093
†S. Anderson	5428	J. A. Dredge	5006
‡F. H. G. Hutchinson ...	5390	R. W. Knox	4885
§J. L. Majoribanks	5208		

* Gained the Herbert Prize of £20, the Martin Memorial Medal, and the Pathology Prize presented by Sir Joseph Fayrer, Bart., K.C.S.I.
† Gained the Maclean Prize for Clinical and Ward Work.
‡ Gained the Parkes' Memorial Medal.
§ Gained the first Montefiore Prize of 20 guineas and Bronze Medal.

Owing to the extraordinary pressure on our space by reason of the publication of our special Russian supplement we are compelled to hold over the report of the proceedings and Sir William F. Butler's address till our next issue.

THE TOCHI EXPEDITION.

The *Army and Navy Gazette* says: "The medical arrangements of the Tochi expedition are: Principal Medical Officer, Surgeon-Colonel Carew, D.S.O.; Argyll and Sutherland Highlanders, Surgeon-Captain Swan; Rifle Brigade, Surgeon-Major O'Donnell. No. 2 British Field Hospital: Surgeon-Majors Townsend and Skinner, and Surgeon-Captains Mansby and Johnson. Sections A and B, No. 3 British Field Hospital: Surgeon-Major Kelly and Surgeon-Captain McDowell; 14th Sikhs, Surgeon-Captain Irvine, I.M.S.; 25th Bengal Infantry, Surgeon-Captain Drake-Brockman; 33rd Bengal Infantry, Surgeon-Captain Evans; 1st Sikh Infantry, Surgeon-Captain Seton; 1st Punjab Infantry, Surgeon-Captain Vizzard. No. 28 Native Field Hospital: Surgeon-Lieutenant Colonel Mawson, Surgeon-Major Briton, and Surgeon-Captains Gee and Mulvaney. No. 29 Native Field Hospital: Surgeon-Lieutenant-Colonel Simmonds, Surgeon-Captain McLeod, and Surgeon-Lieutenants Morgan and James. No. 38 Native Field Hospital: Surgeon-Major Hudson, Surgeon-Captain Elliott, and Surgeon-Lieutenants Scott Moncreiff and Morehead. Native General Hospital, Bannu: Surgeon-Major Mukerjee, Surgeon-Captain Rogers, and Surgeon-Lieutenant Dee."

THE RELIEF OF CHAKDARA.

The relief of Chakdara seems to have been effected by a well-designed plan executed with skill, and the enemy was completely surprised. The losses of the Chakdara garrison, and those of the force that advanced to its relief were relatively small. A large native force provided with scaling ladders, which were preparing to attack Chakdara, had to retire hastily. Malakand is reported to be quiet. Whether the tribesmen are determined on further resistance has yet to be seen, but it will be the object of the punitive British force to so completely dominate them as to put an end to their future mischief—not an easy task under the circumstances and the difficult conditions of the country. Meanwhile there will be a good deal of occupation for the medical officers in organising their hospitals, in attending to the sick and wounded, and arranging for their transport to the base.

Surgeon-Captain W. H. Horrocks, M.B., A.M.S., has been appointed Assistant Professor of Military Hygiene at the Army Medical School, Netley, vice Surgeon-Major Firth, F.R.C.S. Eng., whose period of service will expire on Sept. 1st.

Correspondence.

"Audi alteram partem."

AN INVITATION FROM HAMBURG.

To the Editors of THE LANCET.

SIRS,—On behalf of the Hamburg Committee in connexion with the Twelfth International Medical Congress I venture to express the hope that many of our English colleagues will pass through Hamburg going to Scandinavia on the way to Moscow.

In addition to the General Hospital (Neues Allgemeines Krankenhaus) Hamburg possesses various other hospitals, medical institutions, and places of interest, all of which we shall be most happy to show to our visitors.

I am, Sirs, yours faithfully,

Hamburg, July 31st. DR. KÜMMELL.

"HOSPITAL ABUSE."

To the Editors of THE LANCET.

SIRS,—I can understand that the self-sufficient gentleman who called upon some of us here respecting the subject of "Hospital Abuse" should have resented being told to mind his own business and allow us to mind ours; but it is inconceivable that THE LANCET, which owes something to its position as the leading English medical journal, should have allowed such a spiteful misrepresentation of the profession in this city as that which is published as the report of the "Special Commissioner" on Hospital Abuse in Birmingham to appear in its columns. It is a cowardly and cruel libel to say that the profession there is so saturated with the commercial spirit and so engrossed with making money that it cares nothing for these questions, and the Editors of THE LANCET must have been suffering from the effects of the dog-days when they allowed such a monstrous accusation to pass their censorship. What is the charge which this precious Commissioner makes? It is that Birmingham having taken the lead in the question of hospital reform, has not been able to attain to any practical result. But where has such a result been obtained under conditions anywhere comparable to ours? And are we to be fairly exposed to the taunt of being a money-grubbing, disorganised profession because difficulties which have been nowhere overcome have been to us so far insuperable, or because many of us think that if they are to be overcome it will be by tact, patience, and the growth of the conviction that the medical profession is only asking what is right and reasonable, or that this consummation will not be promoted by the interference of outsiders whose acquaintance with our local

Digitized by Google

conditions must be very imperfect? It is to be hoped that you will in future conduct your campaign without indulging your "Commissioner" in coarse abuse of the profession here or elsewhere.

I am, Sirs, yours truly,

R. SAUNDBY, M.D. Edin., F.R.C.P. Lond.

Birmingham, Aug. 1st, 1897.

THE CONGRESS IN MOSCOW: RUSSIAN PASSPORTS.

To the Editors of THE LANCET.

SIRS,—Will you allow me to correct one small mis-statement in your "hints" to intending visitors to Moscow, printed in THE LANCET of July 24th? You say: "If he [the traveller] is staying in a private house he must himself take his passport to the nearest police office." This is not quite the case. The traveller staying in a private house has practically no responsibility with regard to his passport. It is the duty of the *dvornik* or porter attached by law to every house to obtain the traveller's passport and take it to the police. It is also the *dvornik's* duty to obtain the necessary permission of the authorities to enable the traveller to leave the country. In both cases the traveller himself remains passive. If his passport is in order, that is to say, if it has been *visé* by a Russian consul in London or elsewhere, he has no further trouble; the system works automatically. May I also add to your first hint, that "a passport is absolutely necessary," that a passport itself is useless unless it has been *visé*, as just stated, at a Russian consulate.

I am, Sirs, yours faithfully,

St. Petersburg, July 17th (29th), 1897. FRANK G. CLEMOW.

CULLINGWORTH FUND.

To the Editors of THE LANCET.

SIRS,—Will you allow us to make a brief statement in your columns as to the Cullingworth Fund, which is now finally closed? It was hoped that we should be able to defer sending out the balance-sheet until the litigation had been brought to a conclusion, but Miss Beatty has applied for permission to appeal to the House of Lords *in formâ pauperis*, and though this application has been refused it is still open to her to proceed with the suit in the ordinary way. Under the circumstances we have thought it better to issue the balance-sheet without further delay. The amount subscribed is £972, a sum which will, it is hoped, fully cover Dr. Cullingworth's legal expenses. The incidental expenses would have been much greater had it not been for the generous coöperation of yourselves and the editor of the *British Medical Journal*, which we desire cordially to acknowledge.—We remain, Sirs, yours faithfully,

T. D. ACLAND, B. PITTS, } Hon. Secs.

TREASURER'S STATEMENT.

Receipts as per published lists	£872	0 0	Paid to Dr. Cullingworth	£959	14 6

July 30th, 1897. W. ROBERTS, Hon. Treasurer.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Antitetanus Serum as a Preventive.

AT the last meeting of the Academy of Medicine M. Nocard, continuing the subject introduced by him some eight days previously, brought forward evidence to prove that a small dose of antitetanus serum was enough to immunise a horse against a fatal dose of tetanus toxin. The use of antitetanus serum as a preventive has been in force for some years in veterinary practice in cases of wounds, castration, or other surgical procedures. To this end the Pasteur Institute has supplied 7000 doses of antitetanus serum, a dose being 10 c.c., a quantity which has sufficed to treat preventively 3100 animals in those parts of the country where tetanus is endemic. Among these there has been no death from tetanus. In the case of one horse injected five days after receiving a wound tetanus developed, but the attack was slight. During the same time that these animals were injected the same veterinary surgeon observed among animals not treated by injection 259 cases of tetanus. There would therefore seem to be no doubt of the utility of preventive injections of serum in veterinary practice.

The Surgical Treatment of Exophthalmic Goitre.

At the same meeting of the Academy two very important communications were made by the respective champions of the rival methods for the cure of exophthalmic goitre by operation. M. Jaboulay spoke in favour of resection of the cervical sympathetic nerve, while M. Doyen held out for the total extirpation of the thyroid body. M. Jaboulay related how the idea of the operation he favoured came to him some eighteen months ago. Having removed the whole thyroid body, including the median lobe, in a goitrous patient without any relief being experienced, he remembered that the two most prominent symptoms in exophthalmic goitre—namely, exophthalmos and cardiac palpitations—could also be produced by an acute excitation of the cervical sympathetic, so he made up his mind to try section of this nerve in a case of this particular disease. He had operated upon nine patients and had obtained in all a great amelioration of the symptoms, besides which the operation was simple and devoid of danger. His method had been followed by other operators in various parts of France, and the number of cases reported up to the present was fourteen.[1] On the other side M. Doyen brought forward two cases of exophthalmic goitre treated by ablation of the whole of the thyroid body. In these patients the operation was followed by the immediate and lasting disappearance of all the symptoms. Notwithstanding that the cure seemed complete, one patient, although deprived of a thyroid, was attacked by a fresh crisis of exophthalmos, dyspnœa, and cardiac palpitation, but this was owing to her undergoing an untimely course of thyroid treatment, and the symptoms wholly subsided on all treatment being stopped. M. Doyen therefore advised ablation of the thyroid, and considered section or resection of the cervical sympathetic as a merely indirect method of treatment.

A New Method of treating Adherent Ulcer of the Stomach.

Dr. Delageniere, of Mans, reported to the Academy that in a complicated case of gastric ulcer, where perforation had taken place and the organ was adherent to the diaphragm, he detached the adherent portion together with a part of the muscle to which it was adherent, inverted the affected parts into the cavity of the stomach together with the bit of muscle, to the end that they might be digested, and brought the edges of the fold together with sutures. The patient rapidly recovered, and up to the present remains well. Dr. Delageniere considers that this operation is indicated in all cases of gastric ulcer which have resisted ordinary treatment.

The Paris Milk-supply.

This very important question is at present the leading topic in Paris. Two absolutely different opinions are evident. On the one hand, all the medical men demand that every precaution to ensure a supply of pure milk should be taken, together with sterilisation and a rigorous inspection of cowsheds, dairies, &c. On the other hand, those interested in the trade complain of the severity of these measures. The syndicate of cow-keepers in Paris and the suburbs have set forth their ideas on the matter, the President stating that owing to the progress which had occurred during the last fifteen or twenty years the sheds in Paris where milch cows were kept were in far better condition than many farms in the country. The most remarkable improvements had been introduced into the Parisian cowsheds, and although this might be due to the severe regulations of the municipal laboratory, still it could not be denied that they were there. Under these conditions they considered that they should no longer be treated as suspected persons, and with regard to the laws concerning tuberculosis they passed a series of resolutions. 1. That the declaration which all cow-keepers have to sign whenever one of their stock falls ill should remain in force, but only when the animal shows definite signs of tuberculosis. 2. That a penalty should only be inflicted by the

[1] THE LANCET, July 10th, 1897, p. 120.

Digitized by Google

court when the accused has acted in bad faith. 3. That the penalties enacted by the law of 1881 should be reduced. Dr. Budin, the chief physician to the Maternity Hospital, in his report dealing with milk foods and feeding, proposes that no milk below a certain standard of richness in fat should be considered as milk from the hygienic point of view or be sold under that name. For sterilisation boiling and keeping hot for three-quarters of an hour in a water bath of boiling water is sufficient for milk to be consumed within twenty-four hours. It is not enough that there should be a supply of good raw milk or even of sterilised milk, but means must be taken to bring such supply within reach of the poor of Paris, who are generally unable to procure good milk. Sterilised milk, or in some cases sterilisers, should be distributed among the necessitous mothers of Paris who at present cannot bring up their infants at the breast. Those mothers who are in slightly better circumstances might be given tickets for either milk or a steriliser. Milk might be called in certain cases an indispensable drug, and the *bureaux de bienfaisance* ought to be able to prescribe it like other drugs.

(FROM OUR OWN CORRESPONDENT.)

The German Commission on Plague.

THE members of the German Commission on Plague have recently returned to Europe, with the exception of Professor Koch, who went direct from Bombay to the German colonies in East Africa. Some preliminary notices of the work of the Commission have again appeared in the official papers of the Government. The Commission states that the bacillus of plague very easily perishes outside the human body or that of animals. Cultures of the bacilli were destroyed by boiling and by corrosive sublimate at once, by mineral acids within five minutes, by carbolic acid within ten minutes, and by milk of lime within an hour. In ordinary town water the bacilli died within three days, being unable to live without atmospheric oxygen. Pigeons, fowls, geese, and pigs did not show any reaction after injections of cultures of the bacilli; sheep and goats were more sensitive to the infection; whilst horses, and especially cattle, were very liable to contract the disease. All the animals artificially infected eventually recovered. The greatest liability to the disease was presented by rats, which, it was found, carried the bacilli from house to house, and in this way were very dangerous to the population. Grey monkeys were also very liable to the disease, but brown monkeys were not quite so readily affected. Monkeys were therefore used for the study of artificial immunisation. It was proved by experiments that injections of Haffkine's serum produced immunity, especially cultures of high virulence which had been exposed to a temperature of 65° C. (149° F.) for an hour. The immunity appeared after a period of from five to seven days. Monkeys immunised in this way were immune against about two milligrammes of a culture of plague bacilli. The serum of Yersin was also tested by the Commission. An injection of 2 c.c. of this serum given to brown monkeys made them immune against 2 c.c. of plague culture, but it was found that 1 c.c. was not sufficient for the purpose. With grey monkeys, however, the serum was useless. The immunity of brown monkeys lasted only eight days. Strong serum had a remedial effect on these monkeys, but there was no evidence that the disease occurring in the human subject could be treated in this way. The report further states that Professor Koch, on May 18th, visited the Portuguese town of Damaon, where he observed that the natives who lived in houses had nearly all caught the disease, whereas those who camped out were comparatively seldom attacked. The effect of 1400 injections performed there after Haffkine's method was to produce marked immunisation; some of these patients fell ill, but only twenty of them died, and in most cases the symptoms were mild. Some members of the Commission visited the North-West Provinces for the purpose of investigating a disease called mahamari, which is apparently identical with the bubonic plague.

The late Professor Joseph Oertel.

Dr. Joseph Oertel, Professor of Laryngology at Munich University,[1] and one of the leading physicians of Germany, died in Munich on July 13th. He was born in Dillingen, Bavaria, in 1835, and after having finished his curriculum at the University of Munich he went to Vienna, where Professor Czermak had just begun to introduce the laryngoscope into medical practice. After his return to Munich he became *privat-docent*, and in 1876 Extraordinary Professor of Laryngology. His principal publication during this time was a treatise on Epidemic Diphtheria, being a part of the great "Handbuch der speciellen Pathologie" edited by Professor von Ziemssen. He was known to be a very clever laryngologist, but his reputation was limited to this branch of practice, and it was therefore somewhat of a surprise to the medical profession when he published in 1884 a work entitled "The General Treatment of the Disorders of the Circulation," the subject being one which had no connexion with the department of medicine he had hitherto cultivated. In this treatise, which subsequently became one of the standard works on medical treatment, he argued that in order to remove œdema and other symptoms of circulatory troubles water must be withheld as much as possible and the heart must be strengthened by exercises of some kind, especially by walking uphill. To this end he prescribed a special diet, the principal points of which were the general discouragement of drinking, especially during meals, and an absolute prohibition against taking soups and other food containing much water. He endeavoured to strengthen the heart by the "terrain cure," which is generally known by all medical men. He first introduced this system at Meran, a health resort in the Tyrol, where he induced the local authorities to set up round the town notices by which patients could find out how far they had come, and whether the road before them was level or steep. This system of "terrain cure" was subsequently introduced in many health resorts, especially in Southern Germany, and whoever has visited Baden-Baden, Wiesbaden, Kreuth, Aussee, &c, must have seen the coloured marks so essential for this plan of treatment. Professor Oertel's first trials of his new method were made on himself. A true Bavarian, he was not averse to the use of beer; he was also very round-shouldered, and soon after entering on practice he began to suffer from œdema and other symptoms of cardiac failure. He then resolved to live in the way above described, and satisfied himself as to the soundness of his method by means of chemical and physiological observations. It was in his own case so successful that, as he told me himself, although he had for several years been unable to walk more than a few hundred steps at a time, he ultimately became able to climb mountains like strong people. Professor Oertel had an extremely kind manner, and was much liked by the numerous patients who came from all parts of the world to consult him.

The International Medical Congress at Moscow.

A correspondent whose letter appeared in THE LANCET of July 17th (page 168) complained of the difficulties which attend the remitting of money to Russia. In Germany the matter was arranged by our national committee appointing one of its number as treasurer, who received the money from the German members and sent it in one sum to Russia. He issued provisional receipts, which were taken as legal documents by the Russian consuls for the purchase of passports. This arrangement, however, was only in force till July 20th, and members inscribed after this date had to apply directly to the Russian committee. It was said that the Russian committee would send the requisite vouchers immediately, but although I entered my name some weeks ago I have not yet received anything from Russia, and as the Russian Consulate has retained the German receipt I have at present nothing to show as evidence of membership. There is thus some inconvenience in getting a railway ticket, which must be taken before August 1st, but it is hoped that the cards will arrive one of these days from Russia. Up to July 15th the names of 447 members from Germany were entered. The Army Medical Department will be represented by Generalstabsarzt Dr. von Coler and Oberstabsarzt Dr. Schjerning, the German Surgical Association by Dr. von Bergmann and Dr. Gurlt, the Berlin Medical Society by Dr. Senator and Dr. Landau, and the Verein für Innere Medicin by Professor Gerhardt. The German representatives,

[1] A brief obituary notice appeared in our issue of July 24th.—ED. L.

Digitized by Google

Professor Virchow, Professor von Leyden, and Dr. von Coler, will be received by the Czar at St. Petersburg. Dr. Voigt, medical superintendent of vaccination in Hamburg, warns German medical men and instrument-makers not to send articles to the exhibition connected with the Congress. He states that he was invited by the Russian Society of Public Health to send a collection of vaccination instruments to the Jenner commemoration held in Moscow last year, and he did so, but he had great difficulty in getting his collection back. The articles were forwarded on Nov. 15th, and as he had received no acknowledgment by Jan. 30th he sent several letters and telegrams to the secretary of the association. No answer, however, was returned, and the Russian Consulate, moreover, declined to take any steps in the matter. After having at last applied to the German Embassy he received in the middle of April a parcel containing a portion of the collection, but a good many of the objects had disappeared.

July 29th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Congress Fever.

FOR the next two months the Continent will be labouring under this now periodic autumnal visitation which in Italy especially assumes more and more the character of a "quotidian intermittent." The international assemblage at Moscow will, of course, for the early part of August, form the chief of its "foci of infection," but it will thereafter declare itself at innumerable centres, principally (as I have stated) in the Italian kingdom. I have already announced the gathering at Bergamo of the National Medical Congress of Italy,[1] and that will be followed by another, also on a national scale—the Eighth Congress of Internal Medicine, which is to hold its sittings this year at Naples. From the Neapolitan committee I learn that Professor Guido Baccelli of Rome (where he directs the medico-clinical staff of the University Institute), Dr. Vincenzo Cervello (Professor of Pharmacology and Materia Medica in the University of Palermo), and Dr. Achille Spatuzzi (who fills the chair of Hygiene in the Naples School) have been severally approached with a view to their starting a special discussion in one or other of the subjects belonging to their personal department. This is an innovation on traditional practice in the programmes of these congresses, and though but recently tried it has worked exceedingly well in concentrating and economising attention and time, all too apt to be wasted among speakers, with whom the "parola facile" ("determination of words to the mouth") is an ethnological characteristic. Each of the distinguished professors above indicated has complied with the invitation, and Dr. Baccelli has already intimated his theme to be "La Sintesi della Malaria" (or Malaria considered in its Totality). Dr. Spatuzzi will discourse on the (historically and socially) interesting subject of the "Sommi Medici Napolitani nella Vita Publica" (the Neapolitan Leaders of Medicine in Public Life); while Dr. Cervello has still his special topic under consideration, to be announced some day soon. Besides these congresses there are others—hygienic, medico-psychological, balneary, epidemiological, ophthalmic, anthropological, medico-chirurgical—well-nigh numberless, among which may be mentioned the "Società Italiana di Laringologia, Otologia, e Rinologia," which (the third of the series) will meet on Oct. 28th next in the Roman University. The President will be Dr. Vittorio Grazzi, who holds the chairs of Aural Medicine in the Florentine and Pisan Schools, and among the papers read and discussed will be one introduced by Professor Gherardo Ferreri, of Rome, on the Value of Autoscopy in the Diagnosis and Treatment of Laryngeal Disorders; on Adenoid Affections in Italy, by Professor Giuseppe Gradenigo, of Turin; and on the Physiology of the Middle Ear, by Professor Giulio Masini, of Genoa.

Acute Dysentery in Sicily.

The health conditions of Sicily have more than a merely local interest now that (thanks to THE LANCET) the island has vindicated its claim before the professional world as a resort for the invalid and convalescent. From causes which have not yet been made clear, but prominent among which may be inferred the heat, well-nigh tropical, of the last few weeks, dysentery has appeared in the province of Messina rather formidable as to character and diffusion. Limina is the locality which has been most severely visited. Numerous cases of "dysenteria sanguinolenta," not a few of them terminating fatally, have occurred within the fortnight now ending, and the Prefecture has taken energetic measures to deal with it clinically, etiologically, and prophylactically. Dr. Fortunato, the provincial medical officer, is accordingly engaged on bacteriological examinations of the water, the food, and other sources of the malady, checking them by further scrutiny, also bacteriological, of the alvine dejections of the patients. This report, specially called for by the Ministry of the Interior, is not yet made public, but from what is already known of his findings in professional circles there is now no doubt that a considerable tract of Eastern Sicily is in presence of an epidemic closely resembling, if not in every point identical with, acute dysentery. One conclusion Dr. Fortunato and his staff have already reached, and that is that cholera, whether of the Asiatic or the milder European type, is absolutely excluded from their purview. Meanwhile, Count Buraggi, governor of the province, has issued orders of the most stringent kind, tending to isolate the epidemic and to allay the public alarm.

Typhoid Fever in Milan.

The Lombard capital—that great *entrepôt* of European and oriental travel, with its hotels so often crowded with the English-speaking world—is at present visited by typhoid fever, in all cases serious, in some fatal. According to the Ufficio Igienico Municipale there is no true *focolaio* (hot-bed) of the disease in any of the quarters of the city. The inhabitants are rather in the presence of a number of sporadic cases which the Ufficio is trying to minimise by increased surveillance over the *acqua potabile*. To this water it recommends the public to confine itself, and especially to avoid that furnished from the numerous local wells sunk in the subsoil, which have so often occasioned explosions of diphtheria as well as typhoid fever. A further injunction issued by the Ufficio forbids the eating of raw fruit, especially those *cocomeri* (water melons, green and red) so grateful to the popular palate in the dog days, but nevertheless the frequent cause of intestinal disturbance, rendering easier the lodgment of microbes in the alimentary tract—microbes (*inter alia*) conveyed in the impure ices of universal consumption.

Aug. 1st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Epidemic Mastitis.

DR. F. SCHWARZ, of Pécs, has had an opportunity of studying an outbreak of epidemic mastitis during the spring of last year, the patients being twelve women, all of whom developed the disease in the first week following childbirth. There was not one case amongst them in which he could trace the disease to lesions of the skin covering the nipples or to sores in the mouths of the suckling infants. All the patients, however, had been attended by the same midwife, and Dr. Schwarz soon ascertained that she had charge of an infant suffering from stomatitis from whom she had undoubtedly carried infectious germs to the breasts of her other patients. The mastitis ran a somewhat different course from that usually observed. The onset was marked by a severe rigor, which was soon followed by hyperpyrexia, swelling of both breasts, and rapid formation of deep abscesses. Incisions liberated a quantity of thick pus, which was found to contain large numbers of streptococci and staphylococci. The healing of the abscesses, though appropriately treated, was somewhat prolonged.

Rupture of the Urethra caused while Cycling.

This interesting case was published by Dr. S. Baumgarten in the last number of the *Orvosi Hetilap*. The patient was a man, aged twenty years, who, whilst alighting from his bicycle, unfortunately struck his perineum against the edge of the saddle. He had to be carried home, and Dr. Klein found that he had a painful swelling the size of an orange

[1] THE LANCET, July 31st, 1897.

Digitized by Google

in the perineum, and that his underclothing was full of blood, which poured freely from the urethra. The bleeding soon stopped, and the swelling gradually diminished under the application of iced compresses. Dr. Baumgarten, who, a fortnight later, was called in on account of very difficult micturition, succeeded in introducing into the bladder along the upper wall of the urethra an English catheter No. 2, which was left in position for two days. Further treatment consisted in gradually introducing catheters of larger size. The normal permeability of the urethra was restored within twenty-two days. The urethroscope, introduced at the end of the treatment, revealed in the bulbous part of the urethra a pink-coloured transverse cicatrix indicating the site and the direction of the rupture.

Post-graduate Lectures in Budapest.

The medical faculty of Budapest has arranged for the delivery of post-graduate lectures in the Hungarian language, together with practical demonstrations of interesting cases, during the summer vacations, the main object of these lectures being to afford our provincial practitioners an opportunity of obtaining an insight into the most recent advances in medicine and surgery.

July 30th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Laws Relating to Pharmacy.

THE New York Legislature amended the public health law so that the article relating to pharmacy does not apply to the sale by retail dealers or merchants of ammonia, bicarbonate of sodium, borax, camphor, castor oil, cream of tartar, dye stuffs, Epsom salts, essence of ginger, essence of peppermint, essence of wintergreen, Glauber's salts, glycerine, liquorice, olive oil, Rochelle salts, sal ammoniac, saltpetre, salts of tartar, soda, and sulphur. In the same section "usual domestic remedies" include also paregoric and essence of anise.

"Knock out Drops" Forbidden.

The New York Legislature also amended the penal code as follows: "A person (other than a duly licensed physician or surgeon engaged in the lawful practice of his profession) who has in his possession any narcotic or anæsthetic substance, compound, or preparation capable of producing stupor or unconsciousness, with intent to administer the same or cause the same to be administered to another without the latter's consent, unless by direction of a duly licensed physician, is guilty of a felony punishable by imprisonment in the State prison for not more than ten years. The possession by any person (other than as exempted in the foregoing sub-division) of any such narcotic or anæsthetic substance or compound, concealed or furtively carried on the person, is presumptive evidence of an intent to administer the same or cause the same to be administered in violation of the provisions of this section."

Abuse of Dispensaries.

The subject of the abuse of out-door medical relief is exciting much discussion in the profession. A novel form of abuse has recently been reported. A physician has been dismissed from one of the dispensaries for taking a fifty-dollar bank-note from the purse of a patient. The purse was left upon the dispensary desk while the lady entered an adjoining room to prepare for examination. The plea made to the governing board by the physician was that he had been overworked, having treated over 400 patients at the dispensary during the three days preceding the temptation which caused his fall, and that during this time he had been able to procure but one full meal. Hunger and the means to appease it may have proved too strong a combination for his overwrought nerves, but this naturally did not weigh with the board.

The Influence of the "Drink-habit" in Causing Crime.

Dr. Wines, of Illinois, one of the most eminent statisticians of the United States, describes some of the statements made on this subject as utterly wild and irrational, without any support, in fact. Such a statement was that 90 per cent. of cases of pauperism, crime, insanity, &c., are due to drink. To say that was pure folly. There are pauperism and crime to be found in Mohammedan countries as well as in Christian countries. Drink is not a cause of crime; the cause of crime lies deeper—in the depravity of the human heart, not in any material thing. He then briefly analyses the police returns of twelve of the largest cities of the United States, showing that about half of the arrests are protection arrests, not for crime, and a large number of the residue are for petty misdemeanours, violations of city ordinances, &c., leaving about one quarter for serious offences. The average of arrests per saloon per year is between six and seven of all sorts, and eliminating the protection arrests and the petty misdemeanours it turned out that the average is one and a half arrests per saloon. Wardens of prisons who are new generally think intemperance the cause of crime. After an experience of a dozen years or so they generally see differently. Liquor never puts into a man a new impulse—it removes the restraint on impulses which he has already. And he remarked that in a number of prisons where convicts are confined for murder there are about as many total abstainers as drinkers.

Caring for Epileptics.

Dr. Rutter, of the Hospital for Epileptics, of Ohio, who has had great success in the treatment of this class, gives a detailed account of the measures adopted, and one interesting feature is that of diet, which he has found was very important. A free meat diet he condemned, and it is used only for the mid-day meal, and then only fresh beef, roasted or boiled mutton, fowl, or fish. Meals are served in courses to ensure deliberation in eating. Fruit, fresh or if not canned or dried, is given freely, and is the principal article for breakfast and supper, supplemented by some cereal and milk. No pastry is allowed, and no article is fried. Bread is usually given stale. Coffee is given for breakfast and milk *ad libitum* for other meals. Many vegetables, like cabbage, cucumbers, &c., have not been found harmful.

July 28th.

Obituary.

HENRY THOMPSON, M.A., M.D. CANTAB, F.R.C.P. LOND.,

SENIOR FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE; CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL.

THE death, at the advanced age of eighty-one years, of Dr. Henry Thompson removes from our ranks one of the most learned members of the profession and one of the most unassuming. He was born at Workington, Cumberland, and became a distinguished scholar of Shrewsbury School, then under the headmastership of Dr. Samuel Butler. The well-known "Sabrinæ Corolla" contains some exquisite Greek and Latin verses from Thompson's pen, proving that he had an early bent towards classical studies, which culminated later in his receiving a Fellowship at St. John's College, Cambridge. He elected to follow the profession of medicine, and studied at St. George's Hospital, obtaining his M.D. degree in 1853 In 1855 he was elected assistant physician to the Middlesex Hospital, where he also lectured on Materia Medica from 1855 to 1869, became physician four years later, and in 1872 senior physician. He retired from the acting staff in 1879, but continued to reside in London until his death.

Dr. Henry Thompson was little known in the medical world outside his own hospital, but there he was held in great esteem. Enabled to devote himself largely to hospital work—for he practically had no private practice, nor did he desire to have any—he was most regular and punctual in his attendance, and notable for the care with which he examined and treated his patients. His clinical observations were marked for their accuracy and his judgment was well balanced and sound. He did not teach much at the bedside, but those who had the good fortune to serve under him as house physicians are unanimous in their testimony to his qualities as a physician. His clinical lectures (on the preparation of which he took great pains) were models of terse and thoughtful exposition, and prove that his knowledge was wide and accurate. Some of them have appeared in these columns, and after resigning the office of physician he collected a few into a volume of clinical lectures and cases with commentaries (Churchill, 1880), which is full

Digitized by Google

of suggestiveness and practical insight. Those who best knew him have regretted that he did not take a more prominent place, for there can be no question that he was a physician of the first order. But he was as remarkable for his modesty and freedom from ambition as he was for his high talents; he was contented with the life he had chosen, and no one can deny that he did not faithfully and scrupulously fulfil his duties as an ideal hospital physician. He was a man of fine presence, kindly and gentle in manner, earning the admiration and affection of pupils and colleagues. Of late he had become physically very feeble, and his death occurred after a brief illness, an attack of diarrhœa causing exhaustion, from which he could not rally.

Medical News.

VICTORIA UNIVERSITY.—On July 30th the following degrees were conferred by the Vice-Chancellor (Dr. N. Bodington) in the Owens College:—

MASTER OF SCIENCE.

William Henry Moorby, Owens College.

BACHELOR OF MEDICINE AND OF SURGERY.

Second-class Honours.—William Hirst Bateman, Owens College; Joseph Everett Dutton, Walter Graham, and Arthur Stanley Griffith, University College; Harold Hartley, Owens College; David Garnett Hurter, University College; Charles Herbert Moorhouse, Yorkshire College; John Henry Sheldon, Owens College; and Robert Sutherland, University College.

Mark Aungier, University College; Thomas Fletcher Bamford, Owens College; Robert Wilfred Bollans, Yorkshire College; John James Butterworth and James Bertram Clarke, Owens College; Francis Darlow and Philip Henry Fearnsides, Yorkshire College; Henry Martyn Henderson, University College; Arthur Thomas Lakin, Owens College; John Reginald Lambert, Yorkshire College; Alexander Lawson, Owens College; John Harold Mason, Yorkshire College; John Mooney and Archibald McLelland Pilcher, Owens College; Francis Stanhope Pitt-Taylor, University College; John Prestwich, Frank Pritchard, Alexander Low Rhind, and Alfred Wightwick, Owens College; and James Hayward Willett, University College.

In the Faculty of Medicine the following candidates have been successful in the subjects indicated:—

FIRST EXAMINATION.

Part II. Biology.—Roy Appleton and P. W. Ashmore, Yorkshire College; F. H. S. Ashworth, J. B. Barnes, and J. H. Battersby, Owens College; H. M. Berry, University College; C. H. Booth, Yorkshire College; Neville Bradley, University College; S. B. Brentnall, Owens College; R. N. Butterworth, and W. H. Canter, Yorkshire College; J. B. Cook, Alexander Cran, and E. N. Cunliffe, Owens College; S. W. Davies, University College; A. M. Deane, Yorkshire College; Tom Eastham, J. E. Floyd, and F. W. Gatenby, Owens College; G. W. Gelderd, University College; P. H. Green, J. W. Greenwood, and P. T. Harding, Owens College; F. W. Hayes, Yorkshire College; Godfrey Heathcote and Rowland Heathcote, Owens College; J. P. Henderson and A. G. Jackson, University College; S. J. C. Johnson, C. P. Lapage, and Charles Mackey, Owens College; H. C. McManus, University College; C. T. Matthews, Yorkshire College; Herbert Maxfield, Owens College; J. S. W. Nuttall, University College; G. G. Parkin and R. T. A. Patchett, Owens College; H. D. Pearson, Sydney Platts, and M. B. Potts, Yorkshire College; H. H. Rayner and Arthur Richmond, Owens College; William Rotherham, University College; Edwin Saville, Yorkshire College; F. R. Sawdon, G. H. Shaw, W. F. Shaw, S. W. Swindells, and H. G. Tansley, Owens College; J. C. Teasdale and M. G. Walker, Yorkshire College; H. C. Waterhouse and Alwyn Wharton, Owens College; R. G. Wills, University College; E. M. Wilson and J. G. Woolham, Owens College; and F. W. B. Young, University College.

SECOND EXAMINATION.

A.—Anatomy and Physiology.—S. W. Battle, Yorkshire College; George Binns, J. P. Brown, and W. J. Butcher, Owens College; J. S. Byrne, University College; H. H. Bywater, E. W. Falconer, P. A. L. Foulds, Henry Holt, H. S. McLellan, F. A. Morrison, E. S. Nichol, T. E. Regan, and Harry Scholefield, Owens College; G. M. Sharpe, Yorkshire College; Harold Snape, Owens College; W. A. Stott, Yorkshire College; Edward Swales, University College; R. N. West, Owens College; R. D. Willcocks, University College; and P. G. Williamson, Owens College.

B.—Materia Medica and Pharmacy.—Granville Ainsworth and Arthur Anderson, Owens College; E. W. Anderton, Yorks College; M. B. Arnold, E. M. Ashcroft, and J. T. Bailey, Owens College; Herbert Bates, University College; A. D. Beckett, Owens College; Philip Benington, University College; A. T. Blease, Owens College; Henry Brown, Yorkshire College; P. A. Browne and C. W. Budden, University College; Fred. Bullough, E. R. Cooper, J. M. Cort, Daniel Cowin, and C. W. Crawshaw, Owens College; J. L. Dimond, University College; T. H. B. Dobson, Owens College; W. F. Ellis, Yorkshire College; R. J. Ewart, University College; A. H. B. Fletcher, Yorkshire College; H. E. Fox, Mercier Gamble, Walter Garstang, D. G. Gellatly and Reginald Gordon, Owens College; Frederick Griffith, University College; F. G. Hack, C. R. Hall, and W. D. Hamer, Owens College; F. W. Harrowell, Yorkshire College; L. C. Johnson, Owens College; R. E. Kelly, University College; Reginald Lawrence, C. H. Lee, H. S. Lister, and James McIlraith, Owens College; J. C. Mann, University College; H. J. Moon, Owens College; T. F. Pugh, University College; P. A. H. Radcliffe, Yorkshire College; Albert Ramsbottom and Sidney Renshaw, Owens College; E. E. Roberts, University College; J. H. Sutcliffe and R. W. Taylor, Yorkshire College; Thomas Tierney, Owens College; C. R. Willans, Yorkshire College; T. B. Williams, Owens College; F. P. Wilson, University College; and J. D. Windle and W. A. B. Young, Owens College.

FINAL EXAMINATION.

Part I.—D. A. Alexander and J. W. Anderson, University College; D. A. Ashton and J. T. Auld, Owens College; J. W. Barber, Yorkshire College; T. T. Bark, University College; H. P. Clarke and John Craig, Owens College; H. R. Cross, Yorkshire College; William Crozier and S. S. Depree, University College; E. C. Dutton and E. W. Floyd, Owens College; Joseph Goodall, Yorkshire College; J. P. H. Greenhalgh and Roland Hamer, Owen's College; H. F. Hart, University College; T. W. Hart, Owens College; E. M. Hime, Yorkshire College; Frederic Hoyle, Owens College; F. W. Inman, University College; H. H. McNabb, E. J. Martin, and John Mooney, Owens College; S. C. Moore, University College; Harry Osborne, W. H. Richardson, and William Rigby, Owens College; Ambrose Spong, Edward Trotter, and Edward Turton, Yorkshire College; G. C. Walker and L. S. Whitwam, University College; and T. H. Wignall and O. H. Woodcock, Owens College.

Part II.—Mark Aungier, University College; T. F. Bamford and *W. H. Bateman, Owens College; R. W. Bollans, Yorkshire College; J. J. Butterworth and J. B. Clarke, Owens College; Francis Darlow, Yorkshire College; *J. E. Dutton, University College; P. H. Fearnsides, Yorkshire College; *Walter Graham and A. S. Griffith, University College; *Harold Hartley, Owens College; H. M. Henderson and *D. G. Hurter, University College; A. T. Lakin, Owens College; J. R. Lambert, Yorkshire College; Alexander Lawson, Owens College; J. H. Mason, Yorkshire College; John Mooney, Owens College; *C. H. Moorhouse, Yorkshire College; A. M. Pilcher, Owens College; F. S. Pitt-Taylor, University College; John Prestwich, Frank Pritchard, A. L. Rhind, and *J. H. Sheldon, Owens College; *Robert Sutherland, University College; Alfred Wightwick, Owens College; and J. H. Willett, University College.

* Awarded second-class honours.

In the Faculty of Science the following candidates have passed the Intermediate Examination:—

D. M. Alexander and Helen P. Auld, University College; A. R. Dwerryhouse and E. L. Gill, Yorkshire College; J. L. Hawkes, University College; Alexander Hodgkinson, Owens College; and C. O. Jones, W. G. Lloyd, and E. A. Rosenheim, University College.

The Diploma in Public Health has been awarded as follows:—

J. H. Ashworth, H. P. Butterworth, W. E. Davies, and T. W. H. Garstang.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Paul Silex, First Assistant of the University Ophthalmic Clinic, has been promoted to an Extraordinary Professorship.—*Breslau:* Dr. Henle, of the University Surgical Clinic, has been recognised as *privat-docent* in Surgery.—*Montpellier:* Dr. Rodet, *agrégé*, has been appointed Professor of Microbiology.—*Paris:* Dr. R. Blanchard, *agrégé*, has been appointed Professor of Medical Natural History.—*Zürich:* Dr. Georg Ruge, Professor of Anatomy in Amsterdam, has been offered the Chair vacated by Professor Philipp Stoehr on his migration to Würzburg. He was formerly Gegenbauer's assistant in Heidelberg, and has written a good deal on Descriptive and Comparative Anatomy and also on Embryology.

THE CHOLERA SEASON IN INDIA.—Although there is a certain amount of cholera and choleraic diarrhœa in Bombay and Poona, and a somewhat increased prevalence of these diseases at Sholapoore, it appears that the summer in India generally has so far been a healthy one as regards epidemic disease. Cholera, which threatened to be severe in the central parts of the country in the spring, has died out, according to the *Pioneer Mail*, except in the Deccan, and the plague has practically now ceased as regards its epidemic form.

MANCHESTER SOUTHERN HOSPITAL.—The annual meeting of the Manchester Southern Hospital was held on July 21st in the Lord Mayor's Parlour, Sir John Harwood presiding. The report showed that 5656 cases have been treated during the year. At the Clifford-street branch of the hospital 146 women and 283 children had been admitted as in-patients, while 994 women and 2820 children attended as out-patients. There were also 1233 maternity cases treated at their own homes and 180 admitted as in-patients. The income for the year was £2596 and the expenditure £3644, showing a deficiency of £1048. It was stated by the secretary that the trustees of the late Mr. David Lewis had offered to provide a building fund for a new hospital or amalgamated institution consisting of the Southern Hospital and St. Mary's Hospital, and the committee of the Southern Hospital were willing to accede to the proposals; but to their regret the scheme had not been carried out.

HEALTH OF LIVERPOOL.—435 births and 240 deaths were registered in the city during the week ending July 17th. The patients under treatment in the city hospitals for infectious diseases numbered 261; 40 patients were suffering from typhoid fever and 196 from scarlet fever.

MEDICAL MAGISTRATES.—Mr. Wm. J. Morton, M.D. Aberd., L.R.C.P., L.R.C.S Edin., of Inverell, New South Wales, has been appointed a visiting justice to the gaol at Inverell.—Mr. James Jamieson, M.D., Ch.M. Glasg., of Melbourne, Victoria, Australia, has been appointed a Justice of the Peace.—Mr. Thos. A. Grieves, L.R.C.P. Lond., M.R.C.S. Eng., of Wyalong, New South Wales, has been appointed a Justice of the Peace for the colony.

ROCHDALE INFIRMARY.—In commemoration of the Queen's long reign the people of Rochdale resolved to add a new wing to their infirmary, and this extension was formally opened by Lord Stanley, M.P., on July 24th. The proceedings commenced by the mayor and corporation, preceded by a band of music, walking in procession from the Town Hall to the infirmary. Lord Stanley was then presented with a gold key, with which he unlocked the door of the new building. In the course of an address delivered by Mr. S. Turner, president of the infirmary, it was stated that the committee had for some time been desirous of enlarging their premises, and during the present year the gift of a sum of £18,000 received from the trustees of the late Mr. James Holden enabled them to erect this extension, which will be designated the Holden Wing. The Holden trustees had on a former occasion given £2000, and other contributions have resulted in the formation of a guarantee fund amounting to £24,000.

DIPHTHERIA IN LONDON.—In the four weeks ended on July 17th the amount of diphtheria in London, as gauged by the certificates of notification, was in excess of the preceding period of like length. In fact, we have to go back to the four-weekly period ended on Nov. 28th last to find a total of notifications higher than that of the July period, although it is true that the five-weekly period which concluded last year, ending on Jan. 2nd, 1897, also yielded a larger weekly average of cases notified. In the July period the notified attacks numbered 1011, yielding a weekly average of 253 against averages of 224 in June, 288 in December, and 290 in November. But if we compare the July period of this year with that of 1896 we find that the record of last year exceeds the current one by 58 notifications in the four corresponding weeks. In the July period of the present year all the sanitary areas of London were invaded; five of them had respectively 50 or more notified attacks, with an aggregate of 331, whilst other five had only 14 notifications of diphtheria amongst them. The registered deaths in the June period were 137, and in July 135; but the per case rates of mortality varied more, being in June 15·3 and in July 13·3 per cent. of the notifications. In July of last year the deaths were 167, and the rate 15·6 per cent.; in November, 220 and 19·0 per cent. respectively; and in December (five weeks) 257 and 17·8 per cent. respectively. Thus, with an increasing amount of diphtheria, we seem this year to have, for the time at least, a milder form of the disease.

PRESENTATIONS TO MEDICAL MEN.—Mr. Richard Youl, M.D. St. And., M.R.C.S Eng., City Coroner of Melbourne, Victoria, Australia, was the recipient, on May 26th last, of an enlarged and framed photograph of himself as a token of esteem.—Mr. Edwin Hinchcliff, M.D. Edin., M.R.C.S. Eng., received on his leaving the Bendigo District, Victoria, Australia, a handsome present from the Sandhurst No. 1 Fire Brigade, of which he was the honorary surgeon.—Mr. L. F. Praagst, M.B., C.M. Melb., late medical superintendent of Horsham District Hospital, Victoria, Australia, was, on May 27th last, given a complimentary entertainment on his leaving the district.—Mr. L. G. Fraser, M.B., B.S. Durh., of North Shields, at a meeting on the 27th ult. of the North Shields Centre of the St. John Ambulance Association, was presented by the women's class with a lamp, and by the men's with an illuminated address, in recognition of his instructive lectures to the classes.—At the annual meeting of the Western Branch of the British Dental Association, held at Exeter on July 23rd, Mr. J. T. Browne-Mason, L.D.S. Eng., the honorary treasurer, was presented with a pair of silver bowls, and Mr. T. A. Goard, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S., the honorary secretary, received a silver salver. The presentations were made by Mr. Dudley, of Bath, on behalf of the members of the western branch of the association.—Certificates in connexion with St. John Ambulance classes at Trethosa and Nanpean were presented on July 22nd, when Mr. A. Shaw, M.B., C.M. Glasg., was the recipient of a handsome riding whip and a silver butter cooler in appreciation of his services as honorary lecturer.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—At a meeting held on July 16th, Dr. Milligan (President) in the chair, Mr. George Stoker showed two cases of Suppurative Otitis and a case of Ozæna, which had been treated successfully by oxygen gas after prolonged treatment by other methods had given a negative result. The gas employed was a mixture of oxygen and purified air, as pure oxygen was, as a rule, found too irritating to be employed alone.—Dr. Macnaughton Jones pointed out that the great difficulty in treating cases of suppurative otitis lay in keeping the patients a sufficient time under observation to enable the local treatment to be efficiently carried out. He had treated ozæna with oxygen by means of Mr. Stoker's apparatus without any success.—Mr. Bark showed a case of Epithelioma of the Right Vocal Cord removed by thyrotomy. The patient, aged forty-one years, had suffered for two years from hoarseness due to the presence of a greyish white papillated growth in the right vocal cord, which, together with the ventricular band and the arytenoid cartilage, was removed after thyrotomy, the patient making a rapid and uneventful recovery.—Mr. Lennox Browne reported a case of Epithelioma of the Soft Palate in a man aged forty-eight years. The soft palate was greatly infiltrated and the seat of a warty growth which extended to the faucial pillars, but did not appear to involve the tonsils; the tongue and larynx were perfectly free. The growth was successfully removed under cocaine, and the patient made an excellent recovery, with a rapid increase in weight. The growth proved on examination to be a typical epithelioma.—Dr. Middlemass Hunt opened a discussion on "The Preliminary Training and Methods of Operating on Laryngeal Growths," and referred to the great assistance cocaine was in intra-laryngeal operations, both in shortening the time required to complete the operation and simplifying the necessary manipulation. It did not, however, do away with nervousness on the part of the patient, and certain preliminary training was necessary in most cases. Under cocaine anæsthesia cutting forceps had taken the place of snares, guillotines, caustics, &c., and the rough and uncertain methods of Voltolini had utterly disappeared.—Dr. Milligan and others took part in the discussion.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Workmen's Compensation Bill.

IN the course of the consideration of this Bill in the House of Lords an amendment was inserted providing that if an injured workman objects to the employer's medical man or to his report he may submit himself for examination to one of the medical men appointed for the purposes of the Act, whose certificate shall be conclusive evidence as to his condition.

London University Commission Bill.

Although this Bill got through all its stages in the House of Lords, when it reached the House of Commons it was threatened with serious opposition from various quarters; and in view of the pressure of other work and the arrangements for concluding the session Mr. Balfour decided to withdraw it. In intimating this decision he expressed the hope that next session the Government may be in a position to deal with the subject.

London Water Question.

In both Houses of Parliament the London water question has been a good deal discussed during the week. In the House of Lords there was a second reading debate on the Metropolitan Water Companies Bill, in the course of which Lord James of Hereford explained in detail the nature of the inquiry to be carried on by the Royal Commission. In the House of Commons Mr. Chaplin answered a great many questions with reference to shortness of supply in East London.

HOUSE OF COMMONS.

THURSDAY, JULY 29TH.

The Army Medical Department.

Captain Norton asked the Under Secretary of State for War whether it had been brought to his notice that officers of the Army Medical

Digitized by Google

Department suffered severely from frequent moves at short notice, coupled with difficulty of obtaining leave, to such an extent that an officer of eleven years' service serving at home had recently to pay about £30 to enable him to obtain a part of the ordinary leave to which he was entitled by regulation, although the leave in question was for urgent private affairs—namely, to visit a sick wife at his proper station, he being on detachment; and whether he would take steps to deal with these hardships.—Mr. Brodrick replied: Officers of the Army Medical Staff are moved from station to station as seldom as possible and only when the necessities of the public service demand. Ordinarily a departmental officer can only have leave of absence when it does not cause additional expense to the public; but as the home establishment is under strength and inconvenience resulted, arrangements have been made whereby a substitute for an officer on leave is provided without expense to that officer when the establishment of the district is not full.

Beri-beri in Ireland.

Mr. Sheehy asked the Chief Secretary to the Lord-Lieutenant of Ireland whether he was aware that the medical superintendent of the Richmond Asylum had been complaining about the overcrowded condition of his institution in his annual reports since 1886 to the governors; and that a contract, involving nearly a quarter of a million sterling on the new asylum at Portrane, was given away by the Board of Control, which was an unrepresentative body, without consultation with the Board of Governors; whether he would state to the House the amount of money expended on temporary buildings which had been condemned by Dr. Patrick Manson, of London, and by Sir Thornley Stoker, of Dublin; and whether his attention had been called to the statement in the Inspectors' Report for 1891 that the Richmond Asylum was originally constructed for 600 patients, that there were now considerably over 1800 patients in the asylum, and that the additional temporary accommodation did not even provide for the increase in the numbers, since the inspectors reported in 1890 that the congestion paralyses every effort to treat the insane.—Mr. Gerald Balfour replied that the fact was as stated in the first paragraph. It was not true that the contract for the Portrane Asylum was given away by the Board of Control without consultation with the Board of Governors. The expenditure on the temporary buildings which were erected with the concurrence of the governors amounted to about £12,000. The medical gentlemen referred to considered wooden buildings unsuitable for the treatment of beri-beri patients, but the buildings erected at Richmond had been designed with every possible attention to sanitary requirements, and were, in the opinion of the inspectors of lunatics, suitable for the accommodation of the insane.

MONDAY, AUG. 2ND.

Sale of Food and Drugs Bill.

At this sitting Mr. Chaplin formally introduced a Bill to amend the Acts relating to the sale of food and drugs. He explained that it gives effect to some of the least controversial of the recommendations of the Select Committee on Food Products Adulteration, but that it was only introduced now in order that during the recess the general drift of opinion on the subject might be ascertained.

The Vaccination Question.

During the discussion in Committee of Supply on the vote for the salaries and expenses of the Local Government Board Mr. Channing complained of the delay in dealing with the vaccination question, and suggested that in the meantime a circular should be issued to boards of guardians advising them not to repeat prosecutions.—Mr. Chaplin said that after he received the report of the Vaccination Commission he found it necessary to have further inquiries made by the experts of the department, and the results of these inquiries had only recently reached him. From a hasty perusal of them he was led to believe that sooner or later there would be a complete reform of all the laws relating to vaccination.

TUESDAY, AUG. 3RD.

Vaccination Commission.

Sir M. White Ridley, in reply to Colonel Dalbiac, said that the appendices to the report of the Royal Commission on Vaccination could be presented at once, and would probably be circulated in two or three weeks. The delay was attributable to the fact that the necessity for a separate presentation of these appendices was, through some misunderstanding, overlooked.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ATKINSON, J. M., M.B. Lond., D.P.H. Camb., has been appointed Principal Civil Medical Officer at Hong Kong, vice Ayres.

BENNETT, F. G., L.R.C.P., L.R.C.S Edin., L.F.P.S. Glasg., has been appointed *pro tem.* Officer of Health for the Shire of Alberton, Victoria, Australia.

BLACKMORE, G. J., M.B., C.M. Edin., has been appointed Assistant Medical Officer for the Workhouse of the Nottingham Union, vice W. P. Byford, resigned.

BOND, F. S., L.R.C.P. Lond., M.R.C.S. Eng. has been appointed a Public Vaccinator at Bruthen, Victoria, Australia.

BUICK, JAMES, M.B., Ch.M. Glasg., has been appointed Resident Surgeon to the Bendigo Hospital, Victoria, Australia.

CLAYTON, F. M., M.B., B.S. Durh., has been re-appointed Medical Officer of Health by the Felling Urban District Council.

CONNAL, JAS. G., M.B., M.S. Glasg., has been appointed a Physician to the Throat and Nose Department of the Glasgow Central Dispensary.

DAVIES, J. L., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Munslow Sanitary District of the Ludlow Union.

FRANCIS, H., M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Arnold Urban District Council.

GOING, J. A., M.R.C.S. Eng., has been appointed Medical Officer to the Mungindi Hospital, New South Wales.

GOWAN, B. C., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Hendon Rural District Council.

HARDING, R. F., L.R.C.P., L.R.C.S. Irel., has been appointed Assistant Medical Superintendent to the Hospital for the Insane, Goodna, Queensland.

HARRIS, G. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Glenfield Sanitary District of the Blaby Union.

HENRY, L., M.D. Wurzb., L.R.C.P. Lond., has been appointed a Certifying Medical Officer under the Factories and Shops Act for the Metropolitan District of Victoria, Australia.

HINE, A. E. B., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed a Public Vaccinator for South Australia.

JAMIESON, JAS., M.D., Ch.M. Glasg., has been appointed an Official Visitor to the Yarrow Benevolent and Metropolitan (Kew) Lunatic Asylums, Victoria, Australia.

KELLY, H. G., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator at Pyramid Hill, Victoria, Australia.

LAYTON, HENRY A., M.R.C.S. Eng., L.R.C.P. Edin., has been appointed Medical Superintendent to the Cornwall County Asylum, Bodmin, vice Richard Adams, resigned.

LIDDLE, P. H., M.B., Ch.B. Melb., M.R.C.S. Eng., has been appointed Officer of Health for the Shire of Mansfield, Victoria, Australia.

MCDOUGALL, MARY ROSS, M.B., C.M., has been appointed Resident Medical Officer to the Edinburgh Hospital for Women and Children.

MORCOM, A., L.R.C.S., L.M. Edin., has been re-appointed Medical Officer of Health by the Luton Rural District Council.

READ, S. J. D., M.B., Ch.B. Melb., has been appointed a Resident Surgeon to the Rockhampton Hospital, Queensborough.

SHAW, F. C. S., M.B., Ch.M. Syd., has been appointed a Government Medical Officer and Vaccinator for the District of Emmaville, New South Wales.

SLADE-KING, B. J., M.D. Edin., L.R.C.P. Lond., M.R.C.S., D.P.H. Edin., has been re-appointed Medical Officer of Health by the Dulverton Rural District Council.

THANE, E. H., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed a Surgeon to the Wagga Wagga Hospital, New South Wales.

THOMSON, WM. E. F., M.D. Edin., has been appointed Professor of Physiology at the Anderson's College Medical School, Glasgow.

VENTERS, ISABEL, M.B., C.M., L.R.C.P. & S. Edin., has been appointed Assistant Medical Officer to the Edinburgh Hospital for Women and Children.

WARRINGTON, W. B., M.D. Lond., M.R.C.P., has been appointed Demonstrator in Pathology in University College, Liverpool.

WILLIAMS, J., M.D. Edin., M.R.C.S. Eng., has been appointed a Member of the Medical Board of Victoria, Australia, vice J. D. Tweeddale.

WILSON, FRANCIS KENNETH, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to Westminster Hospital.

WORTS, H., L.R.C.P. Lond., M.R.C.S., has been re-appointed a Surgeon to the Essex and Colchester Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ADDENBROOKE'S HOSPITAL, Cambridge.—Resident House Physician. Salary £65 per annum, with board, lodging, and washing in the Hospital.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board, washing, lodging, &c.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE, 101, Great Russell-street, London, W.C.—Bacteriologist to the Antitoxin Department at Sudbury. Salary £200 per annum, with dwelling accommodation on the premises.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House Surgeon. Rooms, coals, and lights provided.

Births, Marriages, and Deaths.

BIRTHS.

ARNOLD.—On July 31st, at Oxford-road, Manchester, the wife of F. S. Arnold, M.B., of a son.

ETTLES.—On July 20th, at The Crescent, Minories, E.C., the wife of W. J. McCulloch Ettles, M.D., of a son.

HAWKE.—On July 27th, at Valley-road, Shortlands, the wife of Edward D. H. Hawke, L.R.C.P. Lond., M.R.C.S., of a son.

HUBBARD.—On July 31st, at Hemel Hempstead, the wife of Arthur John Hubbard, M.D., of a son.

PRICE.—On July 31st, at Firside, Walton-on-Thames, the wife of Arthur E. Price, M.B. Lond., L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

ALLAN—CLARK.—On July 31st, at the Church of St. Mary Magdalene, Latimer, Bucks, by the Rev. F. C. J. Long, Arthur Percy Allan, M.B., B.S. Lond., of South Croydon, youngest son of the late John Allan, of Calcutta and Ladbrook-grove, W., to Margaret Hannah, daughter of the late Richard Clark, of Amersham.

BUCHANAN—WOODHOUSE.—On July 31st, at the parish church, Weybridge, Archibald Graham Buchanan, L.R.C.P. Lond., M.R.C.S., Liss, Hants, to Mabel Berkeley, second daughter of Henry Melvill Woodhouse, of Brackenhurst, Weybridge.

HANDS—WHEELER.—On July 29th, at All Saints' Church, Cheltenham, Francis William Hands, L.D.S. Eng., to Margaret Ursula Langham, youngest daughter of the late Robert Wheeler, solicitor, of Cheltenham.

THORNTON—SHEERMAN.—On July 28th, at Holy Trinity, Beckenham, Frank B. Thornton, M.B., B.S. Lond., of Derby, to Florence Anne, eldest daughter of Henry Sheerman, of Newlands Park, Sydenham.

DEATHS.

BLISS.—On July 28th, at Perrysfield House, Oxted, Surrey, Francis Henry Bliss, M.B., eldest surviving son of Sir Henry Bliss, in his 29th year.

PALMER.—On July 28th, at 87, Harcourt-terrace, S.W., Edward Palmer, M.D., in his 81st year.

TOMLINSON.—On July 31st, at Belgaum, India, from typhoid fever, Surgeon-Lieutenant Lionel Philip Tomlinson, A.M. Staff., younger son of Brigade-Surgeon E. D. Tomlinson, of 8, Earl's-avenue, Folkestone. (By telegram.)

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

A QUERY IN OPHTHALMIC SURGERY.

To the Editors of THE LANCET.

SIRS,—May I ask the favour of an answer to this question: A young maiden girl, aged twenty-one years, perfectly healthy, breathing healthy mountain air all the year round, has a ripe cataract in one eye; the sight of the other eye is perfect. This cataract is not traumatic. Would it be desirable to operate? I am, Sirs, yours faithfully,

Llandilo, Aug. 4th, 1897. X. Y. Z.

A HEROIC REMEDY.

To the Editors of THE LANCET.

SIRS,—The enclosed cutting from to-day's issue of a well-known evening paper is not without interest:—

(35,811) EYES.—Will "Bornall, M.D.," please explain? He says (Reply 35,513):—"Paint the part with chloroform of aconite." The part in question is my eyes. How do I paint them?—*Oculist.*

"Oculist" seems to have sought the professional guidance of the gentleman responsible for the inquiry column of that journal, who prescribes with equal confidence and equal light-heartedness for a bruised finger and for an ovarian tumour. The extraordinary advice given in reply to his inquiry seems to have awakened in his mind some faint doubts as to his mentor's infallibility. Hence the mild protest thinly veiled by to-day's query. It would be interesting to know on whose shoulders the responsibility would have rested if this confiding sufferer had adopted the remedy proposed. I am, Sirs, yours faithfully,

T. R. HENDERSON, M.B., C.M. Edin.

Ivycroft, Balham, S.W., July 31st, 1897.

Verax.—The M.R.C.S. of the date mentioned was considered to possess a medical qualification. If a registered medical practitioner were required he clearly was able to fill the post.

SUSCEPTIBILITY OF CHILDREN TO HOSPITALISM.

A CORRESPONDENT in America writes to us as follows: "There is a tendency just now towards the multiplication of special hospitals for infants (at any rate, so it is in America), and it may not be out of place to sound a note of warning on some of the dangers attending such a course. Children should only be sent to hospitals when it is impossible to care for them properly at their own homes and in cases of acute illness. This statement applies particularly to infants; the younger the child the greater the pernicious influence of hospital life, and instances of quick or satisfactory recoveries in a hospital are rare. This fact has been exemplified in a striking manner in several of the large hospitals in France, especially in the case of 'l'Hôpital Trousseau,' which was characterised a year or two ago as a veritable death-trap. Dr. Chapin, of New York, has lately drawn attention to the great susceptibility of infants to hospitalism; he says: 'One of the first conditions to be noted is a progressive loss of weight that is not dependent on the original disease, as it often takes place after recovery when the child is not sent out soon enough. This atrophy bears an inverse ratio to the age and is especially marked under six months. Beginning atrophy, not depending upon a lesion, should be an indication for immediate discharge from the hospital. If it gets beyond a certain point no change of environment or food will save the infant. As a general rule young infants should not be kept in hospital longer than a fortnight." Another danger that is most difficult to guard against is the great risk of contagion, and the larger the hospital the greater the danger. The nursing should be of the highest possible description; ordinary efficiency in this respect will not suffice. In many cases a good nurse should be supplied to four or five infants, and in some a nurse may be required for only two patients. The infants should be under the most careful oversight, and at the first signs of hospitalism should be discharged without delay."

Undergrad.—What has been told our correspondent is correct concerning the diploma in question. For details he should consult the Students' Numbers of THE LANCET for the past nine years.

G. W.—No. The more usual style is Dr. ——, provided that the owner of the card is a graduate in medicine of a recognised university.

F. W. ELLISON FUND.

The following sums have been received:—

	£	s.	d.
THE LANCET Relief Fund	15	0	0
Sir T. Smith	10	10	0
Dr. Lauder Brunton ...	5	5	0
Mr. Howard Marsh ...	5	5	0
Sir Dyce Duckworth ...	3	3	0
Mr. W. H. Hatfield ...	2	2	0
Mr. H. A. Francis, of Victoria, British Columbia	2	2	0
Vicar of St. Paul's, Macclesfield	1	1	0
Mr. W. Bruce Clarke ...	1	1	0
Mr. Harrison Cripps ...	1	1	0
K. W. M.	1	1	0

Fair Play.—Our attention is called to the advertisements of "Camwal Table Waters and the testimonials from leading practitioners of Brighton by which they are supported. We entirely agree with our correspondent that such testimonials are to be disapproved, as they amount to an advertisement of the medical man who writes the testimonials. We think, however, that the General Medical Council could hardly be expected to give time to the consideration of the matter, while we believe that the medical men in question have been sinned against.

Digitized by Google

"THE PATHOLOGY OF DISTEMPER."

To the Editors of THE LANCET.

SIRS,—I do *not* say that distemper in the dog will produce scarlet fever or diphtheria in human beings, but that it is only a stage in the life-history of these organisms, comparable to the tæniæ. Although we do not know the intermediate host at present, despite the high authority of the men you mention, I believe we shall be able to find one. How do you explain the clinical symptoms, which correspond so closely? I am, Sirs, yours truly,

Ashton-under-Lyne, Aug. 1st, 1897. F. W. MANN, M.B. Edin.

Ellershouse.—We do not know the book in question, so that we cannot recommend it or one "giving similar information." But perhaps our correspondent refers to the well-known little book by Mr. Jukes de Styrap, entitled "A Code of Medical Ethics," and published by H. K. Lewis, Gower-street, E.C.

O. L. is referred to his or her medical attendant. Firstly, we do not prescribe or suggest medical treatment, and secondly, we do not understand our correspondent's question.

A CORONER ON DEATH CERTIFICATES.

THE *Western Morning News* of July 20th and July 24th gives an interesting account of the proceedings at an inquest held at Gwennap, near Redruth, on July 19th. The deceased was nine months old and was the son of a labourer; the body had been buried, but was exhumed for the purpose of the inquest. Mr. William Hichens, who was deputy for his brother, the parish medical officer, said that he visited the deceased on March 4th, March 7th, and May 31st, and found that he had slight bronchitis. On July 9th he received an urgent request for a death certificate and gave a note worded as follows: "I hereby certify that six weeks ago I saw the baby of Mrs. Samuel Collins. It was then suffering from a slight attack of bronchitis. Since then I have not seen it." That was not a certificate; he told the grandmother that he did not know the cause of death and could not certify. Mr. Thomas Curnow, the registrar of births and deaths, said that on the information given him by the child's grandmother and the note from Mr. Hichens he registered the death as not certified. He had known the people a long time. The registrar had absolute discretionary power as to registering a death except where it was sudden, violent, suspicious, or the cause unknown. The coroner (Mr. Laurence Carlyon) said his complaint was that the information in this case was not sufficient or satisfactory, so as to warrant the registering of the death. The jury returned a verdict of "Death from natural causes," and added a rider that medical men should give death certificates on the proper form or not at all. At a meeting of the Redruth board of guardians, held on July 23rd, the clerk, who is also the superintendent registrar, said that the coroner, in reference to death certificates, showed ignorance of the Registrar-General's regulations. He added that Mr. Hichens's letter was a most proper one, and it was clearly the registrar's duty to register the death as uncertified.

Enquirer.—From our correspondent's account we do not think that C can be held to blame. The situation is an annoying one, and we understand that he honestly tried to escape from it. B and C should take care not to allow their professional intercourse to be in the least affected thereby.

Socratine.—There can be no doubt that the owners of the diplomas mentioned are wrong in their assumption of the title of "Dr." unless they have other claims.

F. P. P.—The information has been forwarded to our correspondent.

THE PATHOLOGY OF OPIUM SMOKING.

DR. COLBORNE, writing in the *Phonographic Record*, says, from personal experience in China, that the Chinese can detect an opium smoker by the expression of his face. There are a flattening of the features, a general want of expression, and a look of ill-health, as if the motor nerves of the muscles of the face were more or less permanently interfered with. These or similar nerves would probably be influenced in the same way in thought and the higher cerebral operations, and the altered facial expression probably indicates a deterioration in the action of the higher cerebral nerves generally. From this Dr. Colborne concludes that the evil effects of the habit—the carelessness, shamelessness, and deterioration in public and private actions—are easily explained, and, moreover, that they are due to the absorption of morphia, of which the ill-effects are sufficiently well known. Although this opinion is not corroborated by the conclusions of the Opium Commission, Dr. Colborne contends that the question cannot be considered settled, and that in many opium smokers it is possible to recognise the traces of the habit, just as medical men in England detect the effects of drink upon some patients who consult them.

TUBERCULOSIS AND MEAT.

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly supply me with authoritative information as to the degree of tuberculous disease which should render the carcase of a cow unfit for human food? If one lung was found completely destroyed by the disease, should the whole carcase be condemned and destroyed? The name of any book or article on this subject would be acceptable.—I am, Sirs, yours truly,

July 25th, 1897. M. S.

ERRATUM.—In our appointment column of July 3rd the appointment was announced of T. F. Keenan, M.B., B.S. Durh., as Medical Officer for the Referagh Dispensary District of the Carrickmacross Union. Dr. T. F. Keenan, of Middlesbro', writes to us to point out that he knows nothing of the place or the appointment in question, and we wish to express our sincere regret that such a mistake should have occurred.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (11th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (12th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (14th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (10th).—ROYAL BOTANIC SOCIETY (Regent's Park).—1 P.M. Annual Meeting. Mr. J. S. Rubinstein will bring forward motions recommending the Council (*a*) to Establish Classes in the Gardens for the Study of Botany to be open to all Students; (*b*) to Invite the Royal Horticultural Society to Confer as to the Feasibility of Effecting a Union of the two Societies; (*c*) to Increase the Facilities for the holding of Exhibitions, Garden Parties, or Receptions in the Gardens by Local Authorities and by leading Societies and Institutions.

During the week marked copies of the following newspapers have been received:—*Manchester Guardian, Staffordshire Chronicle, Yorkshire Herald, Brighton Gazette, Jarrow Express, Hull Daily Mail, Bradford Argus, Sheffield Evening Telegraph, Eastern Morning News, Builder, Lincolnshire Echo, Wolverhampton Express, Middlesex Courier, Times of India, New York Herald, Le Figaro, Pioneer Mail, Le Temps, Rangoon Times, Hampshire Telegraph, Leicester Post, South Wales Daily News, Architect, Brighton Argus, Newcastle Journal, Carlisle Express, Liverpool Daily Post, Cumberland Advertiser, Salisbury Journal, Walsall Advertiser, Bristol Mercury, Rushden Echo, Temperance Record, Western Morning News, Leeds Mercury, Kentish Independent, East Anglican Times, Birmingham Gazette, Yorkshire Post, Cork Examiner, Scotsman, Sanitary Record, Local Government Chronicle, City Press, Hertfordshire Mercury, Weekly Free Press and Aberdeen Herald, Reading Mercury, Brighton Gazette, Mining Journal, Surrey Advertiser, Public Health, Guy's Hospital Gazette, Westminster Review, Gazette (Montreal), Manchester City News, Flintshire Observer, Peterborough Express, Sussex Daily News, West Middlesex Herald, Gloucester Journal, Hexham Courant, Kent County Standard, Local Government Journal, &c., &c.*

An Address

Delivered to the Young Officers on Leaving the Army Medical School, Netley, on July 30th, 1897,

BY MAJOR-GENERAL SIR WILLIAM F. BUTLER, K.C.B.

GENTLEMEN,—It would be mere affectation on my part were I to speak to you upon the technicalities of the profession you have chosen, the great gateway of which, if I might so call it, you are now about to enter; the most junior member among you would quickly detect the fact that he knew a thousand times more about the subject than the man who was addressing him, and although there is an adage which says that every man must be either a fool or a physician at forty years of age, I shall not be tempted by the cunning sound of that saying, to betray to your intelligent criticism that in not being one of the alternatives I may possibly be the other; but, gentlemen, the man who has passed forty years of age, and still more the man who has spent nigh forty years in the service, must, if he has not deliberately closed his eyes upon the whole panorama of life, have gathered some impressions of men and of affairs of interest, at least to those younger men who are about to begin their careers, and therefore on this occasion I shall endeavour to put before you some thoughts which have come to me when I considered to myself how I should best respond to the invitation with which the President and Senate of the Army Medical School honoured me when they asked me to present the prizes to the successful candidates for commissions in the army to-day.

And first of all, gentlemen, I would desire to speak of the profession you have chosen. I regard it, in one sense at least, as being the highest of all professions. Without it war would be worse than the savagery of wild animals, and particularly would modern war be that, for every invention of its active brain tends more and more to remove from the battle-field the old ideas of personal prowess, chivalry, and individual effort, and to substitute methods of wholesale slaughter by every means which science can invent. You represent, then, the humanising element in the great profession of arms, which still remains great, not because of newer explosives and more destructive methods, but because the men who practise it are ready to devote their lives to their country, and have old maxims and traditions of duty in their hearts, even though they have new Maxim guns and high explosives in their hands. And you represent also another quality, almost as valuable as that of humanity itself. I would call it openness, or freedom of mind; your studies, your inquiries, your familiarities with the great factors of life, and with the causes which end life, all these go to form independent thought, which in no profession is of greater value than in that of arms, where necessarily the chief mental danger is a too restricted idea of the horizon of life. In saying this I am not merely uttering phrases flattering to your personal vanities, I am telling you what I found to be the case in the experience of my own life, and still more in whatever reading of life I have been able to do. I will take as an illustration of my meaning an event which must be familiar to many among you, and which will probably remain in history as long as history remains in the world. I refer to the captivity of Napoleon in the island of St. Helena. In that record of blind official blundering two names stand out in striking contrast from the timid or time-serving actors of that unhappy drama. Both these bright exceptions belonged to your profession. The first stands immortalised in the poetry of Byron as

> "The stiff surgeon, who maintained his cause,
> Hath lost his case, and gained the world's applause."

I take the action of these two brave and honourable gentlemen at St. Helena to represent exactly what I mean by the phrase "open fearlessness of mind." Undeterred by the weight of official censure, fixed in the immutable traditions of honour, truth, and justice, these two comparatively humble men stood out in protest against the mean and stupid persecution to which the great dying soldier was subjected. They alone protested. It is true they lost everything, but they won more than "the world's applause," for in a measure they redeemed the national honour when the action of their official superiors had compromised it.

I turn to another illustration of what I mean when I quote the name, and allude to the professional career, of the great Surgeon-General of the French army, Baron Larrey. When Napoleon at St. Helena was reviewing the lives of all the illustrious soldiers and officials who had served under him, the one he selected as the typical officer was Larrey. "If the army were to raise a column to the memory of anyone, it should be to that of Larrey," he said; and again in his last will he wrote: "I bequeath to the surgeon in chief of the French army, Baron Larrey, 100,000 francs. He is the most virtuous man I have ever known." What a glorious testimony, and the essence of that virtue was a noble and fearless independence of mind, which made the man always greater than his work, however great that work might be.

Gentlemen, you will excuse me if I introduce a reference personal to myself into these few words of mine to you. Nearly five-and-twenty years ago, I, too, was a candidate at Netley; but it was as a candidate for life. I was brought here a mere wreck of flesh and ruckle of bones from the West Coast of Africa, and if I am to-day addressing you, it is, under Providence, because of the care and sympathy and scientific skill which was bestowed upon me by the men then here, among whom were two at least of the distinguished officers whose names are associated with the prizes I have just presented to you. A few of these distinguished men are still among us, but most of them have joined the majority. Gentlemen, if I recall the recollection of that time, now, it is only to wish you, with the deeper feeling which its memory evokes, a career happy and prosperous to yourselves and useful and honourable to your country.

THE RESULT OF OPERATIONS FOR STRANGULATED HERNIA, AND THE RADICAL CURE OF HERNIA.

BY A. MARMADUKE SHEILD, F.R.C.S. ENG.,
ASSISTANT SURGEON AND LECTURER ON PRACTICAL SURGERY, ST. GEORGE'S HOSPITAL.

IT has often been remarked with truth that more is learned from the publication of unsuccessful than successful cases. We are all too apt to notify our striking successes and conceal our failures. In this paper will be found related all the cases of strangulated and radical cure of hernia that I can find the notes of up to the year 1897. Three cases of strangulated hernia are not reported in full, since the notes are incomplete. They all recovered, and may be taken in the calculation of the mortality. I have performed the operation for radical cure and for strangulated hernia in a few other cases of which no notes have been taken. I can recollect that none of these were fatal, and I have been most careful to include in the tables all unfavourable results and fatalities which are recorded. It is hoped that the account of these cases, though comparatively few in number, may serve as a useful illustration to the subject, and fairly represent the results of modern hernia practice. I feel sure that the true value of the radical cure operation for hernia has yet to be learned, and that largely from the results of private practice, where not only can the patients carry out instructions for treatment essential to success, but the final results after terms of years can be sufficiently estimated.

The method of operation in the strangulated cases may briefly be summarised as follows. The parts are shaved and cleaned with hot water and soap and afterwards with turpentine. They are then sponged with 1 in 20 carbolic lotion, and a compress of the same solution is laid upon the site of operation until the operation is proceeded with. In my later cases I have used also perchloride of mercury solution (1 in 1000). A moderate attempt at the taxis is always made, unless serious damage to the gut is suspected. The penis in all cases is wrapped in iodoform gauze. As few instruments are employed as possible. The patient is warmly clad, especially as to the feet and legs. The anæsthetic has generally been chloroform or the A.C.E.

Digitized by Google

mixture. Ether has been avoided because of its tendency to cause bronchial catarrh, especially in predisposed or elderly people. The anæsthetic has been lightly given, and the head kept on the side, and I have always urged on the anæsthetist, when not experienced, the importance of carefully watching for, and dealing with, those violent attacks of regurgitant vomiting, which are so sudden, common, and dangerous during the anæsthetic state in all forms of intestinal obstruction. In two bad cases the stomach was washed out before operation with warm water. In performing the operation speed has always been aimed at, and no needless time was wasted in separating the various layers of tissue over the sac with a director. The radical cure has been done at the same time, in all cases unless the patient is seriously ill and collapsed or very aged, when the sac has been merely disinfected by swabbing with strong carbolic acid lotion and has been cut away, the operation being completed with all possible celerity. The sac and ring sutures have been kangaroo tendon in the earlier cases and boiled silk in the later. The skin sutures have been silkworm gut and horsehair. Drainage for six hours has only been adopted in those cases where the operation was extensive, as in cases of large ruptures. The after-treatment of the strangulated and severe radical cure cases consists of nutrient enemata every three hours by the bowel and small quantities of warm water by the mouth for the first six hours, fluid nourishment being gradually given by the mouth according to the severity of the case. Thirst has been relieved by enemata of milk and warm water. Any signs of abdominal distension or distress after the first two days have been treated by the administration of saline aperients, the sulphates of soda, and magnesia with carminatives, and this has been aided by enemata containing turpentine or oil of rue.[1] The action of the bowels has always relieved the symptoms in a remarkable manner, and I am as certain as I can be of any clinical fact that this practice, which it is right and proper to acknowledge I have learned from the teachings of Mr. Lawson Tait, has in my hands saved several lives. In the after-treatment of cases of "radical cure" I have aimed at complete rest for a month and partial rest with slight exercise for another month. In hospital practice this is difficult to ensure, and neglect of rest is one of the causes of failure.

As regards the operations for radical cure apart from strangulation I have always aimed at rigid asepsis. This is especially needful in young children, in whom these wounds are apt to suppurate—at all events, superficially—unless great care be taken in this respect. The method of operation has generally been to place the incision high up away from the scrotum. This important modification, as important in strangulated cases as those we are considering, has a twofold advantage: (1) it enables the operator to separate readily the sac from the cord; and (2) it is remote from sources of septic influences. In strangulated cases it brings the operator close to the site of stricture, and enables him to deal with it more quickly than when the finger is thrust some distance up the canal. Attention was first forcibly drawn to this important detail by Mr. Lockwood. The patients have been prepared beforehand by purgation and enemata, and in cases of large irreducible herniæ all attempts have been made by purgation and position with pressure to lessen the bulk of the rupture or effect its reduction before operation. In most cases complete reduction has been impossible on account of adherent omentum. I have paid special attention to isolating and drawing down the sac and ligaturing it as "flush" with the internal ring as possible. Torsion of the sac has usually been performed. The walls of the canal have been drawn together closely by a succession of sutures passed so as to aim at drawing the transversalis aponeurosis and conjoined tendon to Poupart's ligament and the external oblique. Macewen's method has been adopted in passing the sutures. In some very bad cases, where the opening into the abdomen has been direct and large enough to admit three or four fingers, I have simply closed it as one would do an abdominal section, sewing the peritoneum and muscles deliberately together with fine silk, and this I think is by far the best course to adopt. In removal of omentum small pieces have been transfixed and tied with the ordinary safety knot. Large portions have been tied in small sections, the vessel being "teased" out of the fat until quite distinct. I have found this better than tying the omentum in a large mass. Ligature of omentum is a dangerous proceeding and should be conducted with the most scrupulous care, or intra-peritoneal bleeding will certainly occur.

In one case of operation upon an enormous irreducible hernia containing much intestine there were found almost insuperable difficulties in returning the intestine. On this occasion I opened and drained the intestine. This simple procedure aided me greatly, and alone made the return of the intestine possible. A small puncture is made with a tenotome in a prominent coil of bowel, and the contents of that and neighbouring coils squeezed out by a gentle process of "milking." The puncture being washed and cleansed is next united by a fine Czerny-Lembert suture. The operation does not take long, and does far less harm to the bowel than the prolonged squeezing, kneading, and pushing, cracking the peritoneal coat, which one is apt to witness in these very perplexing cases.[2] In all my later cases I have used boiled silk for ligaturing the sac and uniting the canal. I have had remarkably few cases of "stitch suppuration." I believe the common cause of this undesirable condition is neglect to boil the needles and sutures. In children I have never employed drainage. The wound when closed is varnished over with collodion and iodoform. A gauze dressing is then applied, and over that some wool. Very firm pressure is exercised on the site of operation. The dressings are covered with protective sheeting and varnished. The penis is brought well out through the dressings, and in some cases one has been able to adjust a test-tube, so that the bulk of the urine trickles into it. I attribute the excellent recoveries generally observed in my cases at the Royal Hospital for Children and Women, Waterloo-road, to the care taken in the after-treatment by the house surgeons and nurses of that institution. I have been very particular to keep the child dry and clean, and to see that the skin of the perineum is well cleansed, and a pad of iodoform wool has always been laid there in the dressing. In all the cases where large masses of omentum have been removed some "unpleasant" abdominal symptoms have generally appeared, as severe pain, and especially a tendency to distension of the abdomen, with hiccough or sickness. In Case 24 this was markedly observed. On the fourth day this patient's condition was such as to cause anxiety regarding some obscure internal strangulation, yet under saline purgatives and copious enemata he made an easy recovery, his symptoms absolutely disappearing with the first copious action of the bowels.

So far as I am able to judge regarding the results of operations for the radical cure of hernia it amounts to this. If a surgeon were to select his cases, choosing small ruptures, with a long oblique canal, in young patients who were able long to rest and to avoid laborious occupations after, the percentages of absolute cures would be very high. If, on the contrary, he operates upon all cases as they come under his notice—a practice which is perhaps hardly wise or judicious—he will have a number of relapses, a number only able to wear a truss, and a smaller percentage of genuine cures. I have refused to operate upon several cases where the hernia seemed to be very direct, coming straight out through an opening readily to be appreciated by the finger, and in those whose abdominal walls are weak and lax. The risks of the operation for strangulated hernia vary directly with the severity of the case. With asepsis and rapid operating the mortality in early cases of strangulation should now be exceedingly small. Taking all cases as they come, including some cases in old and feeble people, the mortality exemplified in my tables is, I should think, fairly representative of modern practice.

During the present year, 1897, I have operated upon three successive cases of irreducible hernia, where a "tag" of omentum was firmly adherent to the sac. In two of these money, time, and ingenuity had been fruitlessly expended in trusses, which rather aggravated the symptoms. Mr. W. Haward has read an excellent paper this year upon the importance of adherent omentum,[3] and this condition is one which generally calls for operation when other means of reduction fail.

[1] The old "enema rutæ" has long been used at St. George's Hospital for cases of obstruction with flatulence. It is composed as follows: three drachms of confection of rue and sixteen ounces of infusion of camomile. The warm infusion is poured upon the confection and the two substances are intimately mixed. The enema is administered warm. This valuable remedy deserves more extensive use.

[2] The return of intestine is greatly facilitated by raising the foot of the table considerably, until the intestines gravitate towards the diaphragm. In private houses this can be accomplished by placing blocks of wood or small casks under the feet of the bed or table.

TABLE I.—*Cases of Strangulated Hernia.*

No. of Case.	Sex.	Age.	Nature of case and date of operation.	Operation.	After-complications.	Result.
1	M.	30	Left inguinal hernia as long as he could remember. Had never worn a truss. Acute symptoms of strangulation present for two days. (July 8th, 1892.)	Gut found very black and congested. After division of the stricture and reduction, the sac was well washed out with strong carbolic lotion and cut away. Stump of sac twisted and tied high up with boiled silk. Pillars of ring sewn together with same.	None.	Recovered. Left hospital on July 15th at his own request. The wound was securely healed, with a strong cicatrix. Heard four years after that he had had no return of rupture.
2	M.	61	The patient was very stout and bronchitic. Right femoral hernia; had been tightly strangulated for four days before operation. Symptoms unfortunately overlooked. He was collapsed, with cold extremities and pulse hardly to be felt at wrist. (July, 1880.)	Usual operation. Chloroform administered. Gut proved gangrenous. Offensive black fluid in sac.	—	Died before completion of operation: he seemed moribund at its commencement.
3	F.	65	Right femoral hernia, tightly strangulated for twenty-four hours. Very collapsed at time of operation. (March, 1892.)	Chloroform administered. Operation done as rapidly as possible. Gut very black and congested. No attempt at radical cure beyond ligature of sac.	None. Bowels opened by salines and enemata on fourth day.	Recovered.
4	F.	70	Right femoral hernia. Strangulated for twelve hours. (February, 1891.)	Chloroform administered. Operation done as quickly as possible. No attempt at radical cure beyond ligature of sac.	Serious abdominal distension on fourth day, relieved by sulphates and enemata.	Recovered. This patient has since died from influenza She wore a truss comfortably after the operation.
5	F.	59	Right femoral hernia. Strangulated for sixteen hours. Symptoms very acute. (March, 1891.)	Chloroform administered. Operation done speedily. No attempt at radical cure beyond ligature of sac.	None.	Recovered. Well in 1894; wearing a truss, but no sign of hernia.
6	M.	63	Strangulated right inguinal hernia. (Jan. 22nd, 1894.)	Gut deeply congested; claret-coloured fluid in sac. Radical cure performed.	Bronchitis at the time of operation.	Died next day, very collapsed and cyanosed.
7	M.	17	Right inguinal hernia strangulated acutely. Rupture had only existed for one day. (Jan. 21st, 1894.)	Radical cure performed as well as operation for strangulation.	None.	Recovered: discharged with truss on Feb. 19th, 1894. Writes to say he is quite well one year and ten months after, and is able to do labourer's work.
8	F.	49	Strangulated left femoral hernia existing twelve months. Never worn a truss. (April 14th, 1894.)	Gut deep plum-coloured. No radical cure on account of serious state of patient, excepting ligature and excision of sac.	None.	Recovered: writes two years after that she is well, and with a truss finds no return of rupture.
9	M.	63	Strangulated left femoral hernia for five days. Taxis applied violently outside hospital. Condition apparently desperate. (Sept. 8th, 1894.)	Operation; sac contained intestine on the "verge of gangrene" and claret-coloured fluid. No radical cure.	None, beyond serious collapse combated by nutrient enemata containing brandy. Stitch suppuration at one spot.	Recovered: insisted on leaving on Sept. 23rd, 1894, when the wound was not quite healed.
10	M.	36	Strangulated internal hernia; also had an irreducible right scrotal omental hernia, which added to the difficulties of case. (Sept. 22nd, 1894.)	This case should rather be classed with abdominal section. A coil of deeply-congested gut found strangulated in the mesentery. The diagnosis of this case was quite obscure. Omental hernia left alone.	None.	Recovered. Discharged with abdominal belt, Nov. 10th. writes a year after that he is "quite well." Omental hernia still irreducible.
11	M.	46	Strangulated right inguinal hernia. (Aug. 24th, 1895.)	Radical cure performed as well as operation for strangulation.	Day after operation free bleeding occurred from the wound which was opened up, and clots turned out. No source of bleeding could be found.	Died on Aug. 26th, quite suddenly. There was no certain cause for his death discovered.
12	M.	31	Strangulated right inguinal hernia of large size and long irreducible. (Sept. 9th, 1895.)	Radical cure as well as operation for strangulation. The hernia contained the cæcum. There was no proper sac. Dense adhesions everywhere present. Incision had to be prolonged upwards before gut could be reduced. Considerable portions of fascia left adherent to gut. Operation very prolonged and difficult.	Slight suppuration round one suture.	Recovered. Discharged with sound cicatrix and truss, Oct. 30th, 1895. Writes one year after to say, "The operation is a success." So large is the cicatrix, however, that I should regard this man as being unfit for laborious work.
13	M.	About 40	Left strangulated inguinal hernia. Long previously irreducible. Symptoms very acute. (July 11th, 1896.)	Radical cure as well as operation for strangulation performed. After division of stricture a tight internal peritoneal band was discovered with the finger, pulled down, and divided.	None.	On his discharge six weeks after there was an excellent firm cicatrix. No impulse on coughing; he was given a truss and advised to rest further.
14	F.	75	The patient was feeble and collapsed; with a strangulated right femoral hernia; history quite unreliable. (Date omitted in notes.)	Sac contained deeply congested gut and claret-coloured fluid. No radical cure performed. Operation completed as speedily as possible.	None beyond collapse, treated by nutrient enemata and stimulants.	Recovered; discharged in a month with firm cicatrix.
15	F.	63	Strangulated left femoral hernia. The patient was feeble and collapsed. (June 15th, 1896.)	Sac contained deeply congested gut and omentum. Sac tied and removed. She had been previously operated upon for strangulation in 1889.	Serious collapse; a mild attack of rambling delirium which lasted for two weeks.	Recovered; discharged with good cicatrix on July 31st.

TABLE II.—*Cases of Radical Cure of Hernia.*

No. of case.	Sex.	Age.	Nature of case and date of operation.	Details of operation, if any.	After-complications, if any.	Final result so far as known.
16	M.	19	Double inguinal hernia all his life. Requested radical cure on account of inability to do any work. (Charing-cross Hospital, May 14th, 1889.)	Both herniæ operated upon. Sac tied with catgut. Pillars of ring and canal sutured together with catgut.	Some fever and pain locally. Recovery delayed by a slight pneumonic attack. Wounds soundly healed by June 4th. No suppuration except round one stitch.	Recovered. On leaving hospital the cicatrices were sound and there was no sign of return. Last heard of three months after discharge, in good condition.
17	M.	27	A large irreducible scrotal swelling on right side. He had suffered from it for five years. Swelling quite incapacitated him on account of its size. (Charing-cross Hospital, Aug. 26th, 1890.)	At operation the whole of transverse colon found in hernia. Large mass of omentum (6 oz.) found adherent. Ligatured in portions and removed. Opening into abdomen would admit three fingers. Sewn together with catgut and boiled silk sutures. Operation prolonged and difficult.	No after-symptoms of importance. Patient left the hospital on Sept. 30th with wound healed. No suppuration except round a superficial suture.	Recovered. Seen four years after operation. No trace of return of hernia. Does not wear a truss.
18	M.	25	Right inguinal hernia and retained testis. Had suffered from boyhood. (Charing-cross Hospital, Sept. 10th, 1891.)	Testis removed. Sac tied with boiled silk sutures high up. Pillars of ring and canal brought together.	Some pain and slight fever for first day. Discharged with wound healed on Sept. 27th. No suppuration.	Recovered. Cicatrix firm when he left hospital six weeks after operation. Not since heard of.
19	M.	21	Right scrotal swelling. Congenital hydrocele, containing gut and a piece of omentum. (Charing-cross Hospital, Feb. 9th, 1891.)	Radical cure performed in usual way. A tongue-shaped piece of omentum found in the sac of a congenital hydrocele.	No after-symptoms of importance. Left hospital on March 17th.	Recovered. Present state not known. Had a firm scar.
20	M.	1½	Inguinal hernia; side not mentioned. (Charing-cross Hospital, Aug. 25th, 1887.)	Radical cure.	Wound healed by first intention. No suppuration.	Recovered. Present state not known. Had a firm scar.
21	M.	15	Left inguinal hernia of twelve months' duration and of large size. (Charing-cross Hospital, March, 1893.)	Radical cure.	None. No suppuration.	Recovered. Left hospital on April 20th. A right inguinal hernia appeared within six months of operation. He did not wear a truss on the side of operation. All went well for three years, when, on making a sudden violent exertion without a truss, the left hernia suddenly came down again. Re-operated upon 1897; at present has a firm cicatrix and wears a truss.
22	M.	15	Left inguinal hernia. Had only been noticed for six weeks; the result of a strain. (Charing-cross Hospital, April 6th, 1893.)	Radical cure. Boiled silk used to tie the sac, and to suture the canal.	None.	Recovered. Discharged with sound cicatrix on April 21st, with instructions to rest.
23	M.	21	Left inguinal hernia all his life. Had attained to size of a cocoa-nut. Trusses kept it up imperfectly. Main part irreducible. (Charing-cross Hospital, Jan. 5th, 1894.)	Radical cure. Hernia first reduced by purgation, elevation of bed, and pressure. Boiled silk employed.	Slight pain and fever. Temperature rose to 100° F. Suppuration round one suture.	Recovered. Wound soundly healed on Jan. 25th, 1894. Good cicatrix.
24	M.	22	Right inguinal hernia since age of eleven years. Retained testis on left side. Trusses always failed to keep up gut. Hernia had been irreducible for nearly twelve months. (Dec. 6th, 1893.)	Radical cure. Hernia congenital and adhesion of coil of ileum to sac. Large mass of adherent omentum ligatured in portions and cut away; weighed 4½ oz. Boiled silk sutures employed to tie sac and suture canal. The patient was kept recumbent two months.	All well until the third day, when he began to suffer from severe abdominal pain and vomited urgently. Large doses of salines given by mouth. Copious enemata. Complete relief after evacuation of flatus.	Recovered. Three years afterwards no sign of return of hernia. Hunts, and leads an active life, without a truss.
25	M.	18	Right inguinal hernia, congenital. Adherent omentum. Had trusses without avail. One attack of strangulation during sea-sickness. (Nov. 1894.)	Radical cure. Adherent omentum removed. Boiled silk sutures employed. Kept recumbent two months.	None.	Recovered. Nearly two years afterwards no sign of return of hernia. Wears a truss as a precautionary measure.
26	M.	4	Congenital right inguinal hernia of large size. No trusses efficacious. (Operation, 1893.)	Radical cure. Very large opening almost directly into abdomen. Sutured with a succession of boiled silk ligatures. Sac contained large intestine. Circumcision also performed.	None. Kept for two months recumbent.	Recovered. Condition three years after: no return of the hernia; wears a truss with a large flat pad as a precautionary measure.
27	M.	18	Right inguinal hernia. Time of duration not stated. (Aug. 28th, 1894.)	No remarks made on operation. It consisted in ligature of the sac and closure of the canal.	None.	Recovered. Discharged to Convalescent hospital, Sept. 24th, 1894. Cicatrix firm. No further report.
28	M.	18	Right inguinal hernia and hydrocele of cord. (Dec. 15th, 1894.)	Radical cure in the usual way; the sac in this case contained an extraordinarily long vermiform appendix, which was removed.	None.	Recovered. Discharged Jan. 23rd, 1895. Seen two years and six months after operation. No return of hernia. Firm cicatrix. Lifted heavy weights and led a laborious life.
29	M.	19	Right inguinal hernia. (May 3rd, 1895.)	Radical cure. No remarks.	None.	Recovered. Discharged June 12th, 1895. Seen one year and three months after. Hernia had partially returned. Result unsatisfactory. Truss now worn.

TABLE II.—*Cases of Radical Cure of Hernia (continued).*

No. of case.	Sex.	Age.	Nature of case and date of operation.	Details of operation, if any.	After-complications, if any.	Final result as far as known.
30	M.	33	Operation for left bubonocele. (Aug. 7th, 1896.)	Radical cure. Sac not certainly defined. Rings and canal closed.	None.	Recovered. Discharged Aug. 24th to rest at Wimbledon. Wrote a year after to say no return, but still wore truss.
31	M.	40	Large, irreducible, scrotal hernia (side not mentioned). (In autumn of 1895.)	Radical cure. Mass of adherent omentum excised. Very large ring united by a succession of deeply placed sutures of kangaroo tendon. The cæcum was found in this case, and was universally adherent. There was no distinct sac. It was only by the greatest difficulty that the gut was finally returned, with large pieces of fascia adherent to it.	None.	Recovered. Discharged, wearing truss, on Nov. 14th, 1895. Wrote twelve months afterwards that rupture was perfectly cured, but he was cautious and still wore truss.
32	M.	59	Enormous right scrotal hernia of many years' duration. Long irreducible. Penis buried in swelling. Had had one attack of obstruction. (Aug. 1st, 1895.)	Radical cure. Sac contained cæcum and greater part of colon, some small intestine, and large masses of adherent omentum. Omentum ligatured and removed. Intestines could not be returned. Coil of colon opened and drained. Opening closed by Lembert suture. Intestines then readily returned. Large ring closed by direct suturing with boiled silk sutures.	None.	Recovered. Discharged on Oct. 2nd, 1895. Had a large cicatrix, and was furnished with a powerful truss with a large, flat pad. Operation merely palliative, and in this respect most successful. Man never again fit for laborious work.
33	M.	44	Large scrotal hernia which has long existed and could not be kept up by any truss (side not mentioned). (Nov. 28th, 1895.)	Radical cure. No remarks.	None.	Recovered. Discharged Dec. 24th, 1895. Wrote ten months afterwards: "I have no return of the rupture and work very hard. The result of the operation is that I am all right."
34	M.	1	Right inguinal hernia. (Oct. 31st, 1893.)	Radical cure. Large sac strongly twisted.	Sloughing of stump of sac; ultimate suppuration and sepsis.	Died from septic pneumonia. An error in the asepticity of operation.
35	M.	2	Large right inguinal hernia, which could not be kept up by any truss.	Radical cure.	None.	Recovered. Seen two years and two months after operation. Firm cicatrix. No return.
36	M.	3	Large left inguinal hernia. Trusses useless.	Radical cure.	None.	Recovered. Seen three months after, with a firm cicatrix and no return. Present state not known.
37	M.	4	Large left inguinal hernia. (Dec. 31st, 1894.)	Radical cure.	None.	Recovered. Ten months after the patient was well, with no sign of return.
38	M.	1½	Immense right inguinal hernia, which no truss could keep up; large intestine in sac. (August, 1895.)	Radical cure; opening into abdomen, which would admit three fingers, sewn together with fine boiled silk.	None.	Recovered. Discharged wearing a truss with large flat pad, which was discontinued by parents. A year after operation, while screaming in a fit of rage, the hernia suddenly came down, and he was brought to see me. The rupture was readily reducible, and a truss could keep it up, but the result of the operation was a failure.
39	M.	1½	Left inguinal hernia. (Oct. 14th, 1896).	Radical cure.	None.	Recovered. Seven months after operation no return of rupture.
40	M.	1⅔	Very large, left inguinal hernia. (February, 1896.)	Radical cure.	None.	Recovered. Seven months after, firm cicatrix, no return, wore truss as a precautionary measure.
41	M.	1⅞	Very large right scrotal hernia. (March, 1896.)	Radical cure.	None.	Recovered. In August, 1896, the patient's condition was excellent, but he did not wear a truss and the cicatrix was quite uncared for.
42	M.	4½	Very large right inguinal hernia. (April, 1896.)	Radical cure.	None.	Recovered. Firm cicatrix: well without return five months afterwards.
43	M.	1	Very large hernia. Ring admitted three fingers. (May, 1896.)	Radical cure.	None.	Recovered. Result excellent two months after operation.
44	M.	3	Right inguinal hernia. Ring admitted two fingers. (July 6th, 1896.)	Radical cure.	None.	Recovered. Result excellent; no return so far as is known.
45	M.	2	Left inguinal hernia.	Radical cure.	None.	Recovered. Result good; no return so far as is known.
46	M.	1½	Right inguinal hernia. (Aug. 24th, 1896.)	Radical cure.	None.	Recovered. Result appeared to be excellent.

Statistics in hernia cases are most misleading. For instance, a surgeon may operate upon twenty patients with strangulated hernia without a death if he gets early cases in vigorous subjects. His next series may comprise many instances of neglected strangulation in old and feeble individuals, when his mortality will be as great as his previous success was notable. I believe by rapid operating and great care in anæsthesia the mortality even in bad hernia cases is very much diminished. If the truth were told it would be even now very high, and this has led Mr. Hutchinson to advocate strongly the persevering employment of the taxis before resorting to operation. This important point I cannot attempt to discuss in this article. Undoubtedly much will depend upon the asepticity and experience of the operator, the celerity with which the operation is performed, and the skill and care of the anæsthetist. In old and feeble folk the reduction by taxis, if this can possibly be brought about, is probably less dangerous than operation. In vigorous subjects the same remark does not apply.

The results of operations for radical cure of hernia can hardly be judged fairly from hospital experience. Too often the patients, especially adults, as soon as they are discharged return to laborious occupations, such as lifting great weights, which no operation barrier, however well constructed, could possibly certainly resist. Several of my operations have, however, resisted every effort on the part of the patient to reproduce his hernia, and these truly termed "test cases" may fairly be opposed to the failures. It is absurd to suppose that any operation can be devised by the wit of man which could certainly prevent the return of rupture in a patient who exposes himself to laborious, heavy work, involving strain of the abdominal muscles.

Taking first the cases of strangulated hernia, amounting with the three unrecorded cases to eighteen, I may remark that I have treated a considerable number of strangulated herniæ by taxis, and have thus, perhaps, performed fewer operations than I might otherwise readily have obtained. The mortality is three in eighteen, or about 15 per cent. Of the fatal cases it will be noticed that Case 2 typically illustrates the hopeless sort of strangulated hernia that we are obliged to operate upon with a faint hope of saving life and with a great probability of swelling our mortality statistics. This case is interesting to compare with Case 9, a feeble old man apparently dying, yet who made a perfect recovery. The latter case illustrates how one may sometimes save an apparently moribund patient. Case 6 died from bronchitis, and though I cannot certainly recollect I believe ether was used as the anæsthetic. Operations upon bronchitic old patients in cold weather suffering from hernia or intestinal obstruction of any sort are peculiarly dangerous. Case 11 is a very instructive one, and the disastrous result is plainly due to an error in operation—i.e., leaving undetected and insecure a bleeding vessel. Those who are unaccustomed to operate in these regions scarcely appreciate how important it is to secure every bleeding point. This is particularly the case when the incision implicates the scrotal tissues. In such operations as radical cure of hydrocele or sarcocele too much care can hardly be taken in this important and sometimes difficult matter. This is the only instance in all my cases of any trouble occurring with hæmorrhage. Being fully alive to its possibility I have taken peculiar pains to secure all bleeding points, and the occurrence of the mishap in this case only shows how "reactionary bleeding" may take place in incisions affecting the scrotum and inguinal canal, even in the practice of those aware of the danger and anxious by care to obviate its occurrence. It is worthy of remark that the only "opiate" given in the after treatment was small doses of laudanum (five minims) in the nutrient enemata for the first twenty-four hours. Any signs of abdominal distension on the third or fourth day were always met by saline purgatives and copious enemata. No case of gangrene of the gut presented itself.

The cases of radical cure uncomplicated by strangulation are thirty-one in number. Of these one died plainly from sepsis (No. 34). A mortality of about 3 per cent. is higher than should occur in these cases. If, however, surgeons undertake the cases when the operation is especially beneficial—i.e., in large irreducible herniæ with adherent omentum—they will be fortunate if they can show a smaller mortality. By careful selection of cases, and refusing those which seem risky, any surgeon well versed in care and cleanliness might easily reduce this mortality to "nothing" per cent. Many of the cases in children were severe, and such cases as Nos. 17, 24, and 32 may well be referred to as involving especial operative risk.

Of the strangulated cases in which radical cure was performed two died. The operation for radical cure had nothing to do with the fatal result. The four remaining strangulated cases in which radical cure was performed may be added to the thirty-one uncomplicated cases of radical cure for an estimation of the results. In the thirty-five cases thus compiled only three relapses have been traced. The results of each operation are given as far as known. It is, of course, quite possible that relapses have taken place in some of the cases lost sight of, though great care was taken to impress upon each patient that he was to show himself if this occurred. The recorded results are on the whole satisfactory, especially as some of the patients were engaged in most laborious work, and all those of the hospital class had quite ignored the precautions impressed upon them.

The cases of umbilical hernia must be separately considered. They number seven; of these, four were fatal and three recovered. The causes of death in the fatal cases were as follows: in two the sac had sloughed prior to operation; these were quite hopeless. In one the patient sank from exhaustion, being old, extremely obese, with fatty degeneration of the viscera. In one capillary bronchitis was the cause of the fatal termination. Ether was administered in this case. Of the three cases of recovery, one was a comparatively small rupture, mainly containing omentum. The two remaining were large and formidable, apparently containing the bulk of the intestine, and the method of operation adopted is worth notice. The large rupture being raised, a vertical incision about two and a half inches in length was made in the middle line, opening the hernial sac at its neck, dividing the fibrous ring of the hernial orifice and the linea alba. The finger being then introduced among the complex contents of the rupture, any fine "snare-like" bands that could be felt were pulled upon until they gave way. In one of these cases it was possible to draw bands into sight, when they were divided between double ligatures. The mass being then kneaded, gurgling was appreciated, and some of the intestine returned towards what was left of an abdominal cavity. The incision was carefully closed, and copious enemata were administered, the bowels soon acting freely. This method is, of course, open to the objection of uncertainty, but free from the anxieties and perils which beset the practice of freely opening a huge umbilical hernia containing most of the abdominal contents in a feeble old person. It is right for me to acknowledge that this operation, which may possibly be of advantage to surgeons who have to undertake these desperate cases away from skilled assistance, I first saw performed by the late Sir George Humphry. It would not be applicable to cases where ulceration of the gut at the margin of the ring might be suspected from long continuance of the symptoms.

In conclusion, I must thank Miss Jacobi, the registrar at the Royal Hospital for Children and Women, Waterloo-road; Mr. Lockyer, of Charing-cross Hospital; and Mr. Cooper, of St. George's Hospital, for the trouble they have taken in assisting me to look up the notes of these cases.

Cavendish-place, W.

ON THE USE OF ALCOHOLIC BEVERAGES IN RHEUMATIC AND GOUTY CONDITIONS.

BY T. DIXON SAVILL, M.D., M.R.C.P. LOND.,

PHYSICIAN TO THE WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM; EXAMINER IN MEDICINE IN THE UNIVERSITY OF GLASGOW; FORMERLY MEDICAL SUPERINTENDENT TO THE PADDINGTON INFIRMARY.

THE late Dr. George Harley,[1] shortly before his death, advocated—or at any rate sanctioned—the drinking of sweet champagnes by gouty persons. Any statement on gout coming from so high an authority deserves our most careful consideration; but as it is directly at variance with the views generally held and the whole of my own experience, I feel bound, though with much deference and with greater detail than would otherwise be necessary, to enter my protest. It may be noticed, in passing, that the only case he quoted

[1] THE LANCET, July 4th and Aug. 1st, 1896.

Digitized by Google

was his own, and the seven arguments which he mentioned on page 309 are examples of the fact that sugar alone taken by healthy persons will not produce gout. From these facts it is inferred that sweet wines may be taken by the gouty with impunity. Now, it is quite conceivable—and I shall mention facts supporting the idea—that although syrupy non-alcoholic beverages may be taken by healthy and even by gouty persons without evil effects, excepting for the dyspepsia they may produce when taken in large quantity, nevertheless, sweet alcoholic beverages may do a considerable amount of harm; although Dr. Thorowgood, also a high authority on this question, who wrote to THE LANCET[2] protesting against Dr. Harley's statement, quotes the case of a very gouty patient who "found that sugar in any form was eminently provocative of an attack," and, adds Dr. Thorowgood, "his experience is by no means singular."

Nothing is commoner in every-day practice than to be called upon to decide whether alcoholic stimulants are permissible in rheumatic and gouty conditions, and in healthy persons having an inherited tendency to these diseases, and if so, what is the form in which they can best be administered. It is the object of this communication to adduce certain facts which go to show, first, that pure ethylic alcohol does very little harm *per se* in such cases, especially if taken at meal times only and in a dilute form; secondly, that the most detrimental component of ordinary alcoholic beverages is the sugar they contain—i.e., that a sweet alcoholic beverage does harm; thirdly, that when certain wines and beers are deprived of their sugar they may be taken with impunity even by those who have gouty and rheumatic tendencies; and fourthly, my experience goes even farther than this, for I find that there are certain cases belonging to the uric acid group—like the two cases of migraine mentioned below—where stimulants judiciously administered actually do good, and that there are certain other cases where some concurrent condition, such as cardiac failure, urgently calls for the use of alcohol, in either of which circumstances it becomes a question of considerable importance how best to administer it. It is hardly necessary to enumerate all the many and various manifestations of these extremely common disorders; suffice it to say that the remarks which follow refer to the various muscular, fascial, and arthritic manifestations of rheumatism, gout, and lithæmia (or, as some prefer to call it, uric-acid-æmia). The symptoms of the latter include headache, lassitude, general stiffness, depression of spirits, incapacity for mental and bodily exertion, and several other familiar symptoms. It is neither necessary nor desirable for our present purpose to enter into a discussion of the pathology of these various conditions, for it is now very generally admitted that uric acid, either free or in combination, is at the bottom of them all. Perhaps I may be pardoned for mentioning at the outset that a unique opportunity for the observation of these complaints has fallen to my lot, because not only for seven years at the Paddington Infirmary did I have under my care many hundred unselected (the converse of hospital practice) examples of their many varieties, but for nearly eighteen years I have myself been a martyr on and off to one or another of nearly every kind of chronic rheumatism known—arthritic, muscular, and fascial.

The principal ingredients of every alcoholic beverage come under one of three headings, as shown in the table below—namely, alcohol, sugary substances, and acidity (i.e., free acid or acid salts); and the proportion of these different ingredients varies very widely in spirits, wines, and beers. Special attention is called to the right-hand column of each constituent, where the ordinary dose or potion of each is given and the actual quantity of alcohol, sugar, and acidity thus imbibed is worked out. Now in every-day life the potion of wine, beer, or spirit is regulated by the amount of alcohol it contains, but by this table the extraordinary difference in the amount of sugary substances and the less marked difference in the acid substances imbibed at the same time is brought out in full relief. Considerable variety of opinion still exists as to which of the three constituents it is that does the harm. Old writers used to pay special regard to the alcohol; then came the sugar crusade; and finally in modern times observers, among whom Dr. Alexander Haig[3] may be mentioned, regard the acidity as quite sufficient to account for all the harmful consequences which arise. Dr. Harley apparently regarded the acidity and the alcohol as the most detrimental constituents.[4]

[2] THE LANCET, July 11th, 1896.

[3] On Uric Acid, third edition.

[4] Loc. cit., p. 15.

An inspection of this table shows that an ordinary dose or potion of spirit, wine, or beer contains approximately the same amount of alcohol, but differs very widely in other respects. Thus, 1 oz. of spirit, such as brandy or whisky (which is perhaps rather smaller than the usual dose), contains little or no sugar, and at the most only the equivalent of one grain of acidity; a wine-glass of port wine (which usually holds 2½ oz.) contains about 50 grs. of sugar, and the equivalent of about 5 grs. of acidity; a glass of sherry 20 grs. of sugar and 7½ grs. of acidity; a glass of claret (holding, say, 4 oz.) from 4 to 8 grs. of sugar, and 8 grs. of acid substances; a glass of hock (containing 4 oz.) varies somewhat as to sugar, but contains about 12 grs. of acid substances; a half-pint of ale contains from 200 to 400 grs. of sugar, and about 10 to 15 grs. of free or loosely combined acids. Represented in this way, the differences in composition are very striking, and much in their relative actions which is otherwise inexplicable becomes intelligible. It will be observed that whereas a relatively small difference exists in the amount of acidity contained in a potion of light wine and in one of beer, the differences in the amount of sugar are very great. Objection may be taken to such a table that it takes no account of the various ethers, tannin, colouring matters, and the various other constituents of what chemists call extractives; but in reply it may be urged that these never exist in large quantity, are none of them very constant, and that they do not materially affect the issue of the question under consideration.

1. *Personal experience.*—Ever since a severe attack of acute rheumatism in 1879 I have been liable to the various manifestations of that disorder in an acute or chronic form unless I take the greatest care in the adjustment of my dietary. As regards stimulants my experience is that pure alcohol, such as pure spirit matured by age in the wood, taken in small quantities well diluted and with meals only, has never aggravated the rheumatic symptoms either at the time or subsequently. On the other hand, alcoholic beverages did harm precisely in proportion to the amount of sugar they contain. For example, port wine and Madeira were bad, but beer was far worse than any. A single glass of any kind of beer (and very many different samples have been tried), although taken at meal times, invariably exacts the most severe penalties, and if persevered in always results in the joints becoming painful (often swollen also) and stiff; or, if they were already affected, they became worse. A glass of port wine produces the same effects, though usually in a less degree, and lasting for a shorter time. Non-alcoholic syrups, if taken occasionally, do not affect me at all in the same way. My principal beverage for many years has consisted chiefly of home-made lemonade;[5] and in summer time "lemon squash," lime juice cordial, occasionally raspberry, and other teetotal syrups. These sugary drinks never increase my rheumatic infirmities unless they are taken sufficiently long and in sufficient quantity to produce dyspepsia.

2. *Infirmary cases.*—It is unnecessary to refer in detail to the numerous cases of gouty and rheumatic affections and lithæmia which were under my care at different times, and in such endless variety, at the Paddington Infirmary. Instead of the cheap inferior brandy usually supplied in these institutions I induced my board to supply the patients with a high-class old Scotch whisky costing in bulk no more than bad brandy; and my choice rested (in those cases which called for alcohol) between this pure whisky without sugar, sweet port wine, and an ordinary beer such as the analysis given above. The invariable result showed, on the one hand, that the whisky never aggravated the gouty or rheumatic symptoms, but, on the other hand, they were always increased directly the patient was put on port wine or beer. The male patients were, of course, very anxious to have beer in preference to anything else, and would often try to hide their symptoms, but the stiffness of their walk, sometimes the swelling of a joint, and often the fact that they took to bed, were all too obvious to escape notice; and then when the change was made to whisky these symptoms disappeared, although all the other conditions surrounding the patient—the diet and general mode of life—remained precisely the same all the while.

3. *Better-class patients.*—At the present time I have under my care a woman, aged thirty-four years, who has for five or

[5] The juice of two lemons, the yellow rind pared thin of one lemon, twelve lumps of sugar, enough citric acid to barely cover the handle of a salt spoon, one and a half pints of boiling water; set aside until cool.

A Table of Approximate Compositions to show the Relative Proportions of Alcohol, Sugary Substances, and Acidity taken in a single Potion of Spirit, Wine, and Ale respectively. The compositions given represent an average of all the available analyses given in several of the current text-books.

	Alcohol.		Sugary substances.		Acidity, either free acid or in loose combination as an acid salt.	
	Average percentage of alcohol by volume.	Usual dose at one time.	Average proportion of sugar.	Usual dose at one time.	Average proportion of acidity.	Average dose at one time.
Spirits	40 per cent.	1 oz. of spirit, containing from 3 to 4 drachms of alcohol.	From 0 to ½ gr. per oz.	1 oz. of spirit containing from 0 to ½ gr. of sugar.	From 0·2 to 1 gr. per oz.*	1 oz. of spirit, containing from ⅕ to 1 gr. acidity.
Heavy wines such as—						
Port	20 per cent.	2½ oz. of wine, containing from 3 to 4 drachms of alcohol.	20 grs per oz.	2½ oz. of port, containing 50 grs. sugar.	2 grs. per oz.†	2½ oz. of port, containing 5 grs. acidity.
or						
Sherry			8 grs. per oz.	2½ oz. of sherry, containing 20 grs. sugar.	3 grs. per oz.†	2½ oz. of sherry, containing 7½ grs. acidity.
Light wines, such as—						
Claret	10 per cent.	4 oz. of claret, containing about 3½ drachms of alcohol.	1 or 2 grains per oz.	4 oz. of claret or hock, containing from 4 to 8 grains of sugar.	2 grains per oz.†	4 oz. of claret, containing 8 grains acidity.
or						
Hock and Champagne...	13 per cent.	4 oz. of hock, containing about 4½ drachms of alcohol.			3 grains per oz.†	4 oz. of hock, containing 12 grains acidity.
Ale	5 per cent.	10 oz. of ale, containing 4 drachms of alcohol.	From 20 to 40 grains per oz.	10 oz. of ale, containing from 200 to 400 grains of sugar.	From 1 to 1·5 grains per oz.‡	10 oz. of ale, containing from 10 to 15 grains acidity.

* Reckoned as tartaric acid.

† Consisting of racemic, tartaric, acetic, malic, tannic (in small quantity), glucic, succinic, carbonic, and fatty acids, such as formic, butyric, or propionic acids, and acid tartrate of potash; fixed acids being reckoned as tartaric acid, volatile acids as glacial acetic acid.

‡ Consisting of lactic, acetic, succinic, malic, and gallic acids; fixed acids being reckoned as tartaric acid, and volatile acids as glacial acetic acid.

six years, been passing large quantities of uric acid crystals, and amorphous lithates from time to time; and who has also presented the listlessness, want of energy, tendency to headache, and all the classical symptoms of lithæmia. In her case the effects are very similar; small doses of pure spirit well diluted and with meals only do not aggravate any of the symptoms, but a single glass of ordinary good champagne is followed the next day, sometimes sooner, by stiffness and pain in the joints, headache, lethargy, &c.; and the taking of any sweet wine, such as port, is followed by a more prolonged disturbance. It is unnecessary to refer in detail to many other cases which could be quoted of gouty and rheumatic conditions and of lithæmia (which are only too familiar to the profession); they all practically tell the same tale. In brief, alcoholic stimulants aggravate the symptoms of these conditions precisely in proportion to the amount of sugar they contain; and the reason that beer and the heavier, i.e., sweeter, wines, as ordinarily met with, are so inimical to these conditions is readily explained by a glance at the table given above, where it will be seen that the amount of sugary substances contained in the ordinary dose of wine may be 20 or more times as large as that in pure spirit, and that in beer they are from 200 to 400 times (!) as great. If both wine and beer were equally harmful it might be contended that the acidity (column 3) was the deleterious constituent, but in my experience, personal and other, beer is much more harmful than wine (tried, of course, under similar conditions), and we are driven to the conclusion that this difference of effect can only be accounted for by the enormous difference in the sugar contained in an ordinary dose of wine and beer respectively.

4. *Public opinion.*—It is not always well to pay much attention to popular beliefs, but so deeply rooted in the minds of many intelligent and scientific persons is the idea that ordinary beer is more potent than wine or spirits to aggravate rheumatic and gouty conditions, or to produce in them—even when apparently healthy, though living a town life—the lethargy, headache, &c., which we know to be due to lithæmia, that one is bound to admit this popular belief as evidence in support of the contention that it is the sugar which does the harm. The enormous increase of late years in the consumption of good whisky and of Pilsener and Lager beers—i.e., beers containing a lower percentage of saccharine constituents—is only an expression of the same firmly rooted belief. Personally, I find that these lighter ales do produce symptoms, though perhaps in a less degree than ordinary English beer.

5. *The immunity of the Scotch.*—Gout is practically unknown among the working-classes in Scotland. Professor McCall Anderson informs me that he can only remember one case which was undoubtedly gouty admitted during the whole of his twenty-five years' experience at the Western Infirmary, Glasgow, and this was in a man who came from Yorkshire, whose chief beverage had been beer. The absence of this disease in Scotland is fully explained, as Professor Anderson points out, by the fact that the masses of the working population in Scotland drink nothing but whisky. Very striking testimony in support of my opening propositions is to be found in these facts.

6. *Effects of beer when deprived of its sugar.*—All the evidence, then, goes to show that ordinary beer is the worst form of stimulant for gouty and rheumatic cases and for people who, though healthy, have a tendency to these diatheses, because of the relatively high proportion of sugar it contains. But ale is a very popular beverage with many, and I have long endeavoured to find a beer resembling ordinary ale in all respects, but containing no sugar, so that this question might be put to a crucial test by trying the effects of such a beverage, but I have always been assured by brewers that this was impossible. In the autumn of last year my attention was called to a beer which purports to be absolutely sugar-free.[6] In view of what had been told me of the impossibility of manufacturing such an article I asked Mr. Chas. E. Cassal, the public analyst of St. George's, Hanover-square, to analyse this ale for me, and his report fully confirms the statement that it gives "no indications of any fermentable sugar." He also reports that the amount of extractives is "very low," that the acidity is "low" (fixed acidity calculated as tartaric acid, 0·164; volatile acidity as acetic acid, 0·092; total, 0·254 grains of acidity per fluid ounce, as compared with from 1 to 1·5 found in ordinary beer), and that it contains 5 per cent. by weight of absolute alcohol (corresponding to 11·08 degrees of proof spirit). The results of my investigations into the action of this beer up to the

[6] An analysis of this beer appears in THE LANCET, May 22nd, 1897.

Digitized by Google

present time afford additional and, as it seems to me, conclusive proof that it is the sugar of alcoholic beverages which does the mischief in gouty and rheumatic conditions. During the last ten months it has been tried in one patient who had consulted me for lithæmia, two cases of chronic muscular rheumatism, one case of chronic gout, one case which I believe to be uric-acid headache, and one case of chronic rheumatic arthritis (in addition to the case of this complaint mentioned below), besides a large number of persons who, though healthy, cannot take ordinary ale. In none of these instances has it been followed by any pain, stiffness, lethargy, headache, or any of the ill-effects which follow the use of ordinary beers or wines. As for myself, for years I have been unable to take beer as a beverage, on account of the lethargy, indigestion, pain, and stiffness which invariably followed such indulgence, but for three months continuously I have taken one glass of this sugar-free pale ale at luncheon without the slightest "rheumatic" effects; and, what is to my mind even more to the point, without interfering with my afternoon's work. This beverage resembles ordinary ale in every respect, excepting that it is deprived of its sugar, and these facts, therefore, show conclusively that it is the sugary constituents of beer which produce the lethargy and other evil effects which follow ordinary beer.

7. *Champagne.*—Let us now turn to champagne, Dr. Harley's remarks concerning which gave occasion for this article. He says (p. 15): "It may, however, be laid down as a general rule that the less acid and the less alcoholic a wine is the less likely is it to disagree with a gouty patient. Hence it is that the sour forms of champagne at present sold in England should in all cases be shunned, no matter what one is told by the uninitiated to the contrary. Champagnes such as the French themselves drink are the safest, for that sugar gives gout is alike contrary to scientific teaching and every-day practical experience." Now this wine as ordinarily met with varies widely in composition, but is always and necessarily a more or less acid—as, indeed, all white wines are—and usually a highly sugary beverage,[7] although the sugar, especially in the newer wines, is generally covered by the "doctoring" which, as Dr. Harley correctly points out,[8] it undergoes for the English market. Not only do the grapes differ widely, but the mode of manufacture varies considerably also, and especially as regards substances added to suit the English palate. Wine that is dry by age—i.e., where nearly all the sugar has become converted by fermentation into alcohol—is one thing, but wine that has been made dry by the addition of acid substances (such as acetic acid) and liqueurs, such as happens to most of the wines specially prepared for the English market, is quite another. In the manufacture of all champagnes a certain amount of sugar is added (usually about 3 kilogrammes of sugar-candy to the 100 litres) to provide for the further fermentation which produces the sparkle, and also a variable quantity of brandy or "liqueur" of a kind which doubtless varies considerably in quality. To get rid of all this sugar by the slow fermentation which goes on in bottle would verily require ages. Taking those wines only of which certified analyses could be procured, the average composition of ordinary champagne, as met with in England, consists of alcohol from 5·8 per cent. to 13 per cent. (by volume), and sugar from 1·36 per cent. to 6·34 per cent. In Parkes' "Hygiene"[9] the average amount of sugar is stated to be 24 grs. per ounce (5·44 per cent.); and the total acidity (present in all *white* wines) varies from 0·74 to 1·63 per cent. There is, however, a variety of champagne which differs in its analysis considerably from the champagne usually met with in the English market. Frezenuis's analysis of this champagne shows alcohol 14·10 per cent. (by volume); sugar, calculated as dextrose, 0·17 per cent.; total acidity, 0·78 This shows that all the natural glucose has undergone total fermentation and that there is no added sugar.

In view of the above facts it is not surprising that champagne as ordinarily met with is a potent agent in producing various gouty and rheumatic troubles—at least, so I have found it, and all those with whom I have conversed on the subject, including many professional and lay persons of great competence. But apart from its value as a remedial agent on account of the nascent carbon dioxide it contains, champagne is a very popular beverage, and when consulted by a patient suffering from gouty or rheumatic pains, or any of those numerous minor troubles to which uric acid gives rise, I frequently ask what champagne they have drunk, and have often been able to trace the causal agency to this. But in the case of the sugar-free champagne to which I have just referred this does not appear to be so. I have myself taken it from time to time for two or three years, and have never found it produce any of those rheumatic or other consequences which always in some degree attend other kinds. This is also the experience of others who could be mentioned, and who, having both the means and the taste for champagne, have tried many different kinds. One gentleman especially who used to consult me from time to time for minor uric acid troubles, but whom I have not seen for many months now, wrote me only a few weeks ago: "As long as I keep to this champagne I am all right, but as soon as I return to the other kinds something goes wrong."

Many more facts might be mentioned, but they are unnecessary in view of this second proof of a kind which Mill called the "double method of agreement and difference," viz., here are two alcoholic beverages possessing *all the usual qualities and composition of such beverages*, with the single exception that they *are wanting in sugar*, and which can be taken with perfect impunity by persons who, whether ailing or in health, cannot take other beers or champagnes without the risk of ulterior consequences, immediate or remote.

8. *Cases requiring stimulants.*—So far we have seen that gouty and rheumatic patients may take alcoholic beverages free from sugar without harm, but the following cases show that, under certain circumstances, these patients actually may *derive benefit from their use.* Take, for instance, a case where the alcohol aids a failing heart or the bitter of the hop improves a weak digestion. A woman, seventy-one years of age, of somewhat plethoric build, has consulted me many times during the past two years for chronic bronchitis and rheumatic arthritis. She has always a certain amount of dropsy of the legs, due to dilatation of the right ventricle consequent on her bronchial trouble; in short, the case represents a type which must be very common in the experience of every practitioner. She has always been very partial to one glass of ale with her mid-day dinner; indeed, she says she has no appetite for her food without it, and that she must have it in spite of the increased stiffness and pain, sometimes accompanied by enlargement of joints and irritability of temper, which ordinarily followed such indulgence. For over six weeks she has taken one glass of sugar-free pale ale with her dinner and supper without the slightest pain or inconvenience, and has enjoyed her meals, because she says it has so much improved her appetite. The dropsy also is slightly less, though she still resists my advice to lay up, and her cardiac condition has greatly improved with the small quantity of alcohol with her chief meal. Space forbids further detail, but one case of diabetes mellitus, aged seventy-two years, which Haig[10] maintains is associated with uric acid, and of obesity, treated on the plan elsewhere described,[11] have been allowed the same article with advantage.

9. *Cases benefited by stimulants.*—Two very severe cases of migraine, apparently of uric acid origin, have also been markedly benefited by alcohol and a liberal dietary. It is now five years since I saw a patient, a woman aged forty-three years, in consultation. She had suffered from time to time for upwards of ten years prior to that date with severe attacks of "sick headache," which were often followed by vomiting and excess of uric acid in the urine. She had seen many medical men and had tried a great many remedies and different modifications of diet, all of which had been directed to the diminution of nitrogen and a general reduction of food, but without avail, and had lost flesh considerably in consequence. In view of the failure of these measures it occurred to me to suggest the opposite plan—viz., four liberal meals of easily assimilable food, two glasses of very old dry Burgundy (which, when really old, is one of the most sugar-free wines) with lunch and two with dinner, and between meals a tumbler of egg-and-milk thrice daily, so arranged that she had nourishment every three or four hours throughout the day. This had the desired effect, and I learn that ever since she adopted this dietary she has been comparatively free from her troubles. About the same time I was consulted by a

[7] In Parkes' "Hygiene" (p. 331) the amount of sugar is said to "vary from 6 to 28 grs., average 24 grs. per oz.," so that a glass of ordinary champagne may contain between 18 and 24 grs. of sugar.

medical man, aged about forty years, who, in a word, was suffering in precisely the same way as the previous patient. His headaches were getting so severe as to impede his practice. I treated him precisely in the same way—a method, be it observed, contrary to all the canons of uric acid, but, nevertheless, attended with a very large measure of success, though not quite so marked as in the previous case.

Before concluding it is only right to add that in all the cases above referred to in which a trial and comparison of the effects of the different kinds of alcoholic beverages have been made attention was paid to the digestive organs and the state of the bowels, which in all such cases is a matter of considerable importance. This is best accomplished by the regular administration of some natural laxative diuretic mineral water each morning I have on a previous occasion[12] pointed out the value of one-fourth or one-third of a tumbler of such water with an equal quantity of hot water taken each morning on waking for keeping the digestive organs in good order. This plan clears away the half-digested products of the day before, so that the ptomaines and other products of imperfect digestion do not remain to become absorbed or to interfere with the digestive processes of to-day. I have not entered into the large question of how or why it is that sugar-containing alcoholic beverages do harm; but clinical evidence seems to indicate some check in the elaborative and oxidative changes which are carried on in the liver and tissues, and this results in an imperfection in the general katabolic processes of the body. Consequently any disorder in the digestion, gastric or intestinal, would greatly aggravate this condition by throwing into the portal vein imperfectly elaborated products of digestion. If this be so it can readily be understood how it is that a natural laxative diuretic mineral water of this kind, by acting on the kidneys and clearing the intestines of these products, comes to be of so much value in gouty and rheumatic conditions, in addition to the various disorders which I have mentioned in the article just referred to; and not being succeeded by constipation as so many other aperients are it can be taken continuously with benefit. A small quantity each morning is better than large doses occasionally.

In the foregoing fragmentary remarks reference has not been made, for want of space, to many additional cases and facts which might have been quoted in support of my opening propositions. But I trust that enough of my own experience and that of others has been adduced to show that pure ethylic alcohol taken at meal times and in a dilute form is harmless, and, moreover, that it may sometimes do good; that it is the sugar in alcoholic beverages which is the most harmful constituent, and that the evil effects vary in proportion to the amount of sugar which is present. The question why the sugar in alcoholic drinks is so harmful is too difficult and too elaborate a question to answer on the present occasion. This problem is not rendered easier by the fact, to which reference has already been made, that teetotal syrups, sweetstuffs, and the like can be taken in much larger quantity and for a longer time without producing rheumatic effects in healthy persons, and even in gouty and rheumatic cases, excepting and unless dyspepsia ensue. In this respect I quite agree with Dr. Harley, who adduces seven illustrations of this circumstance; and I would ask the reader to observe the composition of my own staple beverage until lately. But it is evidently the alcohol and sugar *in combination* which jointly do the harm. Possibly the sugar, by disturbing the digestive processes, however slightly, prevents the alimentary system (including, of course, the liver) from dealing adequately with the alcohol introduced at the same time (as it would otherwise do in an undisturbed state). There are very good grounds for believing that the sugar makes a demand on the same physiological processes as the alcohol; and, both being highly diffusable or absorbable substances, it is possible that the *sudden* demand simultaneously made on the economy by 4 drachms of alcohol and 200 or 300 grains of sugar (the quantities contained in half a pint of ordinary beer) *together* is too great to be satisfactorily dealt with, and so one or the other, or both, pass almost unchanged into the general blood circuit, and give rise to the symptoms some of us know so well. But whatever be the explanation the clinical facts above referred to are beyond dispute.

As regards the part taken by the acidity, I do not wish to contend that it is altogether harmless, but sufficient evidence has been adduced to show that it does not play the leading *rôle*. A glass of some kinds of hock and one of beer may be alike as to acidity, but there can be no question as to which is most harmful. And, on the other hand, sugar-free slightly acid articles can be taken with impunity. If there be much acid (say, roughly, anything over ½ gr. per oz. in spirits, ¼ gr. per 3 oz. in wine, and 1 or 2 grs. per 10 oz. of beer) undoubtedly it may disagree. If in large excess the acidity may perhaps produce some of the same "rheumatic" effects which sweet wines do, and undoubtedly acid wines and other drinks are apt to upset the digestion. This is admitted, but that it does not produce the far-reaching effects which sugar does is evident from the trials above alluded to. A few grains of bicarbonate of soda at the conclusion of the meal will, as aldermen know full well, counteract the effects of the acidity; but not of the sweet alcoholic drink. There seems to be a marked idiosyncrasy in respect to acids, for in some persons a very slight acidity may have a very potent effect. A gentleman I know perspires profusely across the forehead whenever he takes even slightly acid wines, although the acid taste may not be perceptible to the palate; and a very small excess of acid will upset him.

In conclusion, there are not, so far as I am aware, any experiments bearing on this most important practical subject besides those of Buchner,[13] which go to show that a solution of alcohol not exceeding 10 per cent. does not impede artificial digestion, but one of over 10 per cent. does. This is just the limit usually found in ale. But I have no great faith in inferences drawn from artificial conditions which *appear* to imitate gastric digestion, and which are based on what the late Dr. W. H. Stone used to call "the test-tube and pipkin theory of medicine." Against actual clinical experience such experiments—when one remembers the extremely complex and almost unknown conditions present in the human stomach at any given moment—really count for very little.

DEATH FROM SWALLOWING CHLOROFORM.

BY H. E. BRIDGMAN, L.R.C.P. LOND., M.R.C.S. ENG.

JUDGING by the fact that many text-books on poisons do not allude at all, or only in the most casual manner, to poisoning by swallowing chloroform, I conclude that such an occurrence is somewhat rare. The following notes of a case may therefore be of some interest.

A small, spare man, of very nervous, excitable temperament, aged forty-three years, with damaged mitral valves and adherent pericardium due to an attack of acute rheumatism, had been suffering from sleeplessness consequent on mental distress. On the night of June 30th he returned from business rather late, had a good supper, and retired to bed about midnight. I was called to him on July 1st and saw him first at 10.15 A.M. He was dazed and his manner was incoherent, but on being roused he could answer questions intelligently. The room smelt strongly of chloroform, and the patient's breath was saturated with chloroform vapour. The pupils were dilated, but acted slowly to light. The pulse was irregular, about 65 per minute, but of fair volume. He complained of severe pain in the umbilical and hypogastric region. The bowels had acted several times, and there was constant desire to defecate with much straining. He had vomited once, the vomited matter consisting of some bile-stained fluid smelling strongly of chloroform. The lips were quite normal, but the tongue and back of the throat were red, and the patient described them as being very sore. An ordinary two-ounce phial, containing about an ounce of chloroform, had been found under the patient's pillow, and he said that he had swallowed the other ounce at about 7 A.M. to make him sleep. I was informed that a few minutes after 7 A.M. the patient had called a friend who slept in the next room, had complained of not having slept all night, had said he thought he should go to sleep now, had given some directions

Digitized by Google

with regard to his business, and had then fallen asleep before the friend left the room. The friend looked into the room twice afterwards, but noticed nothing unusual until 9.30 A.M., when he sent for me. Between 10 15 A.M. and 12.15 P.M. the patient continued to fall asleep for a few minutes at a time, waking again very shortly on account of the abdominal pain. While sleeping at 11 30 A.M. the pulse was 120, regular, and of fair strength. The respirations were 56 per minute and shallow. At 12 20 P M. the patient commenced passing blood from the bowels. When I saw him at 2 P.M. he had passed about 4 oz. of loose, dark clots and about a pint of highly blood-stained fluid fæces. Vomiting had now become frequent and the vomited matter was slightly blood-stained. As no urine had been passed, notwithstanding frequent attempts accompanied by painful strainings, a gum elastic catheter was passed and about half an ounce of blood-stained urine was drawn off. By this time the smell of chloroform in the breath was slight, there seemed little tendency to sleep, and the patient's mind was perfectly clear and remained so up to the last. At 4 P M. the pulse was 120, weaker, and more thready; the respirations were 30 per minute, the hæmorrhage from the bowels had subsided, and the vomiting was less frequent. The abdominal pain was very intense. Though gradually getting weaker the patient's condition remained much the same until about 7.30 P.M., when he suddenly grew worse and died.

Remarks.—This case is interesting, as death appears to have been entirely due to the effect of the chloroform as a violent irritant poison. The immediate narcotic effects of an ounce of chloroform seem to have been comparatively slight and to have been entirely recovered from. In the absence of a necropsy it seems difficult to say with certainty what was the immediate cause of death; but looking at the symptoms it is not unreasonable to suppose that there may have been perforation somewhere along the intestinal track. In a case reported in the *Medical Times and Gazette*, of Nov. 28th, 1857, the stomach was found, post mortem, to be inflamed in patches and the mucous membrane to be softened. The treatment was directed to sustaining the heart's action, to relieving the pain, and checking the hæmorrhage and sickness. Liquor strychniæ and spiritus ammoniæ co. were administered and a hypodermic injection of digitalis was given. Small doses of opium were given from time to time and hot fomentations applied to the abdomen. Ice was given by the mouth and iced injections were administered, which had a marked effect in stopping the hæmorrhage and relieving the tenesmus.

Burton-on-Trent.

ON SOME GERMAN SANATORIA FOR PHTHISIS.

BY F. RUFENACHT WALTERS, M.D., M.R.C P. LOND.,
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION.

HAVING recently visited three of the German institutions for the treatment of phthisis—those at Falkenstein and Ruppertshain in the Taunus district, and the one at Hohenhonnef on the Rhine—it may interest some of my professional brethren to read a brief description of these places and their methods of treatment. All three institutions owe their existence in great measure to the influence of Dr. Dettweiler, and are therefore conducted on much the same lines. But while the Ruppertshain building is intended for those of small means, and somewhat resembles an English convalescent home for phthisical hospital patients, the other two are almost or quite unrepresented in England, being devoted to patients who are able to pay remunerative fees. Whenever the climatic treatment of phthisis is mentioned in this country most medical men would at once think of an Alpine or marine station, or an elevated table-land such as those of South Africa and Australia. But it should be borne in mind that such climates are by no means essential in every case of phthisis, and that a surprising degree of success may often be obtained in well-conducted and well-designed inland sanatoria, but moderately elevated above the sea-level, provided their sites have been carefully chosen in certain essential particulars. None of the three institutions with which I am just now concerned is in an Alpine climate. Falkenstein is 1300 ft. above the sea-level, and possesses a climate somewhat resembling that of some of our own hills. It is by no means free from fog, has a rainfall varying from half an inch to seven and a half inches per month, and a temperature which is rather lower in winter and a little higher in summer than that of the south of England. With all these drawbacks it is able to report about 25 per cent. of its patients as practically cured. Hohenhonnef is 770 ft. above the sea-level, and has much the same climate, but is probably less rainy and less protected. Taking into account the difference in geographical position, such elevations probably correspond climatically with lower elevations in our own land, and cannot be said to owe their value to an Alpine character.

From the diversity in temperature, moisture, rainfall, and elevation of the various health resorts for phthisical patients which all show a more or less satisfactory record, it is clear that either these factors are not of prime importance or else that different cases require different conditions. There is probably some truth in each of these conclusions. The essential conditions appear to me to be the following. In the first place the soil must be dry and warm, and thoroughly drained; in the next place the air must be pure and free from dust and smoke. There should be enough atmospheric circulation to keep the place dry and well ventilated, but ample protection against strong or cold winds. It is a common experience that most cases of early phthisis do best in a moderately bracing climate; but just as cold baths may be stimulating to one person and depressing to another, so in climate a place may be bracing to this patient, but altogether too keen or too windy for another. No place with a stagnant atmosphere is likely to be suitable in phthisis, and excepting in certain stages and for certain complications a moderate variation in temperature is likely to do good. Strong wind, especially if also cold, does much more harm in pulmonary tuberculosis than in other forms of tuberculous disease, and efficient wind-screens—natural or artificial—are essential in a health resort of this kind. Dust is also very bad for phthisical patients, and some very damp and rainy places are yet good for phthisis, probably in great part because of the absence of dust. Plenty of sunshine is a valuable aid to recovery, not so much from its bactericidal properties as from its influence on general nutrition. But the experience of Falkenstein, which shows very little difference between summer and winter in the proportion of patients who have to keep their beds, proves that sunshine is not as essential as many of us have been inclined to believe. Given plenty of warm clothing and protection against cold winds, phthisical patients in the quiescent stages can remain with advantage in the open air from morning till night even in wet and sunless weather. This is a great feature in the treatment at all these German institutions, where even foggy weather or severe frost and snow are not held to be indications for keeping the patients indoors. My visit to Falkenstein was paid during somewhat chilly and wet April weather, but nearly all the patients were lying out as usual on their cane sofas. The amount of exercise which is good or safe for phthisical patients depends largely on their strength. Febrile and much debilitated patients must be kept at rest; those who are free from fever and moderately strong may take a good deal of exercise, provided they do not go quickly so as to get out of breath. In most of these German sanatoria the paths are arranged in gentle inclines, so that patients may go gradually uphill and return downhill, increasing the distance and difficulty of their walks in proportion to their growing strength, under the directions of the physician, just as is done in heart disease. Such graduated exercise is a great feature at the Goerbersdorff Sanatorium; but at the three with which I am now concerned more stress is laid on rest in the fresh air. In each establishment there are numerous verandahs and summer-houses, where patients lie in the open air on cane sofas, well covered up and well protected against wind and rain, only coming in for meals. To diminish the liability to chills great attention is paid to the hygiene of the skin, which is trained to accommodate itself to atmospheric variations by systematic rubbings with spirit, or the cold, wet sheet, or by douches under the direction of the physicians. At Hohenhonnef cold ablutions are considered sufficient in most cases, and the douche is less used than in the older establishment. It is also found, as would be expected, that an open-air life renders patients less liable to chills. It is one of the problems of such institutions how to ensure rest and quiet without dulness. Beautiful scenery is a great help in this respect; but much will also

Digitized by Google

depend on the physicians and their colleagues. The mental factor should indeed never be lost sight of, as it may make a great difference in the results of treatment. Much ingenuity may also be profitably spent in designing the building for such an establishment. It should, of course, be as nearly as possible faultless from a sanitary point of view; but it is unnecessary to dwell here on its construction, as a description of the institutions I have just visited will be of more interest.

Falkenstein Sanatorium is about ten miles north-west of Frankfort-on-the-Main on the southern slopes of the Taunus Mountains, at the upper end of a valley which is exceedingly well protected on the west, north, and east by hills of from 1500 ft. to nearly 3000 ft. above the sea level. The surrounding country is extremely picturesque and well-wooded with extensive forests of beech and other trees. The sanatorium, which has a south-easterly aspect, is built in the shape of a centre and two wings, which diverge from it at an obtuse angle and enclose a stone terrace with deep verandahs, under which the patients lie on cane sofas. From this terrace there is a magnificent view over Cronberg and the low-lying country extending to Frankfort, across which the Main is clearly visible. The central block consists on the ground floor of a large winter garden and a reading-room and cloak rooms, and has in front a well-lighted corridor looking on to the verandah and extending to the wings. Behind are the entrance, grand staircase, porter's lodge, and post and telegraph offices. The ends of the wings contain, one a music-room and a conversation-room, the other a billiard-room and library. The handsome dining-hall, which is placed in a separate building over the kitchens, communicates through a vestibule with the eastern end of the central corridor. It is 78 ft. long, 39 ft. wide, and 32 ft. high, and can easily seat 200 guests. In front of this, diverging at an obtuser angle than the eastern wing, is a corridor 200 ft. long, which leads to the eastern annex. This is a separate building now entirely occupied by patients' rooms. A similar but shorter corridor on the other side of the central block leads to the western annex, of which the basement contains the bath and douche rooms, the rest consisting of laboratories, consulting-rooms, and the private rooms for the three medical men and their establishment. The upper part of the centre block and wings, which is partially built of wood, is occupied by bedrooms in two storeys, with smaller ones in the attics. Some of these bedrooms have balconies, one in the centre over the winter garden being a very large one. On the other side of the road which runs behind the sanatorium, are stables, model cowsheds, and pig-sties, the laundry, steam disinfecting apparatus, and the machinery required in the production of oil-gas for lighting purposes. The latter, when I visited it, was remarkably free from smell. The directors are hoping in the future to instal electric lighting, but there are at present difficulties in the way. The water-supply, which is abundant and of excellent quality, is derived from private springs at the top of one of the neighbouring mountains; but in case of drought there is a supplementary supply from Cronberg. The drainage system, which was constructed in 1883 under the direction of an English engineer, appears to be very good and complete. The water-closets, although not built out, are of good pattern. The sewage, with the rest of the waste water, runs into precipitating tanks in a shed in the grounds, where it is treated with acidulated sulphate of aluminium, and repeatedly clarified by a partially automatic apparatus. The solid sludge is mixed with peat, leaves, or earth, and then used in the garden, while the liquid effluent is allowed to irrigate a field. The whole system when I inspected it was free from objectionable smell and seemed to work very well. The sanatorium with its annexes is heated partly by low pressure steam (Bacon's system) and partly by ordinary German stoves. The patients, however, do not spend much of the day indoors. Excepting at meal times and when consulting the medical officers they lie under cover out-of-doors in the numerous summer-houses or "Liegehallen" with which the grounds are provided, or under the verandah which looks on to the terrace, or take walks, regulated by the medical officer, in the grounds or adjoining woods. These "Liegehallen" are of various shapes and sizes, built substantially of wood and provided with cane lounges or sofas, like those on the terrace, as well as with little tables and other simple furniture. Each patient has his own place, which he can decorate with flowers, pictures, fans, &c., according to taste. Even some febrile patients lie out in these places from morning to night, regardless of rain, cold, or fog, and apparently with great benefit. Patients with acute exacerbations or complications are, however, kept in their bedrooms. There is a strict rule enforcing the use for all expectorations of Dettweiler's flasks or of ordinary spittoons, many of which are placed in the grounds. The dietary seems to be exceedingly good and suitable. The milk-supply is excellent, the cows being regularly tested with tuberculin and all doubtful ones replaced. I was told by a patient that complaints are very common about the food, but these do not seem to me to be justified, if one may judge from a few days' stay. I was informed that the *menu* is chosen to suit the various nationalities in turn, but it must be a task of some difficulty to successfully cater for so cosmopolitan a community. German ways are very different —in food as in other things—from French or English; there are even decided differences in the dietary of different parts of Germany, and what would please one patient might be most distasteful to others. The sanatorium is capable of accommodating over 150 patients, besides those who sleep in the village. The three resident physicians—Dr. Hess, Dr. Besold, and Dr. Adolf Koch—are exceedingly popular with their patients. I cannot speak too highly of their courtesy in giving me the fullest opportunities of investigation, while their thoroughness and devotion to their duties were equally remarkable. They use drugs very sparingly, but pay great attention to the throat complications of phthisis. They have begun to use Koch's new tuberculin for about a dozen patients, but have little or no belief in other reputed specifics. The douche is much less used than formerly, but spirit-rubbing and friction with a wet sheet are systematically done, whenever there are no contra-indications, in order to train the skin to withstand changes of temperature, to check the habit of profuse perspiration, and to improve the general nutrition.[1]

The sanatorium at Ruppertshain is situated in a neighbouring valley about forty minutes' drive from Falkenstein. It has a somewhat similar outlook and sheltering hills, but a more easterly aspect. The building forms part of a circle, the rooms being connected with corridors at the back. Several patients are accommodated in each room, and the furniture and fittings are somewhat plainer than at Falkenstein. There is a large dining-room for the women on one floor, and one for the men on the floor above. The kitchen is situated in a separate block at the south-west end. The terrace is at present somewhat exposed, but when the newly-planted trees have grown it will be better protected. The place, which accommodates eighty-five patients, is heated by low-pressure steam. It was partly built by money earned at Falkenstein, which gives it an annual subvention. Although intended for necessitous patients, these have to pay rather more than one would expect in a similar institution in England; but I understand that the weekly payments are often defrayed by friendly societies. It is simply constructed, carefully designed, and well fitted for its object. I have to thank the resident medical officers for showing me over the building and giving me full explanations of the many interesting features possessed by the sanatorium, which is of quite recent construction.

The sanatorium at Hohenhonnef, although smaller than that at Falkenstein, is a more modern building, and is marvellously complete in its details. It is situated on a hill on the right bank of the Rhine in one of the most beautiful parts of this lovely district, the view extending over the river to the Eiffel Mountains, while the famous Drachenfels forms one of the neighbouring peaks. The sanatorium is built of white stone and plaster in a somewhat conspicuous position, which gives the impression that it is unduly exposed; but the surrounding hills on the north and east are from 300 ft. to 700 ft. higher than the sanatorium, so that, excepting on the south-west, it is fairly sheltered from violent winds. The slopes of the hills towards the river are clad with vineyards or woodland, while a beautiful forest of pine trees protects the building on the landward side. Many more trees have been planted on the hillside near the sanatorium, so that in a few years' time there will be plenty of shelter on all sides. The building consists, as at Falkenstein, of a centre and two diverging wings, the latter a trifle more opened out than at the older sanatorium. The front has a south-westerly aspect, the entrance being at the back. The basement, which is on a level with the terrace in front, is occupied by cloak-rooms, bath- and

[1] Dr. Bezly Thorne has also described this institution in a lecture before the Royal British Nurses' Association.

Digitized by Google

douche-rooms, furnaces for heating the building, and a limited number of bedrooms for visitors who are not patients. On the ground floor are handsome reception rooms, reading-room, music-room, ladies' room, billiard-room, winter garden, consulting-rooms, laboratories, a suite of rooms for the managing director, and a few bedrooms for patients, while behind are the post-office and bureaux. Above this floor are three storeys occupied by bedrooms, all in the central part being situated in front, and many having balconies. Four large balconies are placed at the back for use in hot weather. Part of the western wing is at present occupied by the medical officers' private rooms, but these will shortly be available for patients, as new houses are being built in the grounds for Dr. Meissen and the managing director. There are lifts for patients in the sanatorium and rooms for convalescents and nurses' bedrooms on each floor. The handsome dining-hall is situated above the kitchen and store-rooms in a separate block behind the centre of the building, and is approached by a bridge over the entrance. There is no direct communication between the kitchen and dining-hall. The servants sleep in a separate building to the back of the eastern wing. The whole sanatorium is lighted by electricity and heated by means of hot-water pipes, and is arranged in a thoroughly luxurious style. Even the "Liegehallen" round the building and in the woods are provided with electric lights and bells. The steam laundry, steam disinfector, electric motors, and wells for water-supply are placed about half a mile off in a neighbouring valley, and being of modern construction and shielded by the woods cause no objectionable smells or sounds. The drainage system in-doors is based on English models. The sewage and waste waters are clarified by simple subsidence in tanks, the sludge being afterwards mixed with peat and used as manure, while the effluent is discharged into the Rhine. The tanks were quite unobjectionable when I visited them. It is impossible in a brief description to do justice to the completeness with which every detail has been provided for in this sanatorium, which appears to be a model in almost every respect. The senior medical officer, Dr. E. Meissen, who was for many years assistant to Dr. Dettweiler at Falkenstein, is not only a very charming, but also a most capable man, and my best thanks are due to him and Mrs. Meissen, as well as to his junior colleague, Dr. Schröter, and the managing director, for their great courtesy and attention during my brief stay. The system of treatment is much the same as at Falkenstein. Sputa are disinfected with lysol and soft soap, but no spittoons are seen about the grounds. The food is excellent and well chosen, the milk-supply coming from a model dairy belonging to one of the directors. I was much struck with the friendly, sociable feeling amongst the patients, who seem to be very comfortable and well cared for. There is at present room for ninety-three patients, but there will soon be accommodation for a larger number in the building.

Welbeck-street, W.

A CASE OF SEPTICÆMIA SUCCESSFULLY TREATED WITH ANTI-STREPTOCOCCIC SERUM.

BY ERNEST R. G. GROTH, M.D. BERLIN, L.R.C.P. LOND.,
PHYSICIAN TO THE WESTERN DISPENSARY OF THE GERMAN HOSPITAL.

ON May 13th, 1897, I was called upon to attend a married woman, aged twenty-nine years, who had miscarried in the third month of pregnancy. She informed me that there had been considerable hæmorrhage on the previous day. On examination I found some placental débris in the cervical canal; this I removed and hæmorrhage ceased. The pulse remained at 90 and the temperature for four days did not exceed 99·4° F. There was but slight inoffensive lochial discharge, and boracic acid douches were used twice daily. On the 18th, the fifth day after the miscarriage, the pulse rose to 108 and the temperature to 100·8°. On the 21st the pulse further rose to 120 and the temperature to 103°. The uterus was not much enlarged and was freely movable, but as the abdomen was somewhat distended and slightly sensitive I decided to explore the uterine cavity next day. On the following morning (the 22nd) the pulse was 124 and the temperature 103·8°. In the afternoon Mr. Beer saw the case with me and dilated the uterus with Hegar's dilators under ether. Some hardened pieces of placenta were found closely adherent to the fundus uteri, and as much as could be was removed with the curette with antiseptic precautions, and the boracic acid douche continued as before. The removed débris was quite inoffensive. On the third day after the operation the morning temperature was 99° and the pulse 100, the douche returned clear, and no pelvic inflammation or swelling could be detected. The temperature, however, again rose, and on the morning of the 27th had reached 105 8° and the pulse 136, and symptoms of septicæmia were distinctly developed. A specimen of blood, withdrawn with due precautions, from the finger was examined by Mr. W. D. Severn, of the West-end Pathological Laboratory, who telegraphed that the blood submitted to him "contained a few streptococci." Five grains of antifebrin were ordered, and the temperature fell for a short time to 104·4°. I then decided to treat the case with anti-streptococcic serum, which I obtained from the British Institute of Preventive Medicine. The first injection of 20 c.cm. took place at 3 P.M., and the temperature fell in twenty-four hours from 105·5° to 101·8°. A specimen of the urine was also examined by Mr. Severn, who reported as follows:—

"*Physical examination.*—Urine was cloudy and contained a good deal of fine flocculent deposit; the colour was somewhat deeper than that of normal urine. The specific gravity was 1014·1; the reaction alkaline. The odour was disagreeable and savoured of putrefaction.

"*Chemical examination.*—Serum albumin, distinct trace; globulin, distinct trace; proteose, deutero-albumose was present and some other albumose, which has not been identified; sugar, absent; phosphate (P_2O_5) in excess of the normal amount. A trace of diacetic acid was present, and this was carefully differentiated from acetone. The amount of serum albumin was too small to estimate with anything approaching accuracy without employing tedious and difficult methods. Sugar was tested for by the glucosazon reaction.

"*Microscopical examination.*—Numerous highly granular leucocytes of variable size were present and a few red blood corpuscles, four to six in a field, Zeiss D. oc. 4. The principal feature of the microscopical examination was the presence of some rather coarsely granular casts, which were, however, of small dimensions. A few rather large hyaline casts were also present. Some crystals of calcium triple phosphate and a small deposit of amorphous urates was observed. Cover-slip preparations prepared from centrifugated portions of the urine containing deposit and stained by the Gram-Weigert method revealed large groups of staphylococci, the identity of which it would, of course, be impossible to establish without culture experiments. Two species of cocci were present, the smallest of which were morphologically identical with pyogenic staphylococci. No streptococci were observed, and the above organisms were the only ones present which retained the violet after treatment with iodine, alcohol, and aniline."

Serum injections were made on May 27th (20 c.cm.), May 28th (10 c.cm.), May 29th (10 c.cm.), May 30th (20 c.cm.), June 1st (10 c.cm.), June 6th (10 c.cm.), June 11th, 12th, 13th, and 14th (10 c.cm. each day), and the result of these injections was as follows:—

Date.	Serum injected.	Degrees F.—Morning.	Degrees F.—Evening.
May 27th	20 c.c.	105·8	105·0
,, 28th	10 c.c.	101·8	103 6
,, 29th	10 c.c.	100·8	101·6
,, 30th	20 c.c.	101·2	103 8
,, 31st	None.	101·8	104·0
June 1st	10 c.c.	99 4	100 8
,, 2nd	None.	100·0	104·4

From this date the temperature varied between normal and 102° until June 9th, when it was 103° in the evening. On June 10th it was 105° in the evening, and the injections were re-commenced, with the result of a gradual fall in temperature and pulse-rate. After the fifth injection of serum I discontinued its use for four days, as the pulse and temperature were not very high, but on June 6th I gave another injection of 10 c.cm. The urine was again examined and the abnormal chemical and microscopical features were diminished. On the 8th the patient complained of a rash, accompanied with great itching, succeeded on the following day by pain and stiffness in all joints. The tongue was furred and dry, the throat

Digitized by Google

reddened and painful, the patient was unable to swallow any food, and appetite had disappeared; the abdomen was distended, tympanitic, and painful; and all the septic symptoms, which had previously disappeared, had now returned. As no vaginal examination had taken place after May 24th I examined her again on June 10th, and in the left broad ligament I found a considerable inflammatory swelling. From June 6th to June 11th no serum was injected, but the patient took daily twelve grains of quinine and ten grains of antifebrin in divided doses. In spite of these febrifuges the temperature rose to 105° and the pulse to 120 on the evening of June 10th; I therefore discontinued medicines and again had recourse to serum injections, with the satisfactory result that after injections on June 11th and 12th the rash, itching, stiffness, pain in the joints and throat disappeared, the appetite returned, the abdomen became softer and less tympanitic, the pulse and temperature gradually fell, until on the fourteenth day after the last injection the pulse and temperature became normal and the patient recovered. It is a noteworthy fact that after the last two serum injections the swelling in the left broad ligament decreased in size, and on June 25th there remained but little of it. During the time the swelling decreased the evening temperature was slightly above and the morning temperature slightly below normal; the pulse varied but slightly. After June 26th there was no deviation from the normal pulse and temperature. A third examination of the urine was made after the final serum injection, and abnormal substances had by this time completely disappeared, which goes far to prove that renal mischief is not caused, as some assert, by the serum, but is entirely due to the disease. The total quantity of serum used in this case amounted to 120 c.cm., or 4½ oz. I regret not having made more frequent vaginal examinations, for this would have given the exact date when extravasation in the left broad ligament began and would have made the case more complete. There can be little doubt that the serum alone saved this patient's life. During the course of the case quinine, antifebrin, and a hydrochloric acid mixture were given, but no drugs appeared to have any lasting influence in reducing either temperature or pulse.

A CASE OF GASTRIC ULCER PERFORATING INTO THE PERICARDIUM.

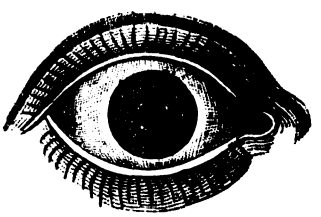
BY COLLINGWOOD FENWICK, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.

ON July 30th, at 5.55 P.M., I was hastily summoned to attend a man who had been taken suddenly ill. Arriving at his house three minutes after receiving the summons I found him lying dead on a garden chair. The history I obtained from the widow was as follows. Her husband's age was fifty-five years, and until recent years he had been a builder. On the day of his decease he returned home from a walk at about 5.30 P.M., but made no complaint and appeared to be in his usual health. He had never complained of pain after food or suffered from vomiting or any other symptom of gastric disease. Immediately on finishing his meal, which consisted of tea, fish, and bread and butter, he rose from the table complaining of pain and palpitation. After walking a few yards he sat down, and his wife, noticing that he looked very pale, administered some whisky and water, but he expired in about a minute.

Necropsy.—The results of the post-mortem examination, made twelve hours after death, were as follows. The body was that of a stout elderly man. The lungs were emphysematous, the right lung being bound to the chest-wall by strong pleuritic adhesions. The pericardium was found to contain several ounces of tea, which smelt of whisky, and some particles of fish. On the lower surface of the pericardium a small aperture was discovered admitting a stout probe, which was passed downwards through the diaphragm into the abdominal cavity. The heart itself weighed thirteen ounces and was extensively infiltrated with fat; the valves were normal. The anterior surface of the stomach was found to be firmly adherent to the under surface of the diaphragm, and on opening the viscus a chronic ulcer the size of a shilling, with indurated edges, was seen to be situated about the centre of the lesser curvature. From the base of the ulcer a sinuous track led upwards and to the right through the substance of the pericardium. The stomach contained fourteen ounces of undigested material, composed of tea, fish, and sodden bread. All the other organs were apparently healthy.

The rarity of perforation of the pericardium by ulceration of the stomach, and the fact that the fatal accident occurred without any antecedent symptoms of gastric disease, appear to me sufficient warrant to place the case on record.

Ferndale-road, Clapham, S.W.



Perforation of a simple gastric ulcer into the pericardial cavity is an event of extreme rarity, and Mr. Fenwick's case is therefore of great interest. We hope to refer to it again shortly.—ED. L.

NOTE ON ARTIFICIAL PUPIL.

BY CHARLES BELL TAYLOR, M.D., F.R.C.S. EDIN.,
SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

WHEN examining patients in whom an artificial pupil has been formed one too often finds that the iris has been excised right up to the corneal margin, as depicted in Fig. 1. This

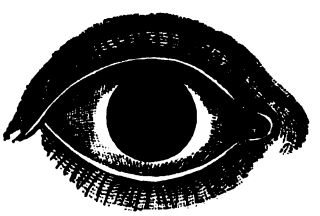


FIG. 1.

Artificial pupil after operation by usual method.

is to be deprecated; the object should be simply to make a slit as small as will answer the purpose opposite a transparent radius of the cornea, the situation of the slit should be inwards in an oblique meridian for choice, and the cornea should be most carefully examined prior to making the selection, as it often happens that the portion seemingly transparent before the operation reveals, opposite the new black pupil, striæ the existence of which was not at first suspected. The late Mr. Critchett sought to secure a sufficiently small pupil by withdrawing a minute piece of iris and fixing the incarcerated prolapse by a suture, M. Wecker by snipping off a portion of the sphincter of that membrane *in situ* in front of the lens, and others by simply

FIG. 2.

Artificial pupil after operation by author's method.

performing an iridectomy more or less up to the corneal margin. Mr. Critchett's operation realised the slit admirably but it was apt to cause glaucoma, prolonged irritation, and even, I have heard, sympathetic ophthalmia. M. Wecker's operation clearly involves considerable risk to the integrity of the lens, and the simple iridectomy is objectionable for cosmetic reasons and on account of the diffused images to which it gives rise.

I have endeavoured to minimise these drawbacks by

Digitized by Google

contracting the pupil with eserine prior to incising the cornea, withdrawing a small piece of the inner edge of the sphincter of the iris with forceps, and, the moment it emerges, excising a minute portion—not larger than a pin's head—with specially sharp scissors. In this way I have for some years past succeeded in securing a stenopuic slit quite as effectually as by Mr. Critchett's operation and with none of the drawbacks attending a strangulated prolapse. The appearance presented by the new pupil after recovery depicted in Fig. 2 is sketched from a patient on whom I have recently operated on account of central opacity of the cornea.

Nottingham.

NOTES ON TWO CASES OF AUTO-INTOXICATION AND PREGNANCY.

By ROBERT CRAIK, M.D. GLASG.

CASE 1.—A healthy young woman, twenty-six years of age, in the seventh month of her second pregnancy, complained of an itchy rash on her body and limbs, but chiefly on her legs. It gave her much trouble at night, the itchiness interfering with sleep. On examination the rash was found to be of the nature of urticaria. A history of gastro-intestinal irritation was inquired for, but there seemed no reason to suppose that indigestion or the ingestion of irritants had anything to do with the causation of the complaint; on the contrary, the patient informed me that soon after the middle of her first pregnancy she began to be troubled in the same way for the first time. On that occasion she was treated with drugs and strict diet for a month without benefit and was much troubled with the rash right up to her confinement, but obtained relief soon after delivery. When I saw the patient her urine was free from albumin, there was no history of rheumatism, and she was not constipated. Several mixtures, including one of salicylate and bicarbonate of soda, were tried, but no relief was obtained, and she was advised to await her confinement. The rash disappeared entirely on the third or fourth day after delivery. The child was healthy and well-developed. She informed me that the rash disappeared much sooner after her first confinement—almost at once, in fact.

CASE 2.—A multipara, aged forty-four years, in the sixth month of pregnancy, was taken with labour pains, and in a few hours gave birth to a fœtus which had evidently been dead for a day or two. It was necessary to remove the placenta by the introduction of the hand into the uterus. All went well and she recovered so far as to be able to sit up in a chair for a few hours a day, but she seemed weak and it was found that she had been very poorly for some weeks before the confinement, although able to be about the house till the day of delivery. She gradually became weaker, and soon had to take to bed again, complaining of pains in the limbs and cramps in the legs. Nothing particular was observed till about a month after the confinement, when it was discovered that the muscles of the calves of the leg were flabby and tender on pressure. Sitting on the bed, with her legs dangling over the edge, it was seen that there was considerable wasting of the muscles and ankle-drop, and the knee-jerks could not be elicited in the slightest degree. Her arms were similarly affected, and the grasp was feeble. She was unable to button her night-dress, she complained of numbness of the hands, and had wrist-drop, though not to the extent often seen in alcoholic paralysis. There was no tremor. These symptoms lasted for about three months, but she ultimately made a very good recovery.

Remarks.—In Case 2 delivery was easy, without much exertion or unusual loss of blood. The lying-in period was non-febrile and otherwise satisfactory. There was no suspicion of intemperance and no evidence of lead-poisoning or syphilis. She had had influenza about a year before, somewhat severely. There was no rheumatic or gouty history. No albuminuria was detected during the illness, but the urine was not tested till a fortnight after delivery. The paresis, muscular atrophy and hyperæsthesia, the cramps, and loss of knee-jerks were symptoms that no one could miss when the illness was fully developed. The sensory disturbance was much less marked than the motor.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF GUMMA OF THE ISTHMUS OF THE THYROID GLAND; ULCERATION; ŒDEMA OF THE LARYNX; LARYNGO-TRACHEOTOMY; RECOVERY.

(Under the care of Mr. BRUCE CLARKE.)

THOUGH gummata of the thyroid gland have no doubt from time to time been noticed, yet very few indeed have been placed on record. Wölfler[1] only mentions one instance of a gumma in the thyroid resulting from acquired syphilis; it was recorded by Navratil.[2] Demme[3] met with three instances in which gummatous masses were found in the thyroid gland in children who were the subjects of hereditary syphilis. We are not aware that any further cases have been recorded. For the notes of this interesting cas we are indebted to the house surgeon, Mr. Maurice G. Pearson.

A married woman, aged thirty-eight years, was admitted into St. Bartholomew's Hospital under the care of Mr. Bruce Clarke on Dec. 28th, 1896. About four years ago she attended as an out-patient under the care of Mr. Bruce Clarke, and suffered from a gumma of the right arm, which subsided under treatment with iodide of potassium. She ceased taking the medicine, and very soon three gummata appeared on the left side of the face, and were similarly cured. About March, 1896, a gumma appeared on the front of the neck, and again iodide of potassium was given; but in September, 1896, the swelling began to ulcerate, and she treated it by poulticing. She had been married thirteen years and had never been pregnant. No history of syphilis or any of its manifestations (apart from the gummata for which she had been treated) could be obtained either from herself or her husband. A fortnight before admission she began to have a difficulty in swallowing and could take no solids. Her voice became a husky whisper, and during the last week her breathing had been difficult. On admission her temperature was 100·3° F., her pulse was 36 and small, and the respiration was 24 per minute. Her breathing was always difficult, and occasionally severe paroxysms of dyspnœa caused the patient great distress. In the mid-line of the neck anteriorly there was a hard, cylindrical swelling, extending from the hyoid bone to the top of the sternum, so that the thyroid and cricoid cartilages could not be felt. The swelling rose and fell with deglutition. Its upper part was ulcerated, and the ulcer was "punched out" in appearance, and on the surface there was a washleather-coloured slough; in fact, it was typically a gummatous ulcer. With the laryngoscope the mucous membrane of the larynx appeared to be very red, but not markedly œdematous. The abdominal and thoracic viscera were apparently normal. Iodide of potassium was administered, but the patient grew worse rapidly; the dyspnœa increased, the left side of the larynx became very œdematous, and a sub-conjunctival hæmorrhage appeared in the right eye. On Jan. 1st she had another attack of severe dyspnœa worse than any she had had before; she sat up in bed and breathed with difficulty and distress, and was evidently greatly frightened; she said she felt she was dying; the pulse was 130 and very small; the respiration was very rapid and constantly interrupted by fits of coughing; the skin was markedly cyanosed. Laryngo-tracheotomy was performed at once without an anæsthetic, as her condition was not considered good enough to stand one; except during the skin incision she did not seem to suffer much pain. It was found necessary to cut through a thickness of

Digitized by Google

one and a half inches of hard, gummatous material before any part of the larynx or trachea was reached. Most of the gumma was divided in the middle line; it appeared to occupy the whole of the isthmus of the thyroid gland and to extend upwards and downwards from it. The cricoid cartilage and the upper two or three rings of the trachea were divided, and a Durham's lobster-tail tube was inserted, as the ordinary tubes had not a shank long enough to reach the trachea. Her condition was relieved at once, the breathing became perfectly easy and slow, her colour improved, and she passed a comfortable night, sleeping well. The iodide of potassium was continued, at first in fifteen-grain doses, but soon increased to thirty grains three times a day. The gumma rapidly dwindled, and large pieces sloughed *en masse*. A piece of the tumour was examined microscopically; it exhibited the character of a gumma, but no thyroid tissue was recognisable, perhaps owing to the sloughy nature of the tissues. On Jan 3rd a laryngoscopic examination was made; the epiglottis, the right side of the larynx, and the right vocal cord were red, but otherwise natural; the left side of the larynx was so œdematous that it projected as far as the middle line, and the left cord could not be seen. No ulceration was visible. The œdema of the larynx subsided, and on the 7th the tracheotomy tube was permanently removed. When the patient left the hospital, on Feb. 6th, 1897, the wound was closed; breathing was perfectly natural and easy; there was still some œdema of the left side of the larynx, and the left cord was almost destroyed, being represented only by a small irregular nodule of tissue. Her voice was still the same husky whisper that it was before operation. It was at first doubtful whether the whole thyroid had sloughed away or not, but the patient has been seen lately (June, 1897), and no signs of myxœdema have appeared. The voice is just as before, and the only change in the larynx is that the œdema has entirely gone. Her general health is excellent.

Remarks by Mr. BRUCE CLARKE.—The rarity of gumma of the thyroid gland, and, indeed, of any gland tissue, is such that the above case deserves to be placed on record. In the earlier stage before ulceration began the gland was well mapped out, and pretty uniformly enlarged, but later the surrounding tissues were so infiltrated that its earlier characters were entirely masked.

HALIFAX ROYAL INFIRMARY.

A CASE OF POLYPUS OF THE EPIGLOTTIS; SUB-HYOID PHARYNGOTOMY; NECROPSY.

(Under the care of Dr. PRIESTLEY LEECH.)

A MAN, aged fifty-four years, was first seen in the early part of January, 1897, by Mr. Topham and Dr. Marshall. The patient then complained that he was always "swallowing wind." On examining his throat a cystic-looking tumour about the size of a Tangerine orange was seen lying in the pharynx just behind the base of the tongue. On Jan. 11th he was seen by Dr. S. Lodge, jun., to whom the patient had been referred by Mr. Topham. The following notes of his condition at this time are by Dr. Lodge. Two years ago the patient first felt the sensation of having a lump in his throat; this lump seemed to change its position. Eructation of wind eased this sensation probably by a lifting of the tumour from the gullet. At first there was only dysphagia, but latterly odynephagia had been fairly constant, at first only for liquids, but afterwards for solids as well; fluids often regurgitated through the nose. Dysphonia came on still later; odynephonia was only present when the throat was dry. There was complaint of pain about the ears and the base of the neck; the pain was aggravated by bending the head backwards. He always slept with his head hanging forwards in bed. The nose and naso-pharynx were free from disease. The patient, a tall, spare man, had during the past three months lost a good deal of weight. He was 5 ft. 10½ in. in height and only weighed 9 st.; in 1892 he weighed 11 st. On pressing down the tongue a pinkish blue swelling the size of a Tangerine orange was seen. Laryngoscopically the vocal cords and glottis were quite free, and the tumour, apparently sessile, was seen to spring from the free edge of the epiglottis. Thinking it was probably a simple retention cyst (as no record of a solid tumour in this situation had come under his notice), Dr. Lodge punctured it with a medium-sized triangular keratome, when alarming hæmorrhage occurred. The edges of the puncture were seized with a pair of Mackenzie's laryngeal forceps, but as this did not stop the hæmorrhage the wire snare was passed over the tumour, and with this as a guide a silk ligature was put round the tumour below the puncture and tied. This checked the hæmorrhage, but next day it recurred, and the patient was sent into the Halifax Royal Infirmary, under the care of Dr. Priestley Leech. On the 12th the patient spoke in a tone of low nasal character; there was no cough, respiratory stridor, or enlarged glands in the neck. The breath had an offensive odour and the tumour was found to be covered with a muco-sanguinolent discharge, but there was no hæmorrhage. The rest of the organs were normal. As the patient was in a weak state operation was postponed until the 19th. As Dr. Leech had had no previous experience of growths in this situation he wrote to Sir Felix Semon to ask his advice whether sub-hyoid pharyngotomy would not be the best method of procedure. He kindly replied and said that either this method or removal through the mouth by the galvano-caustic loop appeared to him to be the most suitable. In order to avoid as far as possible the chance of any hæmorrhage, either primary or secondary, Dr. Leech decided to remove it by sub-hyoid pharyngotomy. As the patient could not lie down, either on his side or on his back, tracheotomy was done with the patient in the sitting posture after the subcutaneous injection of three-quarters of a grain of hydrochlorate of cocaine. The patient said he felt no pain. A Hahn's tube was introduced, and after waiting a quarter of an hour for the sponge to swell chloroform was given through a funnel connected with the Hahn's tube. The sponge, however, had not swollen sufficiently, and the patient breathed for the most part through the mouth, so that chloroform was given by both ways. The sponge swelled more and sub-hyoid pharyngotomy was done. The tumour was found to be attached to the tip of the epiglottis by a flat thin pedicle three-quarters of a inch wide. The tumour was brought out through the wound and the epiglottis, with the glottic folds, clamped; the tumour was removed along with the tip of the epiglottis. Two or three vessels were tied and the clamp removed. Very little blood was lost during the operation. The tumour measured one and a quarter inches wide, one and a quarter inches long, and three-quarters of an inch thick, with a pedicle nearly three-quarters of an inch wide. The wound was sewn up with fine catgut, with silkworm gut sutures for the skin; the Hahn's tube was removed, and the tracheotomy wound dusted over with iodoform and covered with gauze. The patient recovered well from the operation, and went on very comfortably during the rest of the day. No food was given by the mouth, but he was fed by nutrient enemata. In the evening there was some increase in the pulse and respiration rates. On the 18th the patient in the afternoon became somewhat restless and a fœtid smell was noticed from the mouth. The wound looked well. The restlessness increased, and he fell out of bed during the night. The pulse-rate rose to 138 and the respiration rate to 50 per minute, in spite of hypodermic injections of strychnia, rectal injections of coffee and brandy, and the patient died at 6.50 A.M. on the 19th from cardiac failure.

Necropsy.—Permission for a limited post-mortem examination only was obtained with some difficulty. The lungs and heart only were examined. The heart muscle was pale and flabby, but the valves were normal. The lungs were healthy, with the exception of an old cicatrix, with some adhesions at the right apex. A piece of the tumour was sent to the Clinical Research Association, and Mr. Targett reported as follows: "This tumour shows very little on microscopic examination; one can only suggest that it is a polypus composed of vascular fibro-cellular tissue which has become much distended by extravasated blood. There is no evidence of malignant disease in it."

Remarks by Dr. PRIESTLEY LEECH.—The above case is interesting on account of the rarity of the disease, and also because the operation—which is not a very common one—was followed by a fatal termination. This was a great disappointment, and the exact cause is not very clear. Personally I feel inclined to attribute it to the shock of the operation following so closely on the considerable loss of blood. I regret having performed the operation so soon after the hæmorrhage, but the patient wished it to be done as soon as possible, and it was feared a recurrence of the bleeding might take place. Sir Felix Semon drew my attention to the fact that in his series of cases published in THE LANCET of Dec. 15th and 22nd, 1894, the only patient who underwent sub-hyoid pharyngotomy died from some not fully

Digitized by Google

explained cause. The mental tension of the tracheotomy under cocaine may have had something to do with the fatal issue, though the patient said he felt no pain while it was being performed. From the experience of this case I think many operations might be performed under cocaine if anæsthesia by ether or chloroform is considered dangerous. As regards the operation itself, it is not difficult to perform, and it gives a splendid view of the epiglottis and the upper part of the larynx.

Reviews and Notices of Books.

Forensic Medicine and Toxicology. By C. O. HAWTHORNE, M.B.Glasg., Lecturer on Materia Medica and Therapeutics, Queen Margaret College, University of Glasgow. Second Edition. Glasgow: A. Stenhouse. Pp. 174. 1897.

THIS work is essentially a manual for students. The recognised facts and principles of forensic medicine, as defined by acknowledged authorities, are here classified and arranged with the object of assisting students engaged in preparing for examination. Such being the aim of the author, he has well succeeded in his endeavours. The book can hardly take the place of larger treatises, as it is a bare statement of facts, but as an aid to students immediately before presenting themselves for examination it would be valuable. All the principal points are selected and clearly enunciated. The section on wounds is particularly well worked out. From a medico-legal point of view the consideration of injuries from mechanical violence, however inflicted, is a very difficult and often complicated problem, and the chapters dealing with this subject in most of our leading text-books on forensic medicine are so involved that the student despairs of ever understanding the numerous traps and pitfalls which await him, should he be called on to testify to the causal relationship of wounds on an injured person or dead body. Dr. Hawthorne, however, has succeeded in placing before the student a concise and clear description of the main points which are involved and to which close attention should be given, and we believe that students will be more easily able to satisfy the examiners who question them on wounds after a study of this section than from the more lengthy descriptions usually found in the larger text-books.

The part of the book dealing with toxicology is also good from an examination point of view. Only those poisons are considered upon which questions are likely to be asked in examinations, others, such as cocaine, which may be met with in practice are omitted.

As an aid to the student preparing for examination we cordially recommend the book.

La Désarticulation Coxo-fémorale. Par le Dr. LOUIS CORONAT, Ancien Externe des Hôpitaux de Paris. (Amputation at the Hip-joint.) Paris: Asselin et Hougeau. 1896. Pp. 104.

AMPUTATION at the hip is probably the most severe operation to which the human body is submitted, and the high mortality which accompanies it makes it a subject well deserving of careful study. Lacroix, of Orleans, though by no means the first to suggest the operation, was the first to carry it out, for in 1748 he amputated at both hips in a boy, aged fourteen years, for gangrene from ergot. An interval of only four days separated the operations, yet the patient survived the second amputation eleven days. In 1773 the first successful case occurred in the practice of Pérault, of St. Maure, who performed the disarticulation on a man, aged thirty-one years, for severe traumatism of the thigh. The operation became a recognised form of treatment, but failures far outnumbered successes, and, in fact, in many series of cases all died; for instance, even so late as in the Franco-German war of 1870 Von Langenbeck records twenty-three deaths in twenty-three cases. A very instructive treatise on the subject was written by Lüning in 1877, in which he gave statistics of 239 cases which he had collected. Of these 5 per cent. died during the operation, 12 per cent. within one hour, and 46 per cent. during the first day.

There are two chief causes of death after amputation at the hip-joint, hæmorrhage and sepsis, and the former is probably by far the more important. The number of methods suggested for disarticulation is very large, but Dr. Coronat considers that the operation may be satisfactorily performed in two ways, one of which the author calls the operation of Ravaton-Veitch, and the other the operation of Verneuil. The first is practically that which in England is usually called the Furneaux-Jordan method, though, as Dr. Coronat points out, it was first described by Ravaton in 1768. It consists in amputating through the upper third of the thigh and then disarticulating by an external incision. In this method the vessels are cut chiefly near their endings, and the hæmorrhage is comparatively slight. In the second method the hæmorrhage is controlled by tying the femoral vessels before cutting those flaps which may be most convenient in the particular case. Dr. Coronat's statistics indicate that for non-traumatic cases the mortality of the second method is more than double that of the first. The author considers that the method of Ravaton-Veitch should always be employed, unless the upper third of the thigh has been attacked by the disease for which the disarticulation is to be performed. A copious bibliography is appended, and statistics of all recorded cases since 1880 are given. The improvement in the statistics of the operation due to the better control of hæmorrhage and the practice of antisepsis is very striking. In 1877 Lüning's statistics gave a mortality of 70 per cent. In 1888 Eisenberg gives 52 per cent., and Alvernhe gives 44 per cent., while according to the author's statistics of cases operated on since 1880 the mortality has fallen to 29·3 per cent.

We have read this treatise with great interest, for it is most scholarly, careful, and complete.

A Treatise on the Surgery of the Alimentary Canal. By A. ERNEST MAYLARD, M.B., B.S. Lond., Surgeon to the Victoria Infirmary, Glasgow. &c. Pp. xxiv.-724. London: J. & A. Churchill. 1896. Price 25*s.*

THE growing importance of the surgery of the alimentary canal naturally leads to the publication of special treatises dealing only with this portion of the body, and we gladly welcome Dr. Maylard's work as a very successful attempt to give in one volume the whole of the surgery of the stomach and intestines. There is a unity in the alimentary canal which renders it specially suitable as a subject for a special treatise; its morbid conditions and the symptoms to which they give rise are so important that they demand a careful study. The author has decided not to deal with the diseases of the mouth and pharynx, though these form no unimportant part of the alimentary canal; the anus also is excluded, and thus hæmorrhoids and fistula in ano are not mentioned; the whole subject of external hernia also is purposely omitted, yet, though so much has been left out, there has been ample material to fill more than 700 pages. Of course, a treatise covering so extensive an area of surgery must give occasion for many differences of opinion, but we must acknowledge that we have not succeeded in finding any statement from which we wish to express our dissent. Dr. Maylard has adopted the practice of illustrating each important injury or disease by the description of a particular case culled from his own practice or from that of others; in all 116 cases are described; thus a much more vivid impression is made on the mind of the

Digitized by Google

reader. This custom, though easily carried to excess, is, we are inclined to think, not so common as was formerly the case; this is to be regretted, as it is of great value, and certainly constituted one of the great charms of that classical work, Sir Thomas Watson's Practice of Physic. It would extend this notice far beyond the limits of our space even to mention all the matters dealt with in this volume, but an idea may be formed of the thoroughness with which the subject has been treated if we consider the description the author gives of intestinal anastomosis. Dr. Maylard first points out that there are three ways in which it may be effected—namely, end-to-end anastomosis, lateral anastomosis, and lateral implantation; in the last the end of one piece of bowel is joined to the side of the other portion of intestine. A description then follows of the various methods of suturing bowel, the Lembert and the Czerny-Lembert sutures, those devised by Wölfler, Bishop, Abbe, Maunsell, and Halstead; then come Senn's plates, Paul's tube, Robinson's rubber tube, Mayo Robson's bone bobbins, and Murphy's button; and each of these is fully described and illustrated. The illustrations contained in the work are decidedly good, many being reproductions of photographs. Copious indices of names and subjects conclude the volume. The writing of so full and accurate a treatise as this must have entailed great labour, but the work has been done well, and we can express unreservedly our favourable opinion of the volume.

LIBRARY TABLE.

Burdett's Hospitals and Charities, 1897; being the Year-book of Philanthropy. By Sir HENRY C. BURDETT. London: The Scientific Press, Southampton-street, Strand, W.C. Price 5s.—This excellent volume, of over 1000 pages, contains a vast amount of information, some of which is sure to be needed at some time or other by every practitioner. The introductory chapters are especially valuable, facts and figures in connexion with hospitals and charities being dealt with in a manner which is characteristic of Sir Henry Burdett. The large amount of labour involved in the preparation of this hospitals' and charities' "Whitaker" is a monument to the ability of its compiler.

Plumbing, House Drainage, &c. By WILLIAM PATON BUCHAN. Seventh Edition. London: Crosby Lockwood and Son. Price 3s. 6d.—Whatever tends to the improvement of the practical ability or technical knowledge of those who undertake the work of the plumber is a factor in the diminution of the death-rate. As such, this manual is sure of a welcome, but the combination of a trade catalogue with a professed text-book on plumbing, as in this instance, must fail to commend it to general approval. It is to be regretted that the late Mr. Buchan, who is well known to have done much useful work for the advancement of sound plumbing, allowed the book to be issued in its present form. Had it been condensed and judiciously edited its value would have been materially increased; as it is, some excellent work is obscured by a quantity of matter that might well be spared.

The Fairies' Favourite; or, the Story of Queen Victoria told for Children. By T. MULLETT ELLIS. London: Ash Partners, Limited. 1897. Pp. 56. Price 1s.—This little book deserves a passing notice among the immense amount of literature to which the Jubilee celebrations have given rise. It is, at the title indicates, a child's story-book in which many of the leading events of the Queen's life are interwoven with fairy tales and presented in a "popular" form. The narrative is interspersed with nursery rhymes; the cover is ornamental.

Medical and Surgical Report of the Presbyterian Hospital in the City of New York.—Edited by ANDREW J. MCCOSH, M.D., and WALTER B. JAMES, M.D. New York: Trow Directory Printing and Bookbinding Company. 1897. Pp. xiv. and 272.—Dr. W. Gilman Thompson and Dr. J. P. Thornley contribute articles on Cold Tub-bathing in Enteric Fever Based upon an Extended Experience of the Disease (upwards of 200 cases). If the moribund cases and those which had hæmorrhage or pneumonia before admission be deducted the mortality was between 7 and 8 per cent. Whenever the patients' rectal temperature reached 102·5° F. they were immersed in water at 70° for fifteen minutes, during which time they were vigorously rubbed by the nurses; if at the expiration of three hours the temperature was again above 102·5° another bath was given. Dr. F. Tilden Brown describes some cases of renal tuberculosis, and gives a valuable and copiously illustrated review of the whole subject; the list of works (mostly German) to which he makes reference fills five pages. Dr. N. R. Norton contributes a report on cases of sunstroke during the summer of 1896. On the six days from Aug. 8th to Aug. 13th inclusive about 110 persons were brought to the hospital suffering from the heat. With fifty the symptoms were comparatively mild, but with sixty-one, among whom there were nine deaths, the temperature was 104° or higher, including twelve whose temperatures varied from 110·1° to 115°.

JOURNALS AND REVIEWS.

THE *Practitioner* for August naturally gives up a good deal of the space devoted to editorial matter to subjects connected with the forthcoming medical congresses. Of the original communications, perhaps the most interesting is that by Dr. F. J. Shepherd, the lecturer on Operative Surgery at McGill University, upon the Surgery of Bronchocele. Dr. F. G. Finlay and Dr. W. I. Bradley, of the Montreal General Hospital, report a case of that excessively rare disease, primary sarcoma of the pleura; and Dr. R. C. Kirkpatrick, of the same hospital, a case of perforated gastric ulcer successfully treated by operation. Mr. Christopher Heath supplies an eminently practical clinical lecture upon Epithelioma and Rodent Ulcer, and Dr. Herman Weber writes upon Health Resorts and Waters for the Anæmic. The Hero of Medicine for the month is Benjamin Rush, the great physician of Philadelphia in the eighteenth century. The Medico-Literary Causerie deals with what was perhaps the most degrading of the many follies of fashionable society at the Court of Louis XIV.—namely, the rush of courtiers to have some operation on the anus performed because Le Roi Soleil had a fistula cut.

Birmingham Medical Review.—Dr. Arthur Foxwell gives a description of Llandrindod, Llangammarch, and some other spas of Mid-Wales. Mr. Lawson Tait continues from the May number the discussion of the question, Was Robert Houston, of Glasgow, the First Ovariotomist? He of course replies in the affirmative as before, and fortifies himself with a letter from Dr. Emery Lamphear, of St. Louis, editor of the *American Journal of Surgery and Gynæcology*, who wrote: "With much pleasure I have read your remarks upon Robert Houston's case; I quite agree with you in every particular. One of my latest ovariotomies was of exactly the kind you describe. It gave much trouble in emptying the abdomen; there was no pedicle, nothing but shreds." This paragraph is accompanied by a short article from the pen of the late Mr. J. Greig Smith, of Bristol, who, without entering on a criticism of the operation performed by Houston, seems to ridicule the opinion that it was an ovariotomy.

Analytical Records
FROM
THE LANCET LABORATORY.

NON-ALCOHOLIC MALT LIQUORS.
(MALTOP AND CO., THE BREWERY, ACTON.)

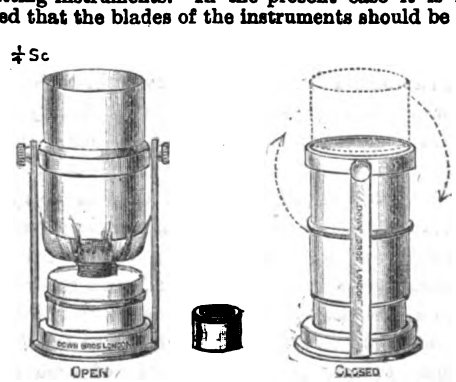
IT is somewhat interesting in connexion with these beers to find that the same plant and apparatus formerly used in the brewing of ordinary ale is now employed with marked success in the preparation of the non-fermented, and consequently non-alcoholic, beers about to be described. The samples received, and the analytical results they yielded, were as follows:—Mild ale: extractives, 4·26 per cent.; mineral matter, 0·18 per cent.; alcohol, by weight 0·05 per cent., by volume 0·07 per cent., equal to proof spirit 0·12 per cent.; total acidity reckoned as acetic acid, 0·22 per cent. Nourishing stout: extractives, 5·09 per cent.; mineral matter, 0·20 per cent.; alcohol, by weight 0·32 per cent., by volume 0·40 per cent., equal to proof spirit 0·70 per cent.; total acidity reckoned as acetic acid, 0·34 per cent. Lager beer: extractives, 4·15 per cent.; mineral matter, 0·25 per cent.; alcohol, by weight 0·05 per cent., by volume 0·07 per cent., equal to proof spirit 0·12 per cent.; total acidity reckoned as acetic acid, 0·27 per cent. India pale ale: extractives, 4·41 per cent.; mineral matter, 0 22 per cent.; alcohol, by weight 0·05 per cent., by volume 0·07 per cent., equal to proof spirit 0·12 per cent.; total acidity reckoned as acetic acid, 0·28 per cent. Double stout: extractives, 5·62 per cent.; mineral matter, 0·14 per cent.; alcohol, by weight 0·32 per cent., by volume 0·40 per cent., equal to proof spirit 0·70 per cent.; total acidity reckoned as acetic acid, 0·28 per cent. The lager beer is prepared from Bavarian hops and malted barley. The process consists in the mashing of malt as with the ordinary brewing procedure, but the malt sugar thus produced is not allowed to undergo any fermentation. The liquor is then bittered with hops and finally aerated. Thus these beers present exactly the composition of ordinary brewed beers without the alcohol. As the foregoing analyses show, the samples were practically free from alcohol even when reckoned as proof spirit. They may be regarded as genuine hop and malt liquors prepared on approved scientific lines, and of a wholesome character. We found no objectionable preservatives and the flavour was decidedly like that of beer, with a delicate bitter and pleasant malty flavour. It should be added that the water-supply is derived from an artesian well 500 ft. in depth, the quality of which is free from reproach, and at the same time well adapted for brewing purposes.

"VARALETTES."
(ALFRED BISHOP, LIMITED, 17, SPECK'S FIELDS, MILE END NEW TOWN, E.)

"Varalettes" is a distinctive term applied to effervescent tablets, which present in an agreeable and satisfactory form certain medicaments. Foremost we think in interest amongst these is the "varalette" containing piperazine citrate. Piperazine in this form possesses some distinct advantages, since this salt is constant in composition, containing always three molecules of piperazine to two molecules of citric acid; further, it is a neutral salt non-volatile and non-hygroscopic while in the form of citrate, piperazine does not lose its solvent power over uric acid, and moreover leads to no objectionable products of oxidation in the system. "Varalettes" are also prepared containing antipyrin with and without caffeine, lithia bitartrate, lithia citrate, with and without potassium citrate, potassium iodide, and urotropine. They are a very convenient and pleasant form of medicament, yielding a perfectly clear and effervescent solution when dropped into water. "Varalettes" are contained in bottles suitable for placing in the waistcoat pocket.

HOMO BREAD.
(M. AND C. WEST, ASHBURNHAM BAKERY, 48, LOT'S-ROAD, CHELSEA, S.W.)

The process by which this well-baked loaf is prepared is evidently directed towards securing a maximum proportion of the real nourishing constituents of wheat. It contains the germ of wheat, while all irritating branny particles are absent. The loaf proved to possess a good wheaten flavour and presented a good texture.



OLD BRANDY.
(GAUTIER FRÈRES, COGNAC.)

The sample of spirit submitted to us was described as "very fine liqueur brandy twenty years old," so that it was manufactured just a year before the phylloxera ravaged the Cognac district. The brandy has a fine mellow taste, and possesses that peculiar fragrance characteristic of a well-matured and genuine grape spirit. The figures of analysis were as follows:—Alcohol, by weight 36·67 per cent., by volume 43·69 per cent., equal to proof spirit 76·56 per cent.; total extractives, 1·20 per cent; total acidity, 0·06 per cent. It will thus be seen that the alcoholic strength is somewhat low, the extractive matter somewhat in excess (the colour also being decidedly dark), while the acidity is practically *nil*; but these are all facts tending to confirm the age and origin of the spirit. It is well known that since the unfortunate devastation which overtook the French vineyards in the Cognac district in 1878 a large quantity of spurious Cognac brandy has been imported into England. As the consuls' reports have shown, this shipment has far exceeded the possible output of grape spirit. We believe the specimen before us is genuine Cognac brandy and part of what must be a small quantity yet left. It may not be generally known that excellent grape spirit can be obtained if desired, and this should be preferred to the stuff which is distilled from maize and other cereals. The product before us, being a genuine grape spirit and possessing those estimable characters in regard to aroma and flavour of real Cognac brandy, is peculiarly well adapted for medicinal purposes.

New Inventions.

NEW PORTABLE EYE INSTRUMENT STERILISER.

THE illustration represents a new portable form of steriliser for eye instruments designed at the suggestion of Mr. Simeon Snell of Sheffield. With the ordinary forms of steriliser the instruments are frequently immersed too long in the boiling water, which results in injury to the edges of the cutting instruments. In the present case it is merely intended that the blades of the instruments should be dipped

in, but it is large enough to allow of the immersion of a speculum and other instruments if desired. The whole apparatus is so portable that it can be easily carried to the patient's house in an ordinary surgeon's bag. The apparatus is made by Messrs. Down Bros., 21, St. Thomas's-street, London, S.E.

THE LANCET.

LONDON: SATURDAY, AUGUST 14, 1897.

WE have from time to time in these columns insisted most strenuously that some means should be provided whereby antitoxins supplied for the treatment of diphtheria and tetanus, especially the former, should be tested and standardised before passing into the hands of those who are to use them. We first drew attention to this matter in a series of comparative investigations which were undertaken by THE LANCET Special Commission on the Relative Strengths of Diphtheria Antitoxic Serums,[1] and the results then obtained formed a basis for comparison of the various serums at that time in the market. We took the opportunity of drawing special attention to the necessity for the appointment of some central authority, similar to the State Institution in Germany, founded for the definite purpose of testing and controlling the serum sent into the market. Although we strongly urged that the State, through the Home Office or through the Board of Trade, should undertake this work, we were fully aware of the difficulty of converting the official heads of these departments to our way of thinking, and Mr. CHAPLIN, in answer to Mr. HARRY SAMUEL, maintained as a reason for his non-intervention that the department of which he was the official head had only to do with the prevention of the disease and not with its treatment. The Home Office appears to have adopted a similar attitude, for it is now over twelve months since we first drew attention to the subject, and nothing has been done. Fortunately, however, there are public bodies who are fully at one with us in appreciating the importance of having a common standard for, and control of the strength of, antitoxins.

There can be no doubt that, partly as the result of our action in this matter and partly owing to improvements in the methods of production of antitoxin, there has been a marked rise in the antitoxic value of the serum that has been put on the market in this country, which may now be held to compare very favourably with the antitoxic serum prepared abroad. In fact, with the exception of the strongest forms prepared in the German laboratories, it may be said to be equal to any on the market. This is a most satisfactory outcome of our protest—for protest it was—that the serums obtained in this country were not only of comparatively low antitoxic value, but that they differed very greatly from one another, and were not sent out, even from the same establishments, of constant strength, with the result that as there was no strength marked on each sample bottle the practitioner was left in grave doubt as to the dose to be administered and the antitoxic value of each dose sent out. We believe that most of these objections have now to a great extent been removed, but there still remains the fact that no official comparison of the various serums is at present available, and we therefore look upon it as very satisfactory indeed that the Royal Colleges of Physicians of London and Surgeons of England are making arrangements to test any antitoxin that may be sent to them, and to send out with such antitoxin a certificate of strength and purity. Even now from time to time we receive queries as to which serum is the best, which contains the greatest number of units in a definite quantity, and which has been found to give the best results. Now that there is the prospect that a central authority will take the matter up there should be no difficulty in obtaining this information, and medical practitioners will be satisfied that all antitoxins with which a certificate is sent out have been standardised in the same way, and that therefore a knowledge as to the relative number of units contained in a given quantity of different samples of serum may be arrived at by a simple comparison of certificates.

It may be argued that the preparation of antitoxin has improved so much that it is now unnecessary to have such accurate central control. It has been found, however, even in Germany, where there has been such long experience of the manufacture and testing of antitoxin, that differences of opinion are constantly arising between those who manufacture the antitoxin and those with whom rests the control under Government, and it is only the fact that all the serums must pass through the hands of Professor EHRLICH and his assistants that keeps the relative, and approximately the actual, strength of the antitoxic serums at a constant level. That the process of testing is not by any means a simple one is now fully recognised, and Professor EHRLICH, who has been working at the subject for the last four or five years, has only recently published a method differing very materially from his original method, by means of which he is able to get more accurate and constant results than he has hitherto been able to obtain. It appears to be a comparatively easy matter to obtain accurate relative results in any single series of experiments where the same test-toxin standardised from time to time is used, and where exactly the same conditions of experiment are adhered to; but the difficulty hitherto appears to have been the maintenance of the same standard where fresh test-toxins have to be obtained. Professor EHRLICH, by the application of his new method and by careful selection of his test-toxins, seems to have overcome some of the difficulties that up to the present have stood in the way of those engaged in testing antitoxic serums, and it is now possible to determine, not merely the relative, but the actual, strengths of antitoxic serums with a fair degree of accuracy, so that, with the allowance for an error of from 5 to 10 per cent., every serum should be up to the strength that is claimed for it by the manufacturers.

It will be remembered that in our report we stated that the relative strengths of antitoxins was generally indicated, but that it should be distinctly borne in mind that the standard used was an arbitrary one, and that the results obtained might not be absolutely correct; but our Commissioners went on to say: "The astounding variation in the quality of the serum supplied by different makers and the puzzling way in which the antitoxin from certain sources varied from time to time" were constantly making themselves evident and "that the results

[1] THE LANCET, July 18th, 1896.

Digitized by Google

obtained by the use of these serums in the treatment of diphtheria should have varied is what must be expected if the antitoxin does exert any influence at all in the course of the disease. It is, under these circumstances, we think, intolerable that the medical man should be kept in ignorance of the strength of the serum which he is making use of, when the want of such knowledge may be but too often a matter of life or death to his patient." Of course, this criticism does not now apply to anything like the same extent that it did when it was made, but there is still evidence that there is a real necessity for a comparison of the serums that are made. The adoption and extension by the Royal Colleges of Physicians and Surgeons of a plan that we so strongly insisted upon does not remove the necessity that each maker of antitoxic serum should take every means of ensuring the accuracy of his own tests, but we are convinced that medical practitioners will hail with satisfaction a second control, especially in so far that it is not in any way in the hands of those who are producing antitoxic serum for sale; and we congratulate the Colleges on the fact that they have taken such an important step with the object of inspiring confidence in a therapeutic or physiological agent that has already contributed materially to the mitigation of the horrors attendant upon diphtheria.

THE subject of the Croonian Lectures[1] lately delivered before the Royal College of Physicians of London was one upon which the lecturer, Dr. HALE WHITE, could speak with authority. His contributions to the solution of the problems of pyrexia have been many and fruitful, and the particular questions dealt with in these lectures were handled with becoming modesty and in the true spirit of scientific candour. At all times interesting, the subject of pyrexia is yet one of the most difficult to investigate and to satisfactorily explain. The phenomena of the condition have been studied from every point of view, but too often conclusions have been reached which are hardly warranted by the data supplied, and it is not a little remarkable that in spite of all that has been done so much uncertainty should still prevail regarding the intimate nature of the changes at the root of the process. It is true that there is general agreement as to the physiological mechanism governing the production and regulation of animal heat, but the application of general physiological principles to the explanation of pathological phenomena is often not so simple as it seems. We may assume, for instance, that the derangement of the normal mechanism excited by pyretogenetic agents may depend on disturbance of the thermotaxic control of the nervous centres, and facts may be cited to prove how such disorder is adequate to the production of pyrexia. On the other hand, it is equally possible to explain pyrexia by reference to an abnormally excited production of heat or, conversely, to a diminished loss of heat from the body by conditions of cutaneous circulation or of deficient activity of sweat glands. Theoretical surmises do not, however, stand on the same level as proven facts; and they may be not only erroneous but very misleading. It is the merit of these Croonian lectures that they are practically limited to an exposition of observed facts; for that very reason they do not offer much ground for comment, whilst they add considerably to the store of knowledge of, and indicate the lines to be pursued by, investigators on those questions.

Dr. HALE WHITE is to be commended for the caution which he has exercised in dealing with the subject. He opened his lectures by adverting to certain fallacies which may vitiate the application of the results of experimental research; whilst his third lecture, which dealt mainly with calorimetry, contained a candid admission that the methods as yet available (which he himself has done much to improve) do not permit any very definite conclusions to be drawn from this line of inquiry. Perhaps the most instructive portion of his lectures was that which dealt with the question whether the production of heat is increased in fever. It was prefaced by an interesting demonstration that the specific heat of a hybernating animal is almost the same as that of the dead tissues, and it was inferred that more calories are required to raise the temperature of the body one degree in pyrexial than in apyrexial states. By a comparative study of the surface temperature and internal temperature of the body and the estimation of the activity of sweat glands under varying circumstances, it was clearly shown that the conditions which raise the temperature of the body operate in different ways. Thus, the effect of the hot bath and of the Turkish bath in raising the temperature of the body is due to the arrest of loss of heat, the restoration to the normal being effected mainly by the excessive sweating which follows the bath. The effect of cerebral injury in raising the internal temperature was shown to be due to an excitation of thermogenesis, for a lesion of the corpus striatum was accompanied by a rise of temperature on the paralysed side in spite of the more active production of sweat on that side. The same line of comparative observations made in various febrile states showed that these do not always depend on the same kind of disturbance. Thus, in typhoid fever the loss of heat by sweating was found to be small, so that this diminished thermolysis as well as the increase of thermogenesis may operate to produce the febrile condition in that disease. In pneumonia the surface temperatures indicated a considerable loss by radiation and conduction, the inference being that the high internal temperature is due to greatly increased production of heat, whilst the abundant sweating which ensues on the crisis serves to keep down the temperature after the febrile process has run its course. In erysipelas, similarly, the evidence of loss of heat being increased during the fever necessarily implies that this latter must be due to greatly increased internal production of heat; whilst in suppuration the rise of body temperature must be in part due to diminished loss of heat. The sweating associated with pulmonary tuberculosis doubtless mainly accounts for the remission of temperature characteristic of that disease. These observations in pathological states were supplemented by others made in health, during and after exercise, which showed that the rise of temperature due to the latter was controlled by excess of heat loss, but that the degree of accommodation varies in individuals.

After referring at length to the evidence afforded by

[1] THE LANCET, June 19th and 26th and July 3rd and 10th, 1897.

Digitized by Google

calorimetrical observations—a line of inquiry that should yield much valuable information upon the subject of thermogenesis, but which, as Dr. HALE WHITE pointed out, is not yet sufficiently free from error to be exact—he proceeded in his fourth lecture to discuss the evidence afforded by chemical investigations. The heat-values of articles of diet have been estimated and the amount of heat represented by the amounts of nitrogen and carbon excreted have been calculated, with the main result that in fever proteid metabolism is the chief source of heat production. A pregnant fact is that this destruction of proteids and fats is lessened by administration of grape-sugar, for this can be of service practically as suggestive of a means for preventing excessive waste of tissue in fever. The highly interesting subject of the relations between fever and the micro-organisms which mostly are responsible for exciting it was touched upon towards the close, and facts were stated which seemed to favour the notion that the fever process is really a means of defence against these organisms. That antipyretic drugs have not done what was expected of them seems to be generally admitted, whilst those remedies which do seem to control fever and also improve the condition of the patient are just those which have a directly antagonistic effect on the toxic agent—e.g., quinine in ague, mercury in syphilis, and salicin in acute rheumatism. It is, however, less obvious that drugs which have the power of exciting fever would be practically useful in checking the toxæmia induced by the invasion of micro-organisms, although the question is not so paradoxical as it appears to be. It must not be forgotten that the increased temperature is of itself likely to injure the body, and that in its most vital parts, so that although it may be true that the efficacy of the cold bath in the treatment of typhoid fever is to be ascribed to its action on the nervous system and not to its antipyretic influence, the very fact that the fever is lessened does *pro tanto* diminish the liability to myocardial and other degenerations that constitute one of the most real dangers of the disease. It might, of course, be argued that such changes depended on the toxin itself, and were, therefore, only accidentally associated with the pyrexia; but it is, nevertheless, a clinical fact that the liability to such degenerations of tissue has been markedly lessened under this line of treatment.

A REPORT for the year 1896–97 which was recently issued by the National Society for the Prevention of Cruelty to Children contains much that is, and ought to be, of public interest. During this period the scope of the Society's operations has been much extended. The number of its local committees has increased by 109. The total number of cases investigated has risen from 20,739 to 23,124. Its income is likewise greater by £7756, though this addition has not sufficed to cover a still greater expenditure incurred by its widening sphere of activity, the net result being a deficit of £3178. It is satisfactory to note that its necessarily costly labours have not been wanting in returns of very practical utility. Parochial guardians, clergy, tradesmen, school-teachers, and departmental committees of unions are quoted in evidence of the fact that a new and improved order of domestic life has arisen within the area of its supervision since that began. This fact is further indicated by the simple and instructive chart of its results which has been published by the Society. By this means is shown at a glance the progress made by its efforts during the twelve years of its existence. We note in particular a marked decrease in the number of violent offences against children, which has diminished by more than half. Street offences have also steadily decreased. Neglect constitutes the form of cruelty to children which is now most common, and of its existence there is still abundant evidence.

The cost of preventive treatment per case, we are pleased to note, has much diminished, having fallen from £2 8*s.* 1*d.* to 17*s.* 6*d.* This point derives a special interest from the fact that the past year has witnessed the culmination of a series of attacks mainly directed against the financial administration of the Society. In consequence of these attacks it was decided by the central committee of the Society to institute an inquiry into the Society's acts and *modus operandi*, and the conduct of this inquiry was entrusted to the hands of Lord HERSCHELL and two assessors, Mr. VICTOR A. WILLIAMSON, C.M.G., and Mr. FRANCIS W. BUXTON. It is needless to say that this investigation was thorough and exhaustive. The amount of ground covered by it was also very great. Its results may, therefore, be regarded as being for all practical purposes conclusive. Of these, viewed with reference to their main issues and their collective significance, we can safely assert that they have cast no slur upon the character, purposes, or management of the Society. On the contrary, they bear testimony to the great necessity for its existence, its value as an aid to the legal safeguards of childhood, the integrity and zeal of its officials, and the deserved success of its efforts. It would be remarkable if an examination so searching as this could detect no possibility of improving existing methods in the case of so young a society, but the suggestions made in this sense by the members of the committee of inquiry must be regarded rather in the light of advice than of censure, and as such they are, for the most part, evidently intended. The system of centralisation maintained by the Society has their entire approval, and they propose to render this more effective by allowing a judicious increase of responsibility to branch committees. They are of opinion that a budget estimate of probable income and expenditure should be published annually as a guide for contemplated operations. They consider that the outlay on publications for supply to branches has in some cases been in excess of the demand for it, and they advise retrenchment in this direction, especially now that the work of the Society is more generally known than formerly. At the same time, they admit the difficulty of arriving at an exact estimate of the amount required. So, likewise, they recognise the occasional necessity for what might seem excessive outlay on police prosecutions, while they think that as much as possible of this duty should now be entrusted to the public authorities. Outlay on shelters they believe to be less needful than it was prior to the year 1894, when the charitable powers of parochial guardians were increased, and to this view they have the consent already expressed in the practice of the Executive of the Society. They do not concur in objections which have been raised

Digitized by Google

against the expense of office rents, salaries for the staff and inspectors, occasional entertainments for the latter, and certain alleged gratuities. The control exercised by the financial committee they consider to have worked well, but they advise a greater strictness in its methods as calculated still further to secure the Society against the possibility of abuses. They also advise a more precise regulation of travelling expenses, though they do not find that any great loss, if any, has occurred to the Society under this head in the past.

Two clauses from the published report of the investigation may be quoted here: "We believe that the committee and the officials of the Society in the work which they have done for it have been actuated only by a desire to further its interests and to promote a work which they believe to be useful and beneficent;" and "we are far from deprecating criticism of the finances and proceedings of a society administering charitable funds, we think it has a stimulating and healthy effect ..... but it would be a cause for regret if it had the effect of causing funds to be withheld and thus crippling the action of a society which is doing useful work and which would but for its action be left to a great extent undone."

THE recent meeting of the Council of the Metropolitan Hospital Sunday Fund (an account of which will be found in another column) was of more than usual interest. The circumstances of the year have been altogether exceptional, and withal such as to make the members of the Council somewhat anxious as to the success of the Fund. The great effort of H.R.H. the PRINCE of WALES to raise enough money to exonerate the hospitals of London from debt and provide an annual sum that would save them from future differences between receipts and expenditure, a hundred other claims in connexion with the commemoration of HER MAJESTY'S sixty years of reign, and many exceptional appeals to public generosity, have combined to compete with the Hospital Sunday Fund and other annual sources of hospital income. It is most gratifying to have to report that these congenial but as the result showed slightly competitive claims have only served to prove the strength of the hold which the Metropolitan Hospital Sunday Fund has on the confidence of the public. Sir SYDNEY WATERLOW was able to announce at the meeting that £40,000 had been received, an amount only a little below the receipts of an ordinary year, and allowing £39,705 to be distributed among 132 hospitals, 56 dispensaries, and other similar institutions. The result should stimulate the Council to still further energy in the use of their great position till the Fund reaches a sum still more proportionate to the wants of the hospitals. We can only express the hope that all other channels of ordinary hospital incomes will be equally successful in this memorable year. It will be no mean achievement if His Royal Highness should be able to say that he has raised an unprecedented sum for the hospitals of London without seriously entrenching on the ordinary sources of their wealth.

The receipt of money for hospitals is not the only function of the Council of the Hospital Sunday Fund. It has besides, and, indeed, in virtue of this function, another—viz., that of seeing that the hospitals and other institutions which it benefits are well and properly administered. In other words, it has to consider, not only the *needs*, but the *merits* of hospitals. The report of the Distribution Committee shows that its members are increasingly alive to this part of their duties. They point out that they have deemed it necessary to invite the attendance of a much larger number of the representatives of institutions than in former years. Officials from no less than thirty-eight institutions were invited to meet the Distribution Committee to explain matters in their accounts or in their administration which seemed to the committee to need such explanation. The result was a conference with the managers of thirty institutions, which was found to be "useful and mutually instructive." In some cases objections were removed or modified by the explanations; in others the objections do not seem to have been removed, and the committee was "only confirmed in its impressions." Such faithfulness on the part of the Distribution Committee will not only tend to correct errors of management and methods of administration which lower the public respect for the voluntary hospital system, but will raise the Distribution Committee and the Council in public estimation. Half the basis of the demand for a central hospital board would be removed if the Hospital Sunday Fund had been more faithful in the use of its duties as an advisory body, trusted by the public to administer its money for hospital purposes. Can anything be more obvious than this duty of the Council? We may take this conference with thirty of the hospitals as a proof, on the one hand, that they need a little friendly criticism, and, on the other hand, that the Council, through its awarding committee, will not shrink from its duties.

Several subjects were mooted in a cursory way which will doubtless receive more serious attention from the Council. One of these was the question of patients' payments—the light in which such payments are regarded by the Distribution Committee in making their awards. Are they to be encouraged or the reverse? Are they a merit or a demerit? Do they pauperise the patients or give them a proper sense of contributing to their own treatment? Do they raise or lower the estimate of medical service? Do they bring to the hospitals classes for whom they were never intended, and so exclude others for whom they were intended? Do they make the hospital a cheap dispensary and bring it into unnecessary competition with general practitioners in the humbler and more arduous branches of practice? These are grave questions raised chiefly by the Hon. SIDNEY HOLLAND and Sir HENRY BURDETT, and we can scarcely think that these gentlemen would regard them as disposed of in the short replies of Sir SYDNEY WATERLOW. We can only hope that the topic will be raised again for formal consideration by the Council. The question of St. Thomas's Hospital and its claim to a grant from the Council was raised indirectly by a complaint of Sir EDMUND HAY CURRIE that the south of London got so small a proportion out of the Fund and more directly by a question from Sir DYCE DUCKWORTH. Sir SYDNEY WATERLOW said, in reply, that there had been no disposition to refuse help to St. Thomas's Hospital, but that only lately had the treasurer of St. Thomas's Hospital

Digitized by Google

expressed willingness to send in the accounts to the Hospital Sunday Fund, which led him to hope that next year this great institution would receive a grant.

The important subject of out-patient abuse was raised by Dr. GLOVER, who showed from the statistics before the meeting that in 1896 the number of out-patients, so far from diminishing, was increasing. Taking fifteen of the principal hospitals, the statistics supplied to them showed an increase of nearly 20,000 as compared with the previous year. Dr. GLOVER was anxious to know when the Distribution Committee was going to give its report to the Council, as requested, on this subject. The answer of Sir SYDNEY WATERLOW was not unsatisfactory. He showed the many-sidedness of the question, and alleged that the committee had already met several times, but were anxious for still more evidence that they might present a report covering the whole subject. Such a report will, indeed, justify a delay of some eighteen months, and if valuable in proportion to the delay, as Sir SYDNEY WATERLOW promises, will do more to raise the amount of the Fund and the credit of the Council than anything it has yet done. We gladly recognise in Sir SYDNEY WATERLOW'S language indications that he and the Distribution Committee are beginning to realise the duty of the Council to grapple with this question and to guide public opinion in relation to it.

Annotations.

"Ne quid nimis."

"MEDICINE, PAST AND PRESENT, IN RUSSIA."

WE regret that, through an unfortunate inadvertency, in the article on the Moscow Congress in our issue of July 31st the portrait of the late Dr. Botkin (Fig. 3, p. 274) was described as that of Professor N. V. Skliffosowski. Similarly, in our supplement published last week, the portrait of Professor Skliffosowski (Fig. 13, p. 373) was labelled Professor S. P. Botkin. We can only express a hope that the error has not been the cause of any annoyance to the esteemed joint president of the organising committee of the Congress.

ALPINE ADVENTURE AND MISADVENTURE.

FROM Arosa, on the 8th inst., a "Holiday Contributor" writes:—"THE LANCET'S view[1] that, more likely than not, Mr. Cooper's disappearance is due to his having fallen into the Visp when overtaken by the senile vertigo or syncope not unnatural in a septuagenarian beside the rush and the roar of a mountain torrent is widely adopted by the Swiss press. The *Neue Zürcher Zeitung*, an ably conducted organ, prints a letter from Herr Albert Fleiner, in which that hypothesis is strenuously maintained as the only rational one, all the more that within short intervals of each other there have been three similar 'disappearances' due to drowning in the Visp, while a fourth case in the neighbouring Findelenbach was just saved from being a 'disappearance' by the opportune arrival of assistance from wayfarers. Of the three men who fell into the Visp the body of but one was ever recovered, and that only after months had elapsed. *Au reste*, the hypothesis of foul play is indignantly dismissed with the remark that Switzerland is not Calabria; that of the Italian workmen employed on the local railway only very few are now retained; and that those at the time of Mr. Cooper's disappearance must have been under effective observation. The season has, indeed, been a tragic one—less so, perhaps, than others, but still sufficiently so to justify the warnings from time to time sounded in THE LANCET. It began with a 'model ascent of Mont Blanc,' significantly enough achieved by a medical party of three—a student and two graduates in medicine, all of them Swiss. They started on Sunday morning, June 13th, at 6 o'clock, from Chamounix; reached the summit on Monday morning, and were back again in Chamounix the same evening. They had no guides and were favoured with weather so exceptionally fine that they passed under the 'séracs du Petit-Plateau,' a feat never attempted by climbers familiar with the risks of Mont Blanc. But then by profession they had the knowledge of the strength and staying power they possessed—'*quid valeant humeri, quid ferre recusent*'; they essayed the ascent, in short, with that best of all equipments—the assured boldness that springs from the ascertained adjustment of means to ends. Very different was the preparation with which two English ladies, as I have just heard, attempted from Zinal (Canton Valais) the ascent of the Garde de Bordon, 10,880 ft. above the sea-level. They had started for the Corne de Sorrebois, reached its summit without difficulty, and were tempted to essay the higher and sterner altitude. This, too, they achieved; but, being without guides, they lost their way in returning, and night surprised them wandering aimlessly among the rocks. At their hotel, meanwhile, solicitude as to their non-appearance deepened into anxiety, and anxiety into alarm, and at 9 P.M. two parties of guides started in search of them by different routes, while as the night wore on the front of the hotel was thronged with sympathising friends on the outlook for some signal intimating that one or other party had come up with the wanderers. At midnight the first party returned, *re infectâ*; the second appeared at 3 A.M. announcing that they had heard appealing cries from the heights, but unable to find the spot whence they proceeded they had abandoned the search, only, however, when the cries ceased. After a brief rest, however, a fresh start was made by the same party under the leadership of Baptiste Epiney, and at 9 A.M. far-off sounds were heard, and rightly interpreted as announcing that the wanderers had been found. By 10 A.M. all doubt was at an end, as the whole party, the two ladies, the five guides, and their leader, re-entered the hotel amid the cheers of the guests. Never venture on the unexplored without a skilled guide is the moral driven home by this adventure, which might easily have become a tragedy. But will the moral be taken to heart? The Alpine experience of the next few weeks must vouchsafe the reply."

[1] THE LANCET, July 24th, 1897, p. 210.

THE INCREASE OF DIPHTHERIA IN LONDON.

IT is a most lamentable fact that with all our outlay on sanitation in London—and it is becoming a formidable element in our expenditure—the disease of diphtheria steadily goes on increasing in prevalence. We know this from the reports of individual parishes. But we have the same information from Mr. T. Duncombe Mann, the clerk to the Metropolitan Asylums Board, in an official statement made to the Board on Aug. 7th. "The disease," he said, "had been steadily gaining ground in London for a considerable time past, and its continuous development had puzzled their medical staff and everybody else who had examined into the matter." The same increase is observed in the provincial towns, but not to the same extent. Thus in them the death-rate from diphtheria rose in ten years from 0·27 to 0·38, while in the same period in London it has

Digitized by Google

increased from 0·41 to 0·6 per 1000. This increase obtains even in parts of London otherwise creditable in their sanitary conditions. Thus, the healthy parish of Islington, which has been commended to the public lately by its medical officer of health as a health resort on the score of a mortality lower than that of Hastings—12·6 per 1000, as against 13·0, in one sub-district indeed only 9·0 per 1000—and which formerly enjoyed almost perfect immunity from diphtheria, has to report a mortality of 0·71 per 1000 inhabitants. The fact is one for serious investigation by the local metropolitan authorities acting in concert with one another. At present it is discreditable to sanitary science to be able to give so poor an account of so grave a danger. The disease is five times more fatal at present than scarlet fever, according to the experience of the Metropolitan Asylums Board's hospitals, in which the mortality has been greatly reduced by the antitoxin treatment. It is not improbable that a little more attention to the circumstances of individual cases and the hygiene of the home and the school with which they are associated, together with more perfect arrangements for the early diagnosis and treatment of cases, would bring this grave disease under much more control than at present. Is it quite certain that we are on the right track in relying so entirely on isolation hospitals? It is true that when admitted the patients are well looked after. But everything, both for curing the patient and preventing the spread to others, depends on early diagnosis of the disease. This fact points strongly to the conclusion that every parish should make special arrangements for the early detection and diagnosis of cases at home and for looking closely after the other children of families in which one case has already occurred. Every sanitary authority should have a laboratory and provisions for a prompt report as to the existence of the diphtheria bacillus. This information can be procured in ten or twelve hours in the hospitals of the Asylums Board, and there is no reason why it should not be procured outside with equal promptitude. If cholera were prevalent we should see the parishes making all sorts of extra arrangements for its detection and control. The same principle should be applied in the case of diphtheria. Whatever the excellence of the system of isolation hospitals diphtheria is a disease in which much time is lost by relying on them, and it is by no means clear that parishes have not been made careless in respect to their duties by this system, which seems to relieve them of their individual responsibilities. The subject requires independent and close investigation.

THE SPAS OF MID-WALES.

THE group of spas comprising Llandrindod, Llanwrtyd, Builth Wells, and Llangammarch, is becoming rapidly more widely appreciated in England, especially in the neighbouring counties and in the great towns of Birmingham, Manchester, and Liverpool. We believe, however, that in London this district is still insufficiently known, both amongst medical men and the public, and therefore Dr. A. Foxwell's pamphlet on "The Spas of Mid-Wales"[1] comes opportunely. The mineral waters of this district may be classified into five groups: (1) The common salt waters at Builth Wells and Llandrindod; (2) the muriated sulphur springs of Llandrindod, containing both common salt and sulphuretted hydrogen; (3) the "pure" sulphur springs, chief amongst which comes the sulphur well in Dolecoed Park at Llanwrtyd; (4) the chalybeate springs at Llandrindod and Llanwrtyd; and (5) the so-called "barium water" of Llangammarch, which, with about 2 6 parts of common salt, contains about 1 2 parts of calcium chloride and 0·096 parts of barium chloride in the 1000. The Llangammarch water, therefore, contains slightly more of the barium salt than the "chloride of iron well" at Harrogate, and is without the iron of the latter. A notable difference between the chalybeate and muriated springs of Wales and many of the most noted springs of the Continent is the effervescence of the latter in consequence of free carbonic acid gas. The Llangammarch water is, however, artificially aerated for use as a table water in certain cases. On page 9 of his interesting pamphlet Dr. Foxwell mentions that the medical man at Llangammarch has already prescribed baths of the water and thinks that they had much the same action as those of Nauheim. Here we feel uncertain whether baths of the ordinary barium water are alluded to, in which case the results are astonishing, or whether artificial Nauheim baths are meant, made by the Sandow or some other method. Probably the baths referred to are the artificial Nauheim baths, for an account of their use at Llangammarch was given in THE LANCET of Jan. 4th, 1896, and during a visit to the spa last year we were shown the arrangements for Sandow's method of administering artificial Nauheim baths. All the spas of Central Wales afford good accommodation to visitors, but it is likely that at Llandrindod at least this will have to be considerably increased, for, although the different places are all useful, it cannot be denied that to the average townsman in search of a health resort the more invigorating air of the upper part of Llandrindod offers special attractions. In this respect the Lake Hotel at Llangammarch ranks perhaps next. Those wishing to take the Builth waters at the springs themselves would often have, if there were many of them, to put up at the town; in the beautiful neighbourhood of the Park Wells the accommodation is still very limited.

THE COLLAPSE OF THE POONA ALLEGATIONS.

THE Parliamentary session is, to the great relief of our legislators, over, but it should not be allowed to pass away without leaving some impression behind it of Lord George Hamilton's excellent and statesmanlike speech on introducing the Indian Budget and the debate which followed. India has recently passed through an almost unprecedented series of trials, and a severe strain has been imposed upon the Indian Government. That the Government had to encounter a serious socio-political risk and danger in dealing with plague in India will not be denied by those who know the religious feelings and caste prejudices of the natives of that country. While we had the hearty coöperation of all sections of the Indian community in dealing with famine, and our efforts were gratefully appreciated by the native population, the case was far different as regards the measures that had to be adopted for the suppression of plague. As the Secretary for India forcibly urged, the only effectual methods of dealing with this scourge are unfortunately repugnant to the instincts, customs, and usages of the natives and interfere with the privacy of their home life. To have let the epidemic run its course rather than face the unpopularity of attempting to stamp it out would not only have led to an enormous amount of suffering and great loss of life, but would probably have involved the economic and industrial ruin of India, boycotted as it would have been by the rest of the world—to say nothing of the cowardice and disregard of plain duty of such a course. A systematic method of house-to-house visitation and segregation of the sick had to be adopted, and but for the action of a clique in Poona who have always been hostile to British rule, making it an occasion of stirring up discontent by the spread of wilful and malicious falsehoods, the Poona murders would probably never have occurred. It is now admitted on all sides that the British soldiers acted with great heroism and with extreme kindness and consideration to the natives in performing their difficult task. We sympathise with

Digitized by Google

the indignation expressed by Sir M. Bhownaggree, and believe with him that the large mass of the native population in India is well affected to our rule and grateful for what has been done to relieve suffering in time of famine. They are, as a rule, a singularly patient, law-abiding, but ignorant and credulous people, and it is the plain duty of the Government to protect them against malicious attacks on their allegiance to it. The difficulties with which the Indian authorities had to contend in the repression of the plague were extreme, and the way in which they surmounted them is deserving of the highest praise. Sir H. Fowler made an admirable and strong speech in favour of the views expressed by the Secretary of State for India, and did not at all coincide with those who seem never to be so happy as when they are belittling the honest efforts of their countrymen abroad to do their best for the welfare of those they have to rule.

OVERCROWDING OF PLEASURE STEAMERS.

THE captains of several pleasure steamers have lately been fined for carrying an excess of passengers. In one case the number in excess was 461, and for this the fine amounted to £91 15*s*. It may be very tempting to carry as many as possible, and in holiday times there may even be some difficulty in regulating the amount; but those in charge must be given clearly to understand that the public must not be exposed to these additional dangers, and no doubt a heavy fine will bring the matter home to them better than any other method. Overcrowding in all public conveyances is a dangerous thing, and possibly one day we may look for some rules to this effect with regard to trains, which, not only at holiday times, but on ordinary days, are often very much fuller than they ought to be, and each carriage contains a great many more than it is ever intended to hold. Beyond the discomfort of passengers, however, there is, of course, not nearly the danger with regard to trains as with pleasure steamers, where a sudden panic may have the most disastrous consequences.

THE UNIVERSITY OF GLASGOW AND THE DISCIPLINARY POWERS OF THE UNIVERSITIES OF SCOTLAND.

OUR readers know that in the General Medical Council there is great desire to see the universities, and especially the Scottish universities, strengthened in their power of dealing in a way of discipline with offending or unworthy graduates. A most creditable step has been taken in this direction by the University Court of the University of Glasgow. Recognising the seemliness of the Scottish universities acting together and harmoniously in the matter they have adopted a memorandum on July 8th last urging the Scottish Universities Commissioners to leave on record in their final report such an expression of opinion as may tend to bring the Scottish universities into a line with each other or with those universities of the United Kingdom which either already possess or have expressed the desire to obtain further disciplinary powers in accordance with the expressed wish of the General Medical Council. The delicacy of this way of proceeding is very great and should overcome the apparent reluctance of the Edinburgh University to get powers which it needs as much as any other Scottish university. Of the university graduates who have been declared by the General Medical Council guilty of infamous conduct it is found that four held the degree of the University of Edinburgh; four that of the University of Glasgow; one that of the University of St. Andrews; and two that of the University of Aberdeen. It is inconceivable that the great University of Edinburgh should be really reluctant to purge its roll of dishonourable names. Anyhow, the University of Glasgow has made a most reasonable suggestion. If the Commissioners still hold to a Gallio-like attitude the University of Glasgow should make its own appeal to the Privy Council, seeking, if possible, the coöperation of the other Scottish Universities.

STREET RUFFIANISM.

STREET ruffianism is at present far more common than it ought to be, both in London and other large towns. In Liverpool Mr. Justice Bruce has lately passed sentence on no less than fifteen prisoners who had been convicted, and in sentencing them his lordship made some strong remarks upon the subject, stating that one would almost think Liverpool was a barbarous country instead of a civilised community, judging from the use of the knife by men and women. In London, too, we hear of different gangs which infest certain neighbourhoods at night—such, for instance, as the Bethnal-green gang and the Hoxton gang, which have apparently waged war against each other for a long time, much to the danger and annoyance of the more peaceful inhabitants. Weapons of all kinds are frequently used, and it will be remembered that it was in one of these fights that a little girl was recently shot dead. It is a pity these bellicose youths cannot find some more useful outlet for their animal spirits; but if any special romance surrounds these little meetings perhaps a period of hard labour will to some extent make things appear different. We are glad to see that this class of case is being severely dealt with, for it is monstrous that people should not be able to walk about the streets after dark without being liable to annoyances and risks of this description.

MICROSCOPICAL EXAMINATION OF MILK.

IN the *Medical News* (New York) of July 10th of this year is an interesting article on the Microscopical Examination of Milk, by Dr. W. R. Stokes, bacteriologist to the Health Department of Baltimore, and Dr. A. Wegefurth, physician to the North-Eastern Dispensary, Baltimore. They draw attention to the fact that milk is a favourable medium for the dissemination of tuberculosis and also for the development of many other pathogenic bacteria, such as the bacillus of typhoid fever and of anthrax. The paper under consideration, however, deals mainly with another condition—i.e., the means of detecting a serious contamination in milk, namely, pus. The presence of this product of inflammation in any considerable quantity generally points to the existence of some inflammatory condition of the teats or udder of the cow supplying this fluid. Such a condition in cattle is known as "garget." After describing the methods employed in examining milk for pus and giving a detailed account of an epidemic of mild gastro-intestinal irritation in which the most reasonable explanation of the cause seemed to be the drinking of milk containing the products of acute inflammation from a diseased cow, the writers arrive at the following conclusions. Garget, or inflammation of the udder, is a not infrequent condition among the many herds supplying milk to various cities or communities. Milk from such animals often contains many pus cells and the accompanying organisms of suppuration. A study of the epidemic described in the paper as well as of the important work of Booker and others certainly strongly suggests that such milk is capable of causing the various forms of gastro-enteritis, especially in children and infants. The microscopical examination of the centrifugalised sediment of the milk from a herd of cattle, if found to contain an excessive amount of pus, should lead to a careful inspection of the herd. The chance of infection from drinking milk from a large herd can be lessened by making a microscopical examination of the centrifugalised specimen from each cow and by the exclusion of such cows from the

Digitized by Google

herd as may be found to give milk containing an excessive amount of pus. The standard for exclusion must of necessity be arbitrary; but, following the method described in their paper, the writers suggest that an average of more than five pus cells to the field of a twelfth-inch oil immersion lens should exclude an animal from the herd. In Baltimore, a city of 500,000 inhabitants, there were 412 deaths from cholera infantum during the year 1896. This disease is more prevalent among children using cow's milk, and Dr. Stokes and Dr. Wegefurth believe that proper legislation looking to the examination of dairy herds and the supervision of dairy stables would prevent many deaths from the various intestinal inflammatory diseases. It is not claimed that milk which has not undergone such tests will necessarily cause disease, but certainly the adoption of such measures will tend towards securing a purer milk supply and lessening the danger of disease through infected milk.

THE UNHEALTHINESS OF BOMBAY.

THE unhealthiness of Bombay continues, and is much commented upon in the Anglo-Indian papers. The official returns regarding the plague are satisfactory, but doubts are expressed as to whether the city is altogether so free from that disease as these returns indicate, and whether some of the prevailing cases of fever attended with pulmonary complications be not really a form of that disease. Anyway, the state of the public health in Bombay is unsatisfactory, the weekly death-rate from all causes having been over 65 per 1000. Cholera has been prevalent and has added much to the mortality. The drainage of Bombay is bad and the soil of certain districts is water-logged and probably more or less contaminated with sewage. The Health Department have adopted vigorous measures and are endeavouring to stamp out the disease. Cholera has also prevailed at Sholapa, Poona, and at a village named Walwan.

"CARDING" THE SCIATIC NERVE.

THE operation of "carding" or "harrowing" the sciatic nerve for very obstinate sciatica was first performed about a year ago by Dr. Delagénière of Mans in a case in which he presumed that the cause of the pain was a varicose condition of the veins surrounding the nerve. The intention was to excise these veins after the method recommended by Quénu, but when the nerve was exposed instead of the varix he expected he found only a number of small serpiginous vessels running along it, causing the surface to present a furrowed appearance. It was obviously impossible to ligature and resect these, so he contented himself with easing or carding the fibres with a blunt forceps throughout the whole exposed portion of the nerve in the hope of destroying the vessels existing in its deeper parts and of thus being able to put an end to the stasis in the venous twigs. The result was that the patient was cured. This encouraged another French surgeon, Dr. Gérard-Marchand, to attempt a similar process which he denominates *hersage* or "harrowing" in sciatica where there was no reason to suppose that a varicose condition existed. The first case was that of a woman, aged thirty-seven years, who was unable to sleep or to stand upright, characteristic scoliosis being present. There were no signs of varicose veins or of hysteria. The second was that of a man, aged forty-five years, with a very old-standing sciatica, no treatment having been of any avail. Here also there were no varicose veins. The operation, which was similar in the two cases, was performed under chloroform, and consisted in exposing the nerve and teasing apart its fibres for a distance of two centimetres by means of a grooved director. The appearances were normal, there being no discolouration and no dilatation of the vessels. After the *hersage* the nerve was flattened out to twice its ordinary breadth. A drainage-tube was inserted and the wound sutured and dressed with iodoform and absorbent cotton wool. For several days the patients complained of pain in the nerve and of numbness in the limb. The pain, however, gradually passed off and sensation returned, complete recovery resulting in both cases. From experiments on animals Dr. Gérard-Marchand has been led to conclude that *hersage* of the sciatic nerve produces temporary loss of sensation in the nerve, while the motor power is not interfered with. He suggests that probably this operation may be found of value in the case of other neuralgias which have resisted all ordinary treatment.

OFFAL COLLECTING AND SAUSAGE-MAKING.

A MAN whose business it is to collect offal for the purpose of making manure should be careful, it might be thought, not to combine that of sausage-making, as the public, did they know, might attach an unpleasant connexion between the two callings. The vestry of St. George the Martyr entertained a suspicion of this sort last week in regard to a butcher, and on inspecting his premises found all the evidences of sausages being in process of manufacture, and in addition pieces of bad meat and mouldy bread. The defendant said that the meat on the counter was waiting to be taken away in the offal van, but he omitted to say anything about the mouldy bread, although he ventured the opinion that thunder had turned the brine sour, and the meat taken out of such a profoundly modified pickle possessed on that account "a nasty smell." We rejoice that Mr. Slade, the magistrate, concluded that, although it might be true that the 113 small pieces of meat in the cellar were only to be used as manure, it must not be forgotten that there were larger pieces of meat in the basement. He ordered the defendant to be fined £20 and 2*s*. costs in each case, and, we hope, the latter will take to heart the teaching of science that manure is an excellent and wholesome food for the plant, but it may mean illness and perhaps death when consumed as human food. It is a pity, we think, in cases of this sort that the person committing the offence is not consigned to imprisonment and compelled to subsist—if that be possible—on the rotten mixture which he prepares for public consumption.

PEMPHIGUS OF THE MOUTH.

THE eruption of pemphigus sometimes occurs in the mouth and on other mucous membranes. That the disease in the mouth may precede that of the skin in the ordinary form of pemphigus—the chronic—is not generally known, though this is what invariably occurs in a rare form, pemphigus vegetans, and that the disease may remain localised to the mouth and adjacent cavities for a long time, and in some cases entirely, does not appear to be at all recognised in this country. In the *New York Medical Journal* of July 3rd Dr. Lewis H. Miller describes a case in which the mouth was affected for twenty months without the skin being involved. The patient was a man, aged seventy-two years, who complained of soreness in his mouth and inability to take solid food. On the roof of the mouth and on the epiglottis were patches of false membrane of considerable thickness, which when removed left a raw, bleeding surface. Some decayed teeth were extracted and antiseptics used, but blebs formed on the roof of the mouth, the soft palate, the cheeks, under the tongue, and on the posterior wall of the pharynx. Bacteriological examination of the membranes gave negative results. There was neither fœtor nor salivation. Whenever the patient attempted to masticate solid food a fresh crop of blebs appeared. We consider this fact of great interest and importance. It is perfectly analogous to what may occur in pemphigus of the

Digitized by Google

skin; for local injuries, and even friction or pinching, will in some cases determine the formation of a bulla at the spot. No stronger confirmation of the diagnosis of pemphigus of the mouth when the eruption on the skin is absent could be given than this production of bullæ by such trivial exciting causes. Nothing of the kind, as far as we know, occurs in any other disease. Dr. Miller quotes a number of cases in which the disease existed for long periods, in one as much as eleven years, in the mouth before the skin was affected. The rare disease pemphigus of the conjunctiva may be very instructively compared with pemphigus of the mouth, because in the former disease also a skin eruption may be either absent or present. The treatment is similar to that of pemphigus of the skin, though it does not appear to be very successful. In the case given arsenic seemed to produce some improvement. Opium might be tried. Mr. Hutchinson has shown it to be distinctly curative in some cases of pemphigus in which the mouth is primarily involved.

THE EAST LONDON WATER-SUPPLY.

COMPLAINTS have once more been heard as to a deficiency in the supply of water in certain parts of the East-end of the metropolis. Inquiry at the offices of the East London Waterworks Company appears to have elicited two facts—viz., (1) that a breakdown occurred in the Thames supply main, and (2) that in many instances the water did not flow into cisterns fixed at a point higher than forty feet from the ground. Whether the latter occurrence was due to the former we do not know, but we cannot understand why there should be any serious deficiency in the supply, for as yet we have experienced no prolonged drought, while since the memorable drought in the summers of 1895 and 1896 the company have added enormously to their storage capacity, so that it is now equal to 1,000,000,000 gallons, and the average supply to about 320,000,000 gallons per week. The company do not guarantee a supply of water at a higher point than 40 ft. from the ground, but as, obviously, there are hundreds of poor tenements situated at this height and above it is perfectly absurd that the company should be allowed to shield themselves behind this announcement.

HEREDITARY AND CONTINUOUS SHEDDING OF THE FINGER-NAILS.

IN the June number of the *Journal of Cutaneous and Genito-urinary Diseases* Dr. Douglas W. Montgomery describes the following very curious case. A man, a native of Les Basses Pyrénées, in excellent health, had been troubled ever since birth with constant shedding of the finger-nails. His mother and two of her brothers were similarly affected. One or two of the patient's nails were always falling. The process commenced by the colour growing dull yellowish-white directly over the lunula or on one side of it. The nail then became lifted from its bed from behind forwards until it fell off. The shedding occupied about three months. The new nails grew in from three to eight months and were perfectly normal. There was no pain or inconvenience. The hair grew vigorously and showed nothing abnormal. The teeth were excellent. There was no disease present which is associated with shedding of nails.

UNIVERSITY COLLEGE, LIVERPOOL.

THE report of the Medical Faculty of University College, Liverpool, for the session 1896–97 is highly satisfactory. The numbers of students are again this session the largest on record, and are considerably in excess of last year's increase. The increase is accounted for by a remarkable addition to the numbers of those preparing for diploma examinations. The obvious reasons why these latter examinations are taken in lieu of the university curriculum is the want of adequate secondary education and proper relation between school education and the university entrance examinations. It is hoped that this defect will be remedied in course of time. 139 students have passed professional examinations as against 130 last year (119 being medical and 20 dental). Of the medical students, 78 have passed university examinations, 72 at the Victoria University and 6 at other universities; 41 have passed various examinations of the English or Scottish Corporations. Twelve candidates from University College, Liverpool, presented themselves at the recent final examination of the Victoria University for the degree of Bachelor of Medicine and Surgery, 9 of whom were successful. Of these, 5 obtained second-class honours, representing upwards of 55 per cent. of the honours awarded. The results of this latter examination are highly creditable to the Liverpool School, and accentuate the successes of last year, when, at one of the final examinations, all the honours were carried off by candidates from University College, Liverpool.

THE JOHN LUCAS WALKER STUDENTSHIP.

THE John Lucas Walker Studentship is intended for the furtherance of original research in pathology, and is tenable for three years. It is of the annual value of £250; it is not awarded by the result of a competitive examination, and it may be held by a person of either sex, who shall not necessarily be a member of the University of Cambridge. The holder of the studentship shall undertake original pathological research, and shall not systematically follow any business or profession, or engage in any educational or other work which, in the opinion of those entrusted with the administration of the fund, would interfere with the carrying on of original inquiries. If during the tenure of the studentship the holder is appointed a professor or accepts a Fellowship other than an honorary Fellowship, he shall thereupon vacate the studentship. Candidates are requested to apply not later than Oct. 15th to Dr. A. A. Kanthack, Pathological Laboratory, Cambridge. The place and nature of the studies of the student shall be subject to the approval of the Professor of Pathology; he or she will, however, be required to work at the University during at least three terms of the tenure of the studentship.

THE HEART IN NERVOUS DISEASES.

AVAILING themselves of the opportunities afforded in the out-patient department of La Pitié Hospital, Mdlle. Pokrychkine and M. Capitan have conjointly carried out an extended series of investigations with a view to determining what alterations of shape and volume occur after muscular exertion in the hearts of persons who are suffering from nervous affections. While prosecuting their researches, of which a *résumé* has been communicated to the Société de Biologie, the observers made use of a modified form of Bianchi's phonendoscope; and they also executed careful tracings showing the contour of the cardiac region before and after exercise. The results arrived at by Mdlle. Pokrychkine and M. Capitan may be briefly stated as follows: 1. In normal subjects moderate exercise does not cause any perceptible changes in the heart with regard to shape, volume, or position. 2. In subjects whose nervous systems have undergone deterioration in consequence of hysteria, neurasthenia, or any reflex trouble having its point of departure in a particular part of the organism, the heart grows hyper-excitable, and changes in shape or position the moment it is called upon to do a little extra work. This alteration may present itself in three typical ways. (*a*) The whole cardiac area may be uniformly enlarged, or the increase may be partial and irregular. (*b*) The heart may become retracted and diminished in volume. (*c*) Finally,

Digitized by Google

the organ may be dislocated laterally, with or without changes of shape and volume, the displacement being directed towards the mesial line or more frequently towards the axilla.

THE FOUL STATE OF THE BRENT.

THE Brent no longer flows, it stagnates, and since sewage is discharged into it the river (so called) has very naturally become a source of abomination to those who are unfortunate enough to be, or live, in its neighbourhood. And this shocking state of things has come about because more than a hundred years ago a canal company obtained powers to impound practically all the water flowing, in consequence of which in summer very little water comes down at all. What we should like to know exactly is who is responsible for the direct befoulment of the river, as surely it is insisted that no untreated, or imperfectly treated, sewage is discharged into the water. The sooner the flow of the river is restored the better, and whatever else is done steps should be instantly taken to avert the untold mischief of converting the bed into a huge cesspool by the discharge into it of more or less crude sewage. Let the Middlesex County Council bestir themselves in this matter if they would avoid an epidemic, and show the same commendable spirit of activity as they have shown in other matters connected with public health. Since the above was written we learn from the *Times* of the 12th inst. that, as the result of the inquiry in the House of Commons last week, the Local Government Board instructed the chairman of the Middlesex County Council to take immediate steps to have the River Brent cleaned.

HOME-GROWN FOOD IN RELATION TO HEALTH.

CLIMATIC conditions, as is well known, have a good deal to do with the suitability of food. The Esquimaux has an innate craving for fat, which is supplied him in the oleaginous blubber, while the Indian or African or nigger would naturally have an aversion to rich fatty food, and so he eats starchy food and fruits which grow in abundance around him. The same principle is illustrated even in the comparatively narrow range of climatic conditions in this country. Who has the same inclination to eat a large, underdone, juicy steak in the broiling days of our short summer as in winter? We rather have recourse to salads, fruits, vegetables, and if to meat at all it is in sparing quantity and generally cold. But as an agricultural correspondent has most ably and pertinently pointed out to us in a recent very interesting communication, the subject may be pushed a step further, and considered from a point of view which in its general bearings on the question of food supply is of unquestionable importance. As he has observed, the same plant varies in its feeding properties when grown at a different altitude, or on a particular soil, or in a different climate. In other words, the nutritive value of a plant or its fruit, be it seed, fruit, or leaf, is influenced by soil and climate. Herbage composed of grasses and clovers—i.e., pasture—has a marked influence upon the health, development, and early maturity of sheep and cattle according to geographical position and geological character of the soil. Thus "storeland" and "feeding land" are terms used to express the relative character of the soil, and, as our correspondent (who is a farmer) points out, these varying conditions have a well-known influence altering or modifying the type and character of breed or pedigree. Is it a design in Nature, he asks, that plants growing in any particular country shall be more suitable food for animals in that particular country than foreign food or that grown in a different country? As an illustration, linseed or flax seed produced in one country is full of oil, and in another the proportion of oil is distinctly less; a sample of seed in one country again is rich in mucus, while in another it contains very little mucilage, the difference in this respect in Russian, Indian, and English seeds being considerable. Again, he asks, does Assam tea afford a more healthful beverage to the Chinaman than Indian tea? yet the character of the two decoctions made from these respective teas is quite different. To come nearer home, and to touch upon the economic side of the question as closely affecting our own agricultural interests, Is English wheat made into bread a better food for the people in this country than bread made from foreign flour? The baker selects foreign flour because the resulting loaf is lighter, and the flour will take up more water, and a sack will yield a greater number of loaves than an English sack. There could hardly be opened up for discussion a more interesting phase of the subject, and our correspondent has written very pertinently upon a very important question. It is just possible on studying and reflecting upon the issues he has raised that another rational and powerful argument in favour of the consumption of home-grown food may be found.

THE PARISH OF ST. JAMES'S, WESTMINSTER.

IN not a few instances the fine streets of which part of older London is made up convey to the visitor to the metropolis—and, for that matter, to the majority of Londoners as well—a very fictitious idea of the class of houses and people inhabiting certain areas. Behind what must be regarded as a veneer of the fine houses on either side of some of the big thoroughfares there lies a mass of obsolete and closely packed slum property, ill-provided with light and ventilation. Many of these slums have within recent years been opened up to the purifying effects of destruction and light by the handsome avenues which have been constructed through their midst, but there still remains much to be done—more, perhaps, than most people have any idea of. The parish of St. James's, Westminster, contains within its area some of the finest streets and buildings within the metropolis, but most people who have regard to the distribution of the parish on the map of London will be surprised to hear that it still contains some very bad slums. It is, however, perfectly true, as Dr. James Edmunds, the medical officer of health of the district, tells us in his current annual report, that if a line be drawn diagonally across the parish from St. James's Palace to the junction of Wardour-street with Oxford-street, that portion of the line south of Regent-quadrant will traverse a neighbourhood remarkable for its wealth, while that north of the quadrant will lead through a neighbourhood not a little of which is remarkable for its poverty and dirt. This northern area of the parish is to a large extent covered, Dr. Edmunds states, by old houses which are in the hands of "tenement-mongers," and which are let out as lodgings to the dependents of the shops and warehouses in Regent-street, Bond-street, Piccadilly, and St. James's-street. The rents are high, but the accommodation is bad, and the short leases of the tenement-mongers practically debar the freeholders from rebuilding or making substantial improvements. The worst houses and the dirtiest of the inhabitants have been in large part forced out by the need for wholesale warehouses and workshops in this locality, and Dr. Edmunds thinks that the time has now arrived when the process of displacement might be profitably hastened by opening up a new street on the eastern side of, and parallel to, Regent-street. He suggests that such new street might be in direction an extension of Waterloo-place or of the Haymarket, Suffolk-street or Whitcomb-street, and he thinks that a new street running through to Poland-street would have the additional advantage of enhancing the value of the site upon which the Westminster Workhouse stands, while it would be of great use to the metropolis. The poor of the Westminster Union are, Dr. Edmunds tells

Digitized by Google

us, "consigned to a deplorable existence," and he asks whether a small receiving house in St. James's and a comfortable workhouse in the country would not be both a blessing to the poor and a great saving to the ratepayers. As to the question of economy we cannot speak, but we can fully confirm Dr. Edmunds's statement as to the conditions of much of the property in the area in question. We have recently visited parts of it, and we were astonished at the sudden transformation scene which took place as we passed from Coventry-street to the district referred to. The opening up of the worst parts of this area is much to be desired, and Dr. Edmunds's proposal is well worthy of being further elaborated.

SIR ARTHUR SULLIVAN has forwarded to the Prince of Wales a cheque for £202 for his Hospital Fund for London, representing the sum paid by Messrs. Eyre and Spottiswoode in respect of royalty on the sales of the late Bishop of Wakefield's Jubilee hymn, of which the copyright had been assigned to him by the author. The donation was accompanied by the expression of a wish from Sir A. Sullivan that it should be considered as a joint gift from the late Bishop of Wakefield and himself, being their share of the proceeds.

THE Queen has been graciously pleased to sanction the following appointments to the Order of the Hospital of St. John of Jerusalem in England:—Knights of Grace: Charles Knott, M.R.C.S. Eng., and Charles Joseph Trimble, L.R.C.P. Edin., from Honorary Associates.

UPON Aug. 11th a bronze statue of Darwin was unveiled in front of the Shrewsbury Free Library, which was formerly the old Shrewsbury school where Darwin was educated.

PROFESSOR MCWEENEY, M.D. R.U.I., has been appointed representative of the Royal University of Ireland at the International Medical Congress to be held at Moscow next week.

Pharmacology and Therapeutics.

CREOSOTE IN GASTRIC AFFECTIONS.

ACCORDING to Dr. Theodore Zanger, of Zürich, who has contributed a paper on creosote to the *Correspondenzblatt für Schweizerische Aerzte*,[1] the present tendency to think that the larger the dose of this drug the better in phthisical cases is by no means justified by experience, for the best results are often obtained with very small doses indeed. He believes that their beneficial effect is due to their action on the stomach, causing it to do its work better and so to improve the nourishment of the system. He finds that in many cases of purely gastric affections, with or without diarrhœa or other intestinal symptoms, minute doses of creosote will often succeed when other remedies have failed. In the gastro-enteritis of children and in the vomiting of pregnancy he has been greatly struck with its effects. The doses he gives vary from one-eleventh of a grain in children to one-third of a grain in adults. He prescribes it with enough spirit to dissolve it in a spoonful of water, with or without mucilage. Black coffee or mint tea may be employed, if necessary, to disguise the taste. Where infantile diarrhœa exists without vomiting he has often found creosote valuable. In the milder forms of the vomiting of pregnancy small doses of creosote have always produced an improvement, and he thinks that even in severe cases a trial of the same treatment should be made.

OXYCAMPHOR IN DYSPNŒA.

Oxycamphor, which, from physiological and clinical observations that have been already made upon its action, bids fair to be reckoned among the more useful of the ever increasing number of artificially prepared drugs, is, chemically speaking, camphor in which a molecule of hydrogen is replaced by one of hydroxyl; it is prepared by reducing camphor-orthochinon by means of powdered zinc and acid. It is a white, crystalline powder with a melting point of about 204° C. It is soluble in cold water to the extent of 2 per cent., but more so in hot water, and readily in all organic menstrua with the exception of ligrosin, the solution in water having a slightly hot and bitter taste. Solutions of albumin are not affected, but myosin is precipitated in flocculi. Oxycamphor is inimical to low forms of organic life, bacterial growth, putrescence, and fermentation being markedly retarded by a 0·1 per cent. solution and entirely stopped by a 0·5 per cent. solution. When added directly to blood oxycamphor causes the hæmoglobin to become converted into methæmoglobin and otherwise appears to hinder the absorption of oxygen. When injected into the lymph sac of a frog oxycamphor behaves like camphor in paralysing the muscular coat by acting on the motor nerve endings; the action of the two drugs on the heart, however, is dissimilar, inasmuch as camphor excites the movements when they have been arrested by muscarin, not only when applied by intravenous injection, but also when a dilute solution is sprinkled on the organ, so that it cannot cause coagulation of the myosin; oxycamphor, on the other hand, however applied, causes retardation, or even actual arrest, of the frog's heart. In warm-blooded animals the difference in the action of the two drugs is even more remarkable, camphor producing in large doses mental excitement and rapid respiration from its irritant action on the fourth ventricle; whereas when 0·25 gramme is given to a dog subcutaneously or a gramme by the mouth the breathing becomes quieter, more regular, shallower, and very much slower. When 0·025 gramme is introduced into a vein the slowing of the respiration is very soon followed by its entire cessation, showing that the drug acts upon the respiratory centre. The vaso-motor centre is not affected, except secondarily through the respiration. Numerous experiments have shown that even long-continued and considerable doses do not set up any by-effects in other organs, so that oxycamphor would seem likely to prove a valuable therapeutic agent in dyspnœa due to circulatory disturbance. Ewald and Kuttner have made some trials with it and have obtained results which are decidedly encouraging. They consider the dose to be from 7 grains to 15, and the quantity per diem from 30 to 45 grains.

DERMATOL AND ITS INTERNAL ADMINISTRATION.

Dermatol is, as is now well known, a basic oxide of bismuth and has been employed with considerable success as a substitute for iodoform in the treatment of wounds, having both the desiccating power of bismuth and the hæmostatic and astringent characteristics of gallic acid. Its employment as a drug for internal administration up to the present has not been at all general, though Colasanti and Dutto have prescribed it with advantage in various cases of intestinal catarrh and Werther has found it useful in chronic intestinal catarrh. Dr. Perlmutter has recently published a paper in the *Münchener Medicinische Wochenschrift* on its employment in gastric ulcer and diarrhœa, his observations being made on an extended series of cases and being inspired by Professor Moritz who recommended it to his notice. In diarrhœa in phthisical subjects and in acute and chronic enteritis he found it most valuable, all cases of this kind benefiting by its use, and the result being by no means only of a transient character. The drug was given in doses of from 8 to 30 grains in water twice a day. It is not poisonous, and produces no by-effects except a tendency to constipation, which can be readily combated by means of glycerine enemata. In gastric ulcer, too, it was very useful, especially in acute cases where patients could be kept at rest and properly dieted and made to lie on the affected side after taking the dermatol so that it might come into contact with the lesion itself. The doses given were 8 grains at the beginning, gradually increasing to 30 grains twice a day. Of course, when bismuth is being given, the stools will be dark, and care must be taken not to mistake them for those coloured by blood.

HYPODERMIC INJECTIONS IN EXTENSIVE BURNS.

Professor Tommasoli, of Palermo, recommends large hypodermic injections of artificial serum—i.e., water containing 0·6 of common salt—in case of extensive burns with the object of washing away the toxins which accumulate in consequence of the suppression of perspiration by the

[1] No. 12, 1897.

Digitized by Google

destruction of the sudorific glands. In one very severe case, where this treatment was only commenced after diarrhœa and delirium had set in—although the case proved fatal,—a distinct improvement was observed after each injection. In another where, though the burnt surface was even more extensive, the treatment was commenced almost immediately recovery took place. Here 250 grammes were injected at first, the quantity being increased daily until the fifth injection, when 500 grammes were given. This quantity was continued daily for nineteen days. Of course the wounds were dressed antiseptically.

THE EASTBOURNE WATER-SUPPLY.

HIS GRACE THE DUKE OF DEVONSHIRE, K.G., formally opened the new (Friston) waterworks at Mead's Hill on Aug. 6th. After the interesting ceremony, which consisted of the opening of a valve by his Grace, which caused a fountain to throw forth a stream of water, and the presentation of an address by the Town Clerk on behalf of the Corporation of Eastbourne, the party proceeded to the Queen's Hotel, where an excellent luncheon was rovided.

Eastbourne is one of the most pleasant of watering-places, and its health statistics compare favourably with other towns. The Registrar-General's annual report for 1896 on the health of the 100 large towns of England and Wales shows Eastbourne to have had the lowest death-rate of all the said towns with one single exception. The same report for the first quarter of the present year shows the town to have had at least 50 per cent. fewer deaths from "principal zymotic diseases" than any other of the south coast towns mentioned, there being only two of the whole 100 towns with fewer such deaths. For the same quarter it is shown to be the only town of the whole 100 whose total deaths for the quarter are under three figures, the total inclusive death-rate for that period being but 8·0 per 1000 per annum. Unfortunately, however, certain mineral salts obtained entrance to the water-supply, and a rumour gaining ground that the water was unhealthy the town had in consequence suffered. The corporation, recognising the importance of having a pure water-supply, determined to promote a Bill in Parliament to acquire the water company's rights and also to secure a new supply, but the preamble of the Bill was not proved. At the same time the water company were applying for fresh powers to enable them to obtain a new supply of water from Friston, which supply was formally opened on Aug. 6th. The following analysis by Sir Edward Frankland includes the supplies from Holywell and Wannock as well as from Friston.

Results of Analysis expressed in parts per 100,000 (April 5th, 1897).

Description of well.	Total solid matters.	Organic carbon.	Organic nitrogen.	Ammonia.	Nitrogen as nitrates and nitrites.	Total combined nitrogen.	Chlorine.	Hardness.		
								Temporary.	Permanent.	Total.
Holywell ...	32·24	0·055	0·010	0	0·664	0·674	5·2	14·5	7·3	22·8
Friston Well	37·08	0·041	0·012	0	0·656	0·668	4·3	16·9	7·0	23·9
Wannock Well	25·24	0·043	0·011	0	0·096	0·107	2·6	15 2	4 2	19 4

In considering Sir Edward Frankland's results we may remark that they compare very favourably with the analyses of water-supplies of well-known purity elsewhere. They show that high degree of organic purity characteristic of waters derived from a chalk bed, almost the whole of the nitrogen present being in the form of nitrates. Though somewhat hard, the new supply is not worse in this respect than some of the London water-supplies, notably that supplied by the Kent Company from the deep chalk wells, which contains 27·8 parts per 100,000, while the hardness of the New River supply is not less than 20 parts per 100,000. The proportion of combined chlorine is, however, slightly above the usual average, but this may be attributed to the near proximity of the sea. The old trouble, however, was due to the access of certain salts, and doubtless the corporation authorities will have the water examined from time to time so as to keep a close watch on any variation that may occur in this particular.

Immediately after the ceremony at Black Robin, where the water was formally turned on, the company and guests proceeded to the Queen's Hotel for luncheon, when Alderman Skinner, the mayor, presided, on his right being the Duke of Devonshire, the chairman of the Eastbourne Water Company, and on his left Admiral Field, Member of Parliament for the Borough. Among those present were Sir W. Charley, Surgeon-General Beatson, Aldermen W. H. Burt, W. Pocock, J. Rudd, N. Strange, and H. Sutton; Councillors C. L. Adams, C. Breach, B. Bradford, E. Duke, J. C. Foran, J. Harding, A. C. Hillman, C. O'Brien Harding, R. G. Job, R. C. Lambert, M. Martin, O. Mitchell, A. H. Maude, W. Pearce, T. B. Rowe, A. P. Sherwood, C. F. Simmons, W. Sharp, J. C. Towner, J. White, J. T. Wenham, J. C. Wright, and J. Welch; Mr. H. W. Fovargue, town clerk; Mr. R. M. Gloyne, borough engineer; Dr. W. G. Willoughby, medical officer of health; Mr. A. Allcock, borough accountant; Mr. H. Plumb, chief constable; Messrs. G. E. Quirk and J. H. Wright, borough auditors; Mr. C. Tomes, consulting surveyor; and Messrs. J. Aird, jun., C. Aird, H. Andrews, D. Allum, J. Adams, M.D., Alderman Bray (St. Leonards), Matthews Browne, M.D., H. Colgate, M.D., E. Downes, M.D., Kenneth Frazer, M.D., T. S. Gowlland, H. S. Gabbett, M.D., F. Hollins, H. Habgood, M.D., C. N. Hayman, M.B., J. Jacobs, G. A. Jeffery, M.D., Talfourd Jones, M.B., R. Morland, T. Macqueen, M.B., G. A. Skinner, and W. Muir Smith, M.B.

Following the toasts of "The Queen" and "The Prince and Princess of Wales," which were received with vocal and instrumental honours, came the toast of "The Eastbourne Water Company," proposed by the MAYOR. They had always, he said, at Eastbourne been proud of their abundant supply of pure and wholesome water, but unfortunately about three years ago some little difficulty arose in consequence of the drought and the very rapid growth of the population. This put a great strain on the source of the supply. Subsequently the water became saline, though it was at no time injurious to health. Complaints were made to the corporation, and they made representations to the company, who set to work to obviate the difficulty, which had now been overcome.

The Duke of DEVONSHIRE, in replying, said the prosperity and welfare of Eastbourne depended almost entirely upon the number of visitors it could attract. If the visitors were not satisfied with the air or the water they would stay away. Up to a very recent period among the many advantages which they were proud to think Eastbourne could offer to its visitors was its complete and perfect water-supply, but in the year 1893 or 1894, for the first time after a period of long-continued drought, the supply at Bedford well showed some indications of diminishing in quantity. In consequence of that diminution some new extensions to the works at Holywell were made, by which it was anticipated that the failing supply of water could be recruited. That anticipation was realised. The fresh headings which were constructed did produce an additional supply of water, but unfortunately at the same time a great increase in the amount of chlorine contained in that water became manifest. In consequence of that something approaching to a panic took place, but at no time had the supply of water for Eastbourne been of a character which was injurious in any degree to health. That statement could be verified authentically from the returns of the Registrar-General. Owing to their possession of unrivalled means and connexions with the firms which alone were capable of supplying the necessary engines and pipes, the work at Friston was entrusted to Messrs. Aird and Co., who, in the course of two months, had been enabled to put down the necessary pumping appliances at Friston—a distance of over four miles from Black Robin, separated from that place by two ranges of considerable eminence—to lay down the pipes and supply the reservoirs with 800,000 gallons per day of pure and abundant water. The wants of Eastbourne at the fullest period were estimated at something like 1,500,000 gallons per day. More than one-half of that quantity was now assured from Friston, but they were not dependent even upon Friston alone. In addition to the Friston supply there

Digitized by Google

were large supplies from Holywell, from Wannock, from Filching Glen, and from the Warren, which are amply sufficient for all the probable or even possible necessities of Eastbourne. Before concluding his Grace expressed the hope that the proceedings of the day and the extremely kind and cordial address which he had had the pleasure of receiving at the hands of the Corporation would put a final end to any differences which had existed between the water company and themselves. His Grace then proposed the health of the Mayor and Corporation.

In his reply the MAYOR invited the Duke to accept the civic chair on the occasion of the next election.

The toast of "The Visitors" was proposed by Admiral FIELD, C.B., M.P., and responded to by Mr. R. D. M. LITTLER, Q.C. Sir ELLIS ASHMEAD BARTLETT proposed the health of the Press.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A COUNCIL meeting of the Metropolitan Hospital Sunday Fund was held in the saloon of the Mansion House, London, on Aug. 5th, for the purpose of approving the report of the Distribution Committee for 1897. In the absence of the Lord Mayor Sir SYDNEY WATERLOW presided.

Proposing the first motion, "That the report of the Committee of Distribution for the year 1897 be and is hereby approved, and that the several awards recommended be paid as soon as possible," the Chairman reminded the meeting that this was the silver jubilee of the Fund. During the twenty-five years it had collected £918,432, and distributed £853,013; 35,802 surgical appliances had also been distributed. Referring to the amount collected this year he said that it was not quite so large as last year, when they paid away £41,829, but the deficiency of £2124 was not a serious one considering the difficulties under which the Hospital Sunday Fund had to be worked, and the extent to which the public had responded to other appeals in aid of the hospitals. The committee had decided to divide the money received almost to the last penny. They had never proposed, and he hoped they never would, to build up anything like a reserve fund. They had acted on the principle that the money placed in their hands by the generous public was intended for the relief of disease and sickness in the particular year in which it was given.

Sir EDMUND HAY CURRIE seconded the motion.

Sir DYCE DUCKWORTH wished to know whether St. Thomas's Hospital had applied for a grant, and, if so, why the name of that institution was not on the list of awards.

The CHAIRMAN said that St. Thomas's Hospital had applied, but the distribution committee had not been able to do anything in the matter because the hospital had not complied with the request of the committee that the accounts should be sent in. He, however, was glad to know that the treasurer of St. Thomas's Hospital had intimated his intention of putting the hospital on the same footing as the other hospitals with regard to its accounts, and its friends might then rest assured that the distribution committee would consider its application in as favourable a way as that of any other hospital.

Dr. GLOVER asked when they might expect the report of the committee inquiring into the question of out-patients. He remarked that last year the question of the out-patients at hospitals was gone into and referred to a committee. In some of the hospitals there had been a marked increase in the number of out-patients during the past year. Thirteen or fourteen of them showed an increase of 20,000.

The CHAIRMAN said his colleagues and himself on the committee felt the importance of the question, but it was a very difficult one to deal with. It had to be regarded from several points of view. There were the opinions of medical men to be considered, the views of the clergy, and the views of persons promoting those institutions known as provident dispensaries. The committee who were considering the question had already met several times, but they had not yet secured all the evidence they wish to have. It would be futile to present a report that did not cover the whole of the subject. He would ask Dr. Glover to exercise a little patience and to accept his statement that the committee were delaying their report in order that it might be more valuable when published.

Sir H. BURDETT and the Hon. SIDNEY HOLLAND also made some remarks, and subsequently the motion was passed unanimously as were also the following motions:—

"That the cordial thanks of the Council be and are hereby given to Sir Sydney H. Waterlow, Bart. (chairman), and to the other members of the committee of distribution, for the special care they have taken this year by the interviewing of numerous deputations, and for the considerable attention bestowed in the preparation of the awards they have recommended."

"That the thanks of the Council be and are hereby given to the editors of newspapers who have pleaded the needs of hospitals and advocated the cause of this Fund with a view to increasing this year's collection."

"That the cordial thanks of the Council are now given to the Right Honourable Sir George Faudel Phillips, Bart., Lord Mayor, who, as president and treasurer, has devoted his valuable time and considerable energy to continue the well-being of the Fund."

Annual General Report of the Committee of Distribution to the Council of the Metropolitan Hospital Sunday Fund.

Your committee have now to report their recommendation of awards to 188 institutions, being an increase of 83 since the first awards were made in 1873, and 8 more than last year. The total amount available for distribution after allowing for liabilities and the usual current expenses is about £40,000. Of this total £39,705 15*s.* 6*d.* is now recommended to be paid to 132 hospitals and 56 dispensaries.

Five per cent. of the total sum collected—viz., about £2000—is set apart to purchase surgical appliances in monthly proportions during the ensuing year.

Your committee recommend that all payments to the Fund after this date be carried to the credit of next year's Fund.

In compliance with an order of the Council, and for the special use of its members, tables of statistics have been prepared as usual, showing an analysis of the number of beds in hospitals, the cost of patients both at hospitals and dispensaries, the proportionate expense of management, as well as other valuable information, and copies are sent to every member of the Council.

The amount available for distribution is, as was naturally expected, rather less than the amount available last year, but your committee feel that it is as large a sum as could be anticipated, having regard to the circumstances of the Jubilee year, in which so strong an appeal has been made in other directions and responded to by the public in favour of our metropolitan hospitals.

For the last twenty-five years the public have nobly responded to the earnest appeal made by ministers of religion in nearly 2000 places of worship on Hospital Sunday. Your committee are of opinion that the amount received this year fully justifies them in the conclusion that the confidence of the public in the Metropolitan Hospital Sunday Fund has in no degree abated, and that the collections in future years, which it is to be hoped will be made under ordinary circumstances, will continue to increase from time to time, as they have done in past years. Appeals have been made from year to year mainly on the ground that it is a religious duty for everyone to give what they can towards the relief and assistance of the sick poor of this great metropolis who are unable to provide such help for themselves, and your committee fully believe that an appeal on these grounds will never be made in vain.

In order to arrive as accurately as possible at the needs and merits of the 188 institutions making applications for a grant from the funds at your disposal, your committee have deemed it necessary to invite the attendance of a deputation from the governing bodies of a much larger number of institutions than in former years. They invited representatives from thirty-eight institutions. In thirty cases deputations were sent to confer with your committee; four of the institutions expressed their willingness to leave themselves in the hands of your committee, and four others took no notice of the invitation. The conferences with the thirty deputations were found to be both useful and mutually instructive. In some cases the objections were removed or modified by the explanations given; in other cases the explanations at the conference only confirmed the impressions your committee had formed.

The work was much facilitated by the fact that the accounts are universally rendered on the uniform system.

ARMY MEDICAL SCHOOL, NETLEY.

THE seventy-fourth session of the Army Medical School, Netley, was brought to a close on Friday, July 30th. The prizes were distributed by Major-General Sir William F. Butler, K.C.B., commanding the South-Eastern District, in the presence of Surgeon-Major-General J. Jameson, C.B., Director-General of the Army Medical Staff, Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S., Surgeon-Major-General Cuffe, C.B., P.M.O. (Portsmouth), Colonel Liddell, A.A.G. Southern District, Surgeon-Major-General C. H. Giraud, formerly P.M.O., Brigade-Surgeon-Lieutenant-General K. McLeod, Sir W. MacCormac, Bart. (President of the Royal College of Surgeons of England), Surgeon-Colonel Tandy, I.M.S. (retired), Surgeon-Major-General W. M. Webb (retired), Surgeon-Captain W. W. Webb (Bengal Army R.P.), Surgeon-Major-General O'Dwyer, P.M.O. (Aldershot), Surgeon-Major-General W. Nash, the professors of the Army Medical School

Digitized by Google

and the military and nursing staff of the Royal Victoria Hospital, and a distinguished company.

The report, which was read by Surgeon-Colonel J. Lane Notter, Professor of Hygiene, stated that the work of the session had been satisfactory, all the surgeons on probation who had undergone the final examination had proved themselves fitted to receive Her Majesty's commission. After distributing the prizes Major-General Sir Wm. Butler delivered an address, which will be found in another column, to the young officers. The Director-General in complimentary terms expressed their indebtedness to Sir William Butler for presenting the prizes and for his valuable and interesting address. Sir Joseph Fayrer then offered his congratulations to the surgeons on probation upon the successes which they had achieved, and specially addressing himself to the young Indian officers spoke of the grand career before them in a service which had produced so many brilliant men, a service which he thought would be even better in the future than it had been in the past. The Principal Medical Officer proposed a vote of thanks to Sir Joseph Fayrer for his valuable remarks and this brought the proceedings to a close. The company was afterwards entertained at luncheon by the officers of the Army Medical Staff.

The following lists show the positions of the young officers recommended for commissions in their respective services:—

ARMY MEDICAL SERVICE.

	Combined marks.		Combined marks.
†S. L. Cummins	4871	J. Poe	3942

§ Gained the first Montefiore Prize of 20 guineas and Bronze Medal.

THE AMERICAN VICTORIA JUBILEE FUND.

WE have received the following with a request for its publication.

The Executive Committee of the American Victoria Jubilee Fund begs to inform the subscribers that the lists for endowing beds in hospitals are now closed, and the total obtained amounts to more than £4300. The surplus to be given to the Prince of Wales's Fund will remain open for the present, and donations to this will be acknowledged by the hon. treasurer, Mr. Walter H. Burns, 22, Old Broad-street. Mrs. Ralph Vivian having written to Sir Fleetwood Edwards asking him to bring to the notice of the Queen the Fund which had been collected in her honour, and to participate in commemorating the sixtieth anniversary of Her Majesty's reign, has received the following reply:—

"Osborne, July 28th, 1897.

"DEAR MRS. VIVIAN,—I have laid your letter of the 25th inst. before the Queen, who desires me to say how touched she is, and also how grateful to yourself and to all those who have contributed to and collected the American Victoria Jubilee Fund. Her Majesty is deeply sensible of the kindness thus evinced, and greatly pleased that the handsome sum thus realised is to be devoted to so good and useful a purpose as the endowment of the beds in the hospitals you name, while the surplus is to be devoted to the Prince of Wales's Fund. The Queen trusts you will be kind enough to express her sincere thanks to all those concerned for their very kind action.

"Believe me, yours very faithfully,

"(Signed FLEETWOOD J. EDWARDS."

THE SEWAGE DIFFICULTY IN MANCHESTER AND SALFORD.

THE treatment and disposal of sewage is a very serious question for all cities and towns, and now that the county councils have power to appoint committees to look after the pollution of rivers and streams we may expect progress in this important matter. The pollution of our rivers ought to be and must be prevented, and whether the effluent be obtained by filtration through land or by treatment with chemicals or both, it must be of such a nature as to be fit to enter these rivers. The time, however, has arrived when it may be considered which is the best method for a particular district. A deputation recently waited on the Parliamentary Secretary of the Local Government Board, their object being to obtain a relaxation of the rule according to which sewage purification must be carried out by means of filtration through land. The deputation wished that artificial filtration should be allowed. The members of the deputation were representatives of the Mersey and Irwell Joint Committee—namely, Sir J. T. Hibbert (chairman), Sir Henry Roscoe (chemical adviser), Mr. R. A. Tatton (chief inspector), Dr. Hewitt, and Mr. J. Brierley.

Sir J. T. Hibbert pointed out the great importance of the subject to the Mersey and Irwell districts, which contained seven county boroughs, with a population of 1,148,000; eleven non-county boroughs, with 249,000 inhabitants; sixty-two urban district councils, ruling 620,000 persons; and ten rural district councils under whose jurisdiction were 127,000 inhabitants. The total rateable value of the district was £9,731,000. The Joint Committee dealt with four rivers—the Mersey, Irwell, Irk, and Medlock—on the banks of which were 394 manufactories. The committee was formed under the Act of 1888 and had almost succeeded in keeping solid matters out of the streams. The committee congratulated themselves that there were schemes everywhere for preventing the pollution of rivers. The policy of the committee was to deal with every authority, large or small, on the same principles. Action had been taken against both Manchester and Salford, but as yet neither had laid a satisfactory scheme before the committee. The committee, knowing the difficulties of Manchester and Salford in getting suitable land for filtration purposes, instructed their chemical adviser (Sir Henry Roscoe) and their chief engineer (Mr. Tatton) to report on the subject of precipitation and filtration. Sir Henry Roscoe reported: "I am of opinion that the adoption of artificial filters is a move in the right direction, especially in the case of large towns having difficulties in acquiring sufficient area of land and of a suitable character for the purification of its sewage. Land filtration, so far as the chemical results are concerned, is superior to artificial filtration. Unfortunately, however, the volume of effluent that can be treated permanently on land is small as compared with the volume that can be filtered by artificial filters." Mr. Tatton stated: "There seems, therefore, to be ample evidence to show that if filters are constructed to conform with the principles which have been laid down satisfactory results may be obtained. The reasonable view to be taken of the matter seems to be that, instead of any hard and fast rule being laid down, each case should be treated on its own merits; that if suitable land can be obtained it should be used, but that if it cannot be got artificial filters should be sanctioned, but with stringent restrictions as to the volume of sewage allowed on a given area." The committee therefore, on the strength of these reports, approached the Local Government Board to have a more open mind on the treatment of sewage.

Sir Henry Roscoe also pointed out that the only land that Manchester could purchase was not fit for a sewage filter and that Salford and other Lancashire towns were in the same fix. In addition to the want of a sufficiently porous soil the climate was against land filtration, and the most suitable land became waterlogged. He argued that each case should be treated on its merits.

Dr. Hewitt stated that Salford's experts said that a satisfactory effluent could be obtained from the sewage by precipitation and artificial filtration. Oldham and Rochdale had taken land only to find it unfit for the purposes of filtration.

The Parliamentary Secretary (Mr. T. W. Russell, M.P.)

Digitized by Google

stated that he had given personal attention to the matter, and had visited Radcliffe and Royton among other places in order to see purification works. The difficulties mentioned had, he said, placed on the Local Government Board a responsibility to examine the whole question afresh. The President (Mr. Chaplin) had authorised him to say that the views of the deputation would receive immediate consideration. It might be necessary to make a full inquiry into the whole subject; but however that might be he could guarantee that the President and officers of the Board would promptly and fully consider everything that had been urged, and, in his opinion, rightly urged.

The importance of sewage disposal in towns and urban districts cannot be concealed. The pollution of rivers must and ought to cease, but to enable public authorities to do this efficiently the Local Government Board must relax its rule as to land filtration and allow such methods to be used as will enable an effluent to be produced that is fit to enter our streams and watercourses. There is no doubt about land filtration giving the best effluent, but precipitation and artificial filtration ought to produce an effluent fit to enter our rivers, and where suitable land is not available local authorities ought to be permitted to adopt such a scheme.

THE SOUDAN CAMPAIGN.

SIR H. KITCHENER knows his own mind and manages to keep his knowledge to himself, in order that the enemy may be quite unprepared for the event until it actually happens. We have been expecting to hear any day that the Nile had risen high enough to permit the continuation of the march from Dongola and its neighbourhood towards the south. The news has now arrived of the capture of Abu Hamed on the morning of the 7th inst. after severe house-to-house fighting with relatively small loss to Major-General Hunter's column, and it is rumoured that the expedition may push straight on to Berber. Life for the English officers has been very trying since Dongola was captured last September, there has been very little leave granted, and the work has been chiefly that of making railroads and forwarding transport. As they go forward on their campaign let us hope that the elements will be kinder to them than last year, and that they may be saved the unnecessary discomforts of dust storms and rain torrents. Cholera is not likely to delay them this summer, for Egypt has been free from it since the autumn. Abu Hamed is rapidly being connected with Wady Halfa by railway, and there will be no difficulty about forwarding transport of all kinds.

By the Nile the army is over 1200 miles from Cairo; and it says something for the efficiency of a handful of British officers that this journey can now be made in two weeks. Fifteen thousand Egyptian soldiers have now been quartered for ten months in the province of Dongola. Most of the food and the whole of the army's equipment and stores have been supplied from Cairo; and while all the necessary supply and transport work has been going on time has been found to lay two railways of a length of nearly 500 miles, and all this without any apparent fuss or trouble. In Egypt the work has been done by three staff officers at Assouan, two at Wady Halfa, and three between Wady Halfa and Dongola; one of these is a colonel and all the others are captains or subalterns, all picked men, certain to be good-tempered under trying circumstances and with that love of responsibility which is the special attribute of so many Englishmen. The health of the troops is uniformly good in the Soudan, in spite of hot days, when every one looks forward to sunset because of the comparatively cool night which braces the men up for the morrow's heat. In the Dongola province the hot months are from May to December, but life is more bearable when the Nile rises and the nights become cooler. The really cool months are from January to April, and then the chief plague is a small black fly, which some of the natives fear so much that they wear on their heads wisps of straw slowly burning to keep off the pest.

Another peculiarity of that part of the Soudan is that the Nile is half a mile wide at Debbeh, and seems to get wider instead of narrower as the traveller ascends it. The climate is healthy enough except for malaria when the Nile is high and later when it is sinking again. If it were not for the healthiness of the desert English officers would hardly have been able to remain for two years and more south of Cairo without any leave. When the whole country is quieted down it is difficult to see who is going to people it. Slavery is no longer permitted, the original inhabitants were killed off by the incursions of Wad el Njuny or have retreated south with the Mahdists. The Egyptian Government has been advised to send pensioners to Dongola, where they might receive land in exchange for part of their pensions. The cultivable portion of Dongola province is 79,000 acres, but the surface under cultivation to-day is only 27,000 acres, and even this can only be worked by old men, women, and children, because the adult males are exceedingly scarce.

According to the latest intelligence, the loss sustained by the Dervishes in their defence of Abu Hamed was considerable, while the casualties on the Egyptian side were, as we have said, relatively insignificant. Two British officers were killed. It is rumoured that the Khalifa is preparing for retreat and is sending his stores from Omdurman in case of the advance of the Egyptian force and the capture of that place.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Cheltenham Urban District.—The Cheltenham public abattoir appears gradually to be growing in favour, and the Council have now obtained a provisional order giving them considerable powers in respect to the closure of existing slaughter-houses. Dr. Garrett furnishes in his report a very interesting account of the colouration of the water in one of the storage reservoirs, that at Dowdeswell, by the growth of an *alga* (Crenothrix polyspora var. Cheltonensis), which gave to the water a markedly red appearance and an unpleasant odour. The water in the reservoir at the time was in a state of considerable stagnation, there being but little fresh water entering it. The filters were unable to separate the organisms, which appear also to have multiplied in the mains. Beyond the red colouration and the disagreeable odour which the organism occasioned no bad results followed, and Dr. Garrett was unable to trace any illness to its consumption. It may be observed that the colouration of the water was most marked during the months of March, April, and May. The colouration of water which occurs from time to time in reservoirs causes much alarm amongst the consumers, and no little anxiety to those who have the management of the waterworks, and those of our readers who are interested in this subject will find in *Public Health* for October, 1896, a very instructive article by Dr. Garrett upon the Cheltenham manifestations, and also a reference to certain occurrences of a similar nature. It may be added that in some cases the covering in of the reservoirs will probably be found a useful preventive measure, and careful filtration is calculated to improve matters. The prevalence of small-pox in Gloucester caused the Cheltenham Sanitary Authority much anxiety, more especially as the baneful influence of Gloucester in the matter of vaccination had not been without its effects in Cheltenham, the guardians having taken up a deplorably weak position in the matter and refused to prosecute defaulters. The sanitary authority, however, took the matter into their own hands and appointed numerous medical practitioners to perform vaccinations in the town free of expense. As a result of this step a very large number of persons were vaccinated or re-vaccinated, and eventually the expenditure thus entailed was allowed, after petitions to the Local Government Board on the matter, to be defrayed by the board of guardians, who in the first instance seem to have been either incapable or undesirous of doing what was obviously their duty. It seems to us that the inhabitants of Cheltenham are much indebted to the medical men of that town for insisting upon the necessity for some prompt action. The justices as well as the guardians of Cheltenham are apparently unwilling to carry out the law in respect to vaccination.

Eccles Urban District.—Dr. J. H. Crocker thinks it not improbable that the pollution of the soil by excrement may be a means by which scarlet fever is spread. He refers to the intestinal and urinary complications of the disease, and

Digitized by Google

raises the question whether the excretions from these parts may not contain the specific poison of the disease. Dr. Crocker also points to the seasonal variations of the disease as tending to support in some degree a thesis that the heating of polluted soil during the late summer months may have something to do with the spread of scarlet fever in certain districts where soil pollution takes place in a marked degree. It will be within the memory of some of our readers that Dr. Niven, of Manchester, last year advanced a similar hypothesis.

Truro Urban District.—The Truro sanitary authority continue to allow the sewage of the locality to pass by numerous outlets into the rivulets which traverse the city, and the tourist is still, at the end of a most picturesque journey on the Fal, made unpleasantly aware of the fact, more especially if he is unfortunate enough to arrive at Truro near the time of low water. The subject of dealing with this nuisance has, Mr. Edward Sharp tells us, been in suspense during the past year, and he believes that the sanitary authority are waiting to see the result of the septic tank process at Exeter. He thinks that if this process proves a success it would be more economical than any other the council have as yet had under their consideration. At the same time, he expresses a hope that measures will be taken to relieve the inhabitants around the West Bridge from the dangerous nuisance arising from the outfall sewers during the summer months.

Eastbourne Urban District.—The general death-rate of this district during 1896 was the lowest on record, being but 10·43 per 1000, or excluding the deaths of non-residents 9·10 per 1000. Dr. W. G. Willoughby discusses the factors which have made for this low death-rate, and while allowing for the operation of such influences as age and sex distribution, &c., he thinks that the low death-rate is in part due to the efforts of the sanitary authority. The water-supply of Eastbourne is still in the hands of a private company, but the ratepayers, by a majority of over 1000, have declared themselves in favour of the acquisition of the water-supply by the corporation, and at the present time there are two Bills before Parliament, one promoted by the corporation and the other by the company. There can be little doubt upon general principles as to the desirability of the water-supply of a community being in the hands of its sanitary authority. Dr. Willoughby, in referring to the report of the Royal Commission on Vaccination, points out that the dissentients have not the courage of their opinions, and that nowhere do they express disbelief in vaccination or advise that the machinery of administration shall be done away with. Under the heading of enteric fever Dr. Willoughby mentions six cases in which oysters were the probable cause. The molluscs in question were traced "*vid* Liverpool to a tidal estuary below a very large town famous for typhoid fever. Other medical officers had traced cases to the same district." Let it be added to the credit of the merchant that he was willing to meet all suggestions and to change the source of his supply. Water-borne enteric fever was conspicuous in Eastbourne during 1896, and at least fifty cases were traced to the consumption of specifically polluted water from the Bourne stream, 45 cases being infected directly from the water, and 7 others contracting the disease from those already infected. Apparently the outburst, which occurred between Sept. 17th and Oct. 27th, was due to the fact that many persons preferred to drink the waters of the Bourne stream in preference to the saline water which was at that time being furnished from the public mains. The sanitary authority seem to have done all in their power to warn the people of the danger which they incurred in drinking the Bourne water, but the notices of caution were torn down each time they were put up. In 1870 an outbreak of enteric fever occurred in connexion with the same stream.

Belfast Urban District.—Dr. Whitaker's report for 1896, just published, shows that, notwithstanding that Belfast is continuing to increase in population the deaths during the past year were less numerous than in 1895; but although the death-rate is below the average of the past five years, it is higher than that of any other city or town in Ireland with the exception of Dublin. The deaths from zymotic diseases are very numerous, but the new hospital for infectious diseases will, when built, tend to diminish the mortality and the prevalence of these diseases by allowing isolation and better treatment of such types of cases. 219 cases of typhoid fever, 169 of whooping-cough, 519 of scarlet fever, and 769 of measles were reported during the year. Whooping-cough caused 215 deaths, measles 205, and typhoid fever 136 during the year. There were 1008 deaths from phthisis and 1640 from diseases of the respiratory organs. The annual birth-rate for the year was 34·5, and the death-rate 23·1. Of the 6953 deaths registered during the year, 2648 were attributed to phthisis and diseases of the respiratory organs, while those from zymotic diseases were 1005, these together making a total of 3653, or more than half of the deaths registered from all causes. It is a noteworthy fact that in Belfast diseases of the respiratory organs caused during the past year nearly one-fourth of the mortality from all causes. The dampness of the soil, the moist climate, and the nature of the industrial employments may be the causes of this high death-rate. The deaths (1008) from phthisis, though numerous, were fewer than in any of the six preceding years, 1894 alone excepted. The mortality from diarrhœa and typhoid fever was less than in the preceding year, but it is not satisfactory to learn that Belfast has the highest death-rate from typhoid fever of any city or town in Ireland. The disease seems to prevail, not only in houses with bad surroundings and defective sanitation, but also in those recently built and properly constructed, where no defects can be detected; nor is the disease confined to any district of the city or to any particular kind of soil. It is, indeed, remarkable, as showing how difficult it is to solve the problem of the causation of typhoid fever, that the district of Belfast in which the fewest number of deaths occurred is Millfield—just the one in which the people are the poorest, the streets the narrowest, the houses the oldest, and the sanitary conditions the most unsatisfactory of any in the city of Belfast. It is curious that the deaths from whooping-cough were the largest number of all the zymotic diseases and were nearly double those from the same disease in 1895. The deaths of infants under one year old were less numerous than in 1895. During the year there were treated in the Royal Hospital 90 cases of infectious diseases with 10 deaths, all from typhoid fever; while in the Union Hospital there were treated 554 cases of infectious diseases with 36 deaths. The Corporation have decided to build a new hospital for infectious diseases, and during the year steady progress has been made in improving the sanitation of the city. It would be a very great addition to Dr. Whitaker's most excellent report if he supplied a map of Belfast showing the boundaries of the various dispensary districts.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5769 births and 5666 deaths were registered during the week ending Aug. 7th. The annual rate of mortality in these towns, which had increased in the five preceding weeks from 14·7 to 22·9 per 1000, further rose last week to 26·9. In London the rate was 25·7 per 1000, while it averaged 27·7 in the thirty-two provincial towns. The lowest rates in these towns were 12·0 in Halifax, 12·3 in Huddersfield, 13·9 in Gateshead, and 16·1 in Sunderland; the highest rates were 34·2 in Nottingham, 35·1 in Sheffield, 41·3 in Liverpool, and 46·2 in Preston. The 5666 deaths included 1994 which were referred to the principal zymotic diseases, against 904 and 1337 in the two preceding weeks; of these, 1543 resulted from diarrhœa, 174 from measles, 62 from diphtheria, 52 from whooping-cough, 34 from scarlet fever, 28 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Swansea, Gateshead, Huddersfield, and Halifax; while they caused the highest rates in Sheffield, Nottingham, Liverpool, and Preston. The greatest mortality from measles occurred in Manchester, Wolverhampton, Blackburn, Salford, and Preston; from whooping-cough in Oldham; and from diarrhœa in Leicester, Birmingham, Portsmouth, Sheffield, Liverpool, and Nottingham. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 62 deaths from diphtheria included 42 in London and 4 in Leicester. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns, and one small-pox patient was under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 7th inst. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the

Digitized by Google

end of the week was 3239, against numbers increasing from 2380 to 3106 on the fourteen preceding Saturdays; 376 new cases were admitted during the week, against 381, 396, and 360 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 158 and 146 in the two preceding weeks, rose again to 156 last week, but were 25 below the corrected average. The causes of 57, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Oldham, Bradford, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Birmingham, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 19·5 and 18 2 per 1000 in the two preceding weeks, rose again to 20·5 during the week ending Aug. 7th, but was 6·4 per 1000 below the mean rate during the same period in the thirty-three large English towns The rates in the eight Scotch towns ranged from 12 8 in Aberdeen and 18·2 in Paisley to 24·2 in Dundee and 26·3 in Leith. The 612 deaths in these towns included 87 which were referred to diarrhœa, 22 to whooping-cough, 19 to measles, 8 to scarlet fever, and 1 to diphtheria. In all, 137 deaths resulted from these principal zymotic diseases, against 100 and 89 in the two preceding weeks. These 137 deaths were equal to an annual rate of 4·6 per 1000, which was 4·9 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 34, 35, and 51 in the three preceding weeks, further rose to 87 last week, of which 65 occurred in Glasgow, 8 in Dundee, and 5 in Paisley. The 22 deaths referred to whooping-cough corresponded with the number in the preceding week, and included 12 in Glasgow, 5 in Leith, and 3 in Dundee. The fatal cases of measles, which had been 15 and 5 in the two preceding weeks, rose again to 19 last week, of which 12 occurred in Leith, 4 in Edinburgh, and 3 in Glasgow. The deaths from scarlet fever, which had been 5 in each of the two preceding weeks, rose to 8 last week, and included 2 in Glasgow and 2 in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 87 and 66 in the two preceding weeks, rose again to 71 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 38, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 24 2 to 22·8 per 1000, further fell to 22·4 during the week ending Aug. 7th. During the past five weeks of the current quarter the death-rate in the city has averaged 22·9 per 1000, the rate during the same period being 20·1 in London and 19·6 in Edinburgh. The 150 deaths registered in Dublin during the week under notice showed a decline of 3 from the number in the preceding week, and included 25 which were referred to the principal zymotic diseases, against 20 and 14 in the two preceding weeks; of these, 18 resulted from diarrhœa, 4 from scarlet fever, 1 from diphtheria, 1 from whooping-cough, and 1 from "fever." These 25 deaths were equal to an annual rate of 3·7 per 1000, the zymotic death-rate during the same period being 8 1 in London and 1·1 in Edinburgh. The fatal cases of diarrhœa, which had increased from 2 to 8 in the three preceding weeks, further rose to 18 last week. The deaths referred to scarlet fever, which had been 2 and 1 in the two preceding weeks, rose again to 4 last week. The mortality from whooping-cough and from "fever" corresponded with that recorded in the preceding week. The 150 deaths in Dublin last week included 40 of infants under one year of age, and 34 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons slightly exceeded the number recorded in the preceding week. Six inquest cases and 4 deaths from violence were registered; and 43, or more than one-fourth, of the deaths occurred in public institutions. The causes of 8, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JULY, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during July in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 11·2 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 7·2, 8·1, and 8·7 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hammersmith, St. George Hanover-square, Hampstead, Stoke Newington, St. Martin-in-the-Fields, Lewisham, and Plumstead; while they showed the largest excess in St. James Westminster, Strand, Holborn, Clerkenwell, St. Luke, Whitechapel, and St. Saviour Southwark. Seven cases of small-pox were notified in London during July, against 11, 10, and 4 in the three preceding months; of these, 2 belonged to City of London, and 1 each to Paddington, St. George Hanover Square, Marylebone, Islington, and Hackney sanitary areas. One small-pox patient was admitted into the Metropolitan Asylum Hospitals during July, and remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a marked further increase upon that recorded in recent months; this disease was proportionally most prevalent in St. James Westminster, St. Giles, Strand, Clerkenwell, Whitechapel, Mile End Old Town, St. Saviour Southwark, and Woolwich sanitary areas. The Metropolitan Asylum Hospitals contained 3064 scarlet fever patients at the end of July, against 2330, 2495, and 2786 at the end of the three preceding months; the weekly admissions averaged 364, against 225, 258, and 272 in the three preceding months. The prevalence of diphtheria in London showed a further increase upon that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Clerkenwell, St. Luke, Mile End Old Town, St. Saviour Southwark, St. George Southwark, and Camberwell. There were 957 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of July, against 764, 783, and 864 at the end of the three preceding months; the weekly admissions averaged 139, against 108 and 125 in the two preceding months. The prevalence of enteric fever in London also showed a slight further increase upon that recorded in recent months; this disease was proportionally most prevalent in St. James Westminster, Bethnal Green, Whitechapel, St. George Southwark, and Greenwich sanitary areas. Erysipelas showed the highest proportional prevalence in Strand, Shoreditch, Bethnal Green, Whitechapel, and Newington sanitary areas. The 14 cases of puerperal fever notified in London during July included 2 in Fulham, 2 in Hackney, and 2 in Wandsworth sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, July 31st, the deaths of 6261 persons belonging to London were registered, equal to an annual rate of 18·3 per 1000, against 16·6, 14 9, and 13 9 in the three preceding months. The lowest death-rates during July in the various sanitary areas were 9·8 in Lewisham (excluding Penge), 10 0 in Plumstead, 11·1 in Hampstead, 11 6 in Lee, 11·7 in Wandsworth, 13·9 in Paddington, and 14·1 in Stoke Newington; the highest rates were 25·6 in Holborn, 26·1 in St. George Southwark, 31·3 in St. George-in-the-East, 31 9 in St. Saviour Southwark, 32·8 in Limehouse, and 33·2 in St. Luke. During the four weeks of July 1428 deaths were referred to the principal zymotic diseases in London; of these, 939 resulted from diarrhœa, 160 from diphtheria, 136 from whooping-cough, 99 from measles, 68 from scarlet fever, 25 from enteric fever, and 1 from small-pox. These 1428 deaths were equal to an annual rate of 4·2 per 1000. The lowest zymotic death-rates were recorded in St. George Hanover-square, Hampstead, Lewisham, Woolwich, Lee, and Plumstead; and the highest rates in St. Luke, Shoreditch, St. George-in-the-East, Limehouse, St. George Southwark, and Newington sanitary areas. The single fatal case of small-pox belonged

to City of London sanitary area. The 99 deaths from measles were less than half of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Clerkenwell, St. Luke, St. George Southwark, and Bermondsey sanitary areas. The 68 fatal cases of scarlet fever were 8 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. Giles, St. Luke, and St. Saviour Southwark. The 160 deaths from diphtheria were 13 above the corrected average number; the mortality from this disease was highest in Holborn, Clerkenwell, St. Luke, Limehouse, St. George Southwark, Greenwich, and Lee sanitary areas. The 136 fatal cases of whooping-cough were 50 below the corrected average number; this disease was proportionally most fatal in Hammersmith, Clerkenwell, City of London, Limehouse, and St. George Southwark sanitary areas. The 25 deaths referred to enteric fever were 10 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 939 fatal cases of diarrhœa were 99 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Chelsea, Shoreditch, St. George-in-the-East, St. George Southwark, and Newington. In conclusion, it may be stated that the mortality in London during July from these principal zymotic diseases was nearly 7 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 221 per 1000 during July, and exceeded the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Paddington, St. George Hanover-square, Islington, Lewisham, Lee, and Plumstead; and the highest rates in Westminster, St. Martin-in-the-Fields, Strand, Shoreditch, St. George-in-the-East, Limehouse, St. Saviour Southwark, and Newington.

THE SERVICES.

ARMY MEDICAL STAFF.

THE under-mentioned Surgeon-Captains to be Surgeon-Majors:—James H. Curtis, Sydney G. Allen, James S. Green, Cecil A. Lane, Philip C. H. Gordon, Llewellyn T. M. Nash, John H. Brannigan, Michael O'Halloran, Claude S. Sparkes, William H. Pinches, James H. Daly, George J. A. Tuke, Frederick J. Greig, Henry D. Rowan, Howard Carr, Harold G. Hathaway, Benjamin A. Maturin, Thomas Daly, Michael J. Sexton, Herbert E. Cree, William H. Starr, Alexander A. Sutton, Alfred P. H. Giffiths, Frederick J. W. Stoney, and John T. Burke.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Lieutenant J. C. Robertson, Bengal, are placed at the disposal of the Foreign Department. The services of Brigade-Surgeon-Lieutenant-Colonel G. W. R. Hay are placed temporarily at the disposal of the Government of India in the Military Department. The services of Surgeon-Captain C. Milne are replaced at the disposal of the Government of India. The services of Surgeon-Lieutenant H. J. Walton are replaced at the disposal of the Government of India in the Home Department. The services of Surgeon-Lieutenant H. A. Dickson are replaced at the disposal of the Government of India in the Home Department. Surgeon-Lieutenant H. A. F. Knapton is appointed to the medical charge of the Railway Inspection duty at Kalyan.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon Charles Francis Newland has been placed on the retired list of his rank at his own request.

VOLUNTEER CORPS.

Royal Engineers (Volunteers): 1st London: Surgeon-Lieutenant R. Buswell resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle:* 2nd Volunteer Battalion the Queen's (Royal West Surrey Regiment): Honorary Assistant Surgeon J. A. Lorimer resigns his appointment. 3rd Volunteer Battalion the King's (Liverpool Regiment): Herbert Harrison Marsden, gent., to be Surgeon-Lieutenant. 1st (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Lieutenant-Colonel D. B. Balding resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 1st Volunteer Battalion the Royal Welsh Fusiliers: Surgeon-Lieutenant J. A. Eyton-Jones resigns his commission. 3rd Volunteer Battalion the Royal Welsh Fusiliers: Surgeon-Captain T. E. Jones resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: The services of Surgeon-Captain W. E. St. M. Raw are dispensed with; Surgeon-Lieutenant J. Harper, M.D., to be Surgeon-Captain.

THE MEDICAL SERVICES.

The following is a list of candidates for Her Majesty's Army Medical Staff and the Indian Medical Service who were successful at the recent competitive examination held in London:—

THE HEALTH OF THE ARMY IN INDIA.

The Anglo-Indian papers publish the orders which have been issued by the Commander-in-Chief in India in regard to the prevalence of venereal disease. After calling attention to the facts set forth in the official report of Earl Onslow's committee, and dwelling upon their extreme gravity, Sir George White makes a strong appeal to the soldiers serving in India to avoid vicious connexions, and warns them of the deplorable consequences likely to result therefrom. He also calls upon officers commanding regiments and all regimental and medical officers not to stand aloof as spectators, but to do everything in their power to draw the men from the bazaars and other neighbourhoods frequented by loose women, and points out a variety of ways in which their influence may be brought to bear upon soldiers, adding that disciplinary restrictions may be enforced where local circumstances render these desirable. The draft of the new Cantonment Rules has been published in the *Gazette of India*.

THE HEALTH OF MEDICAL OFFICERS IN THE BOMBAY PRESIDENCY.

According to the *Times of India* of the 23rd ult. there is a good deal of sickness among the medical staff, both of the British and Indian services, in the Bombay Presidency. Owing to the medical services being so short-handed at the present time it is very difficult to give them leave. The work that has been imposed upon the medical services of late, owing to the exceptional state of things in Bombay and India, has been great.

THE SEAFORTH HIGHLANDERS IN CRETE.

Among the items of intelligence from Crete it is stated that sickness (fever) has been unduly prevalent of late in the detachment of the Seaforth Highlanders, and that the detachment is moving its quarters in consequence from Canea to a more healthy site at Halefra.

FOREIGN UNIVERSITY INTELLIGENCE.—*Florence:* Dr. Galeotti has qualified as *privat-docent* of General Pathology, Dr. U. Flora as *privat-docent* of Medical Pathology, and Dr. U. Mantegazza as *privat-docent* of Dermatology.—*Siena:* Dr. Angelo Mannotti, of Pisa, has been recognised as *privat-docent* in Surgery.—*Würzburg:* Dr. Casimir Stubenrath has been recognised as *privat-docent* in Forensic Medicine, and Dr. Gustav Wolf, of Carlsruhe, as *privat-docent* of Psychiatrics. Dr. Stöhr, of Zürich, has been appointed to the chair of Anatomy.

"Audi alteram partem."

"HOSPITAL ABUSE."

To the Editors of THE LANCET.

SIRS,—The article by your Special Commissioner on "Hospital Abuse in Birmingham," published in your issue of July 31st, only came under my notice a day or two ago, or I should have replied earlier to his grave reflections upon our citizens generally, and the local members of the medical profession in particular. Without impugning your Commissioner's good faith for a single moment, I do not hesitate to say that the charges he makes against us are unjust in the last degree, more especially as they are entirely unsupported by evidence of any kind. It is really monstrous that a casual visitor to our city should take upon himself to assert that the vast majority of our population are not born and bred here (how can he possibly know?), and are only attracted here by sordid motives, with the intention of hurrying away again as soon as they have "made their pile," and that then, having committed himself to that view, he should proceed to convict the medical men of a similar taint and to attribute the failure of hospital reform largely to this fact.

The efforts of THE LANCET in the cause of hospital reform deserve and command the same sympathy here as elsewhere, though we have special difficulties to contend with; but the value and authority of such efforts can only be impaired by the importation into your inquiry of reckless personal imputations which are entirely unsubstantiated. If you desire the coöperation of the medical profession in this city in your laudable endeavour—as I feel sure you do—I venture to think that you will do well to repudiate and withdraw without delay the statements of which Dr. Saundby and I complain.—I am, Sirs, yours faithfully,

Aug. 10th, 1897. ALFRED H. CARTER, M.D., F.R.C.P.

To the Editors of THE LANCET.

SIRS,—You do me too much honour by devoting an entire leading article to my poor self, but as you complain of my omission to "exhibit the cowardice, cruelty, and misrepresentation of which I complain," and as you also accuse me of neglecting the courtesies of debate, I must ask from your justice a sufficient space for reply.

If your readers will only turn to the article in question[1] they will have no difficulty in seeing the nature of the charges against the citizens of Birmingham, and the medical profession in Birmingham, which you would have been more honoured in disavowing than in defending. This article asserts that the citizens of Birmingham are mostly strangers who "rush in from the outside in the eager hunt for money. They simply strive to make their pile and haste away again. Among such a population it is difficult to spread altruistic ideas; it is a wild endeavour all round after business each for himself, and but few pause to consider what are their duties to society." It is true that many citizens of Birmingham are not natives of the place, but it is not only not true, it is ridiculous, to say that these adopted citizens are not active participators in our public life. Birmingham has justly acquired a world-wide reputation for its municipal institutions and for the public spirit of its citizens, and among those who have done most for the city have been these "people from the outside." I need name only Mr. Chamberlain, Sir Josiah Mason, Sir John Jaffray, and Mr. Jesse Collings as instances to the point. A city which has shown so much public spirit that it has been often quoted as a model of municipal progress, which has even earned the perhaps too laudatory title of the best-governed city in the world, but which certainly has within the short space of a generation transformed itself, re-modeled and re-built its institutions so as to be a pattern and example to other places, can afford to disregard the ill-informed opinions you have so rashly published. I leave it to impartial judges to say whether such charges inflict more damage on Birmingham or on its critic.

[1] THE LANCET, July 31st, 1897, p. 284.

But your article proceeds to say that "this spirit"—i.e., of selfish money-grabbing—"also animates more or less—let us hope very much less—the medical profession, and therefore it has been *particularly difficult* to group the medical men together and get them to put their *personal interest* in the background so as to defend the position of the profession as a whole." The italics are mine; but surely this accusation is so serious that if it be untrue it is not undeserving of the title "monstrous" or of being styled a "cowardly cruel libel," and I say that it is not true, but the very opposite of the truth.

There is more to follow. We are told that "in Birmingham it suffices for one set of men to attempt to form an organisation or to start a movement, and at once another set of men are stirred with suspicions, or even moved to open hostility. Instead of inquiring what good cause is to be promoted, they will strive to find out that some personal interest is to be served." I seek in vain either in your article or in my recollection of the medical history of this city for the last twenty years any justification for these charges. To warrant them there surely should have been at least some one serious occasion upon which we showed ourselves unable to coöperate for the common good. "In smaller towns," we are told, "where the spirit of commercialism is not so rampant, organisation has been more easily accomplished." May one not suspect that the size of the town has more than the spirit of commercialism to do with this simplicity of organisation? But where is the town in which this boasted organisation has achieved any notable success? I know only of those in which it has made the state of the profession worse than before. Are we to be blamed because we do not move until we see a prospect of doing so with advantage?

The charge of want of organisation is as ridiculous as is the explanation given of the failure of the report of the Hospital Reform Committee. These only go to show how ill-informed you have been, and upon what an untrustworthy basis your charges have been laid. I cannot trespass farther on your space, but if you will withdraw the charges of which I complain I shall have much pleasure in telling your readers why the report of the Hospital Reform Committee failed.

With respect to your accusation of want of courtesy, I have only to add that if in rebutting accusations which are false and injurious I have been wanting in the courtesy due to those who make such accusations I apologise, but I leave it to the judgment of the profession to say whether such charges should ever have been published and defended in the editorial columns of THE LANCET.

I am, Sirs, yours faithfully,

Birmingham, Aug. 9th, 1897. ROBERT SAUNDBY.

To the Editors of THE LANCET.

SIRS,—I read and re-read your correspondent's article on Hospital Abuse in Birmingham, and I failed to find anything that deserved the epithets used by Dr. Saundby in his letter. For some reason or other Dr. Saundby has not thought fit to lend any countenance to the discussion of a question which has been agitating men's minds for the past thirty years—a question, I may add, that statesmen of the highest eminence and medical men of the highest standing have expressed their sympathy with. Your correspondent does not need any testimonials from any member of the profession, but all those who have carefully perused his articles will bear me out when I say that he has succeeded in presenting your readers with a statesman-like view of the whole question. He has pointed out from time to time that hospitals are abused, not only by the public, but by general practitioners.

It has been a source of gratification to my association to find that at all of their local meetings the many members of the hospital staffs have been in sympathy with our objects and have expressed their determination to bring about a reform of the present unsatisfactory condition of affairs. It is only by a free and frank discussion of this pressing problem that we can hope to arrive at a satisfactory solution; and the continuation of your correspondent's letters will undoubtedly help very materially in this direction.

I am, Sirs, your obedient servant,

T. GARRETT HORDER,

Cardiff, Aug. 9th, 1897. Hon. Sec., Hospital Reform Association.

MEDICAL AID ASSOCIATIONS AND THE ETHICAL POSITION OF THEIR MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—I am glad to see in THE LANCET of July 31st some fair and candid criticism of the Loughborough Medical Aid Association. It is evidently a "sweating association," but it is something worse than this. In common with insurance medical clubs it upholds the idea of the exploitation of medical diplomas by lay persons. It always surprises me that our General Medical Council, which is now so much awake to the evil of employment of unqualified assistants, does not also recognise the fact that committees and syndicates can practise for gain under the "cover" of qualified practitioners. The one abuse I hold to be equally "infamous in a professional respect" with the other. It would be practically useless for one or two Colleges, more especially London ones, to take action or express pious opinions in this matter. The men who take these positions are not usually associated with those Colleges. Concerted action of all the qualifying bodies might be of some use, but I still think our strongest point is the action which must in time emanate from the Council. In bringing this matter forward the local unions now being formed may do much, and the British Medical Association, if it lived up to its ideal, might do more. This is no "puny battle." It is one which means victory, self-respect, and the favourable regard of the public, or defeat, degradation, and ill-paid drudgery for the bulk of the profession.

There will always be "wastrels" in every profession. Alcoholic derelicts are not peculiar to our own. They are quite as numerous in the Church and the Law. There will always be men ready to take a "living" in any shape, even though the position be equivalent to that of the caretaker of a tied public-house. It is for us to see that such temptations shall not be offered, that the conditions of medical labour shall be respectable, and that our "derelicts" shall, if possible, reform themselves under rules of service which shall not be calculated to confirm, or even engender, habits of excess. In this matter I have great faith in the Press, more especially in THE LANCET. The pen is mightier than the British Medical Association or the General Medical Council, and I feel assured that your constant advocacy of a good cause will not be thrown away.

I am, Sirs, your obedient servant,

Loughborough, July 30th, 1897. J. B. PIKE.

WHAT A LEPROSY CONGRESS SHOULD BE.

To the Editors of THE LANCET.

SIRS,—In December, 1895, Dr. Goldschmidt and myself began to work for the formation of an international committee against leprosy. It was intended that every Government should appoint an official delegate to become a member of a permanent committee. These delegates were to meet with a congress of leprologists and representatives of the Church and Red Cross. After the congress had been held it was thought that, if nothing else came out of it, this permanent committee would remain active for ever after. Bearing in mind that the discoverer of the leper bacillus has not done one thing for the solution of the universal leper problem, that all the influence of missionaries has been of no avail, and that the disease seems incurable, we thought that no other hope remained but the establishment of the only system which not only promises success, but allows us a certain expectation of it—that is, isolation. This can only be done by edicts of every Government issued simultaneously. To obtain these edicts it was necessary to sound every Government and find out whether it would be willing to appoint an official delegate to our congress, not to be a mere delegate to that congress alone, whose function should stop with the congress, but to form a body active after the dissolution of the congress. Such efforts demanded time. While we were engaged in this work, and when we had already received many assurances of sympathy and promises of Governmental assistance, Dr. Ehlers, of Copenhagen, thinking that we were starting a mere leprosy congress, one of those medical congresses of which the world has seen so many, with the approval of some Berlin men, sent out an invitation to all leprologists to meet in conference at Berlin, and he expressly stated, publicly and in private correspondence, that *he* did not want Government delegates in Berlin. Armauer Hansen also declared that he could not see what good such a committee could do. Neither of these men could understand what our real object was, and Hansen could not see why we did not issue our invitation at once. Had we intended to have a simple conference of learned men and an ephemeral committee of official delegates, we could have issued our call long before Dr. Ehlers bethought himself of taking advantage of the necessary slowness of a very serious enterprise and of issuing his call for a very ordinary and, by its very nature, fruitless debate. Even afterwards, when to placate us the Berlin men deigned to send out invitations through the German Government to other Governments to appoint official delegates, even then they could not get hold of the true idea of our congress. Their official delegates will be appointed without any view to permanency. Had these men joined us, waited and worked with us patiently, we should have obtained that permanent committee. At any rate, it was an object worthy of all the energies of earnest men. The official delegates would have returned home, and each in his own country would have occupied a position endowed with power to act in all matters of leprosy. Thus isolation, if ordered by the congress, would have been effectively declared to the world to be the only sure means for the eradication of leprosy. These men, each in his own country, would have had authority for taking the measures suitable to their countries respectively. When the conference of Berlin has burst like a soap bubble, the necessity for another serious, earnest, practical congress will be felt—a congress like the one which has been delineated above, and which Dr. Goldschmidt and myself have proposed and worked for.

I am, Sirs, yours faithfully,

New York, Aug. 4th, 1897. ALBERT S. ASHMEAD, M.D.

THE INCIDENCE OF MATING.

To the Editors of THE LANCET.

SIRS,—When we find weak native elements clubbing together with their fellows it is reasonable to argue that a subtle law is in operation, governing and regulating such phenomena. It is noteworthy to find that if malignant or tuberculous disease or a neurosis is proved to exist in a husband or wife the coincident occurrence of the same ailment can by diligent hunting be discovered in the members of his or her colleague's family. When such insurgent types join hands the propagation of anarchy might be looked for, but, fortunately for the race, the dispensation of variation interposes. In two catalogues of thirty-two and twelve marriages respectively I find the coupling together of eighty-eight persons who bore no blood relationships towards one another. Regarding the first list, in every instance the individual had annexed to him or her such neurotic impedimenta as insanity, apoplexy, paralysis, epilepsy, tetanus, diabetes, spasmodic asthma, chorea, psoriasis, hysteria, dipsomania, suicide, and homicide. ..... In the second list the members composing it had not only separate entities, but were born in different parts and were all stained with the taint of cancerous disease.

* * * * * * *

The following history of a family will serve to indicate how the members of it sought out and obtained affinities who were at one period apparently strangers to them and to one another, and who dwelt in parts having no contiguity. A man immigrated to this colony more than fifty years ago and married a woman whose predisposition favoured a neurosis or the development of tuberculous disease. After his arrival here his mother and sister died from cancerous diseases and his two brothers became insane in Scotland. In this colony he and his three daughters became afflicted with malignant disease, and he died from this disorder. One son's wife died in a distant colony from cancer of the throat, and he then married the sole survivor of a phthisical family who is apparently healthy; he has now perished from decline. Another son married a girl whose father had had his lip (or a portion of it) excised; another son's mother-in-law died from cancer of the breast; a daughter married a man whose brother perished from malignant disease of the stomach; six other descendants of the immigrant are unimpaired in

Digitized by Google

health. Another case was as follows. A woman developed malignant diseases of the ovary and other organs in the pelvic basin, any previous knowledge of such a disorder being disavowed by her relatives. About two years after her death her widower, who was a hearty man to all appearance, contracted epithelioma; he then admitted that his father had died from an abdominal tumour in another country about thirty years previously and that his sister had died from "internal complaint." Almost contemporaneously the intimate lady friend of the lady and widower, who was engaged to be married to the latter, developed scirrhus, and, as usual, denial was made of any historical taint. The associate of husband and wife dwelt in a part situated miles away from her fellow sufferers. The following is an additional instance. In the case of a female who had resided in this colony for fifteen years easily recognised malignant disease appeared after certain dyspeptic symptoms, coupled with alternate diarrhœa and sickness, had prevailed for some days. She had always been strong, but her only son had been killed in a tragic fashion, and her illness dated from the crisis of the catastrophe. As usual, denials were made of the pre-existence of similar disease in the members of her family, but the coincident was announced in the person of her husband's sister, who was not a blood relative and who had never been to the antipodes, but had died from cancer at the other side of the globe a few months previously.

* * * * * * *

To sum up. A definite material organism in every individual has a concomitant mind depending upon it, and in pathology, agreement or a law of similarity obtains, which, operating as the attraction of cohesion, governs the incidence of mating. I am, Sirs, yours faithfully,

LAVINGTON G. THOMPSON, M.D. Aberd.

Launceston, Tasmania, June, 1897.

*** On account of the great length of the original communication we have been compelled slightly to curtail the introductory part and to omit several of the illustrative cases.—ED. L.

"MEDICAL GEOGRAPHY AS AN AID TO CLINICAL MEDICINE."

To the Editors of THE LANCET.

SIRS,—Will you kindly let the following corrections in my address on Medical Geography, published in THE LANCET of July 31st, be made in your next issue. Read at p. 238, col. 2, third line from top: "but this is due to the fact that cancer affects the river-valley systems, which protect and shelter the phthisical, whilst they harbour the *materies morbi* of rheumatism, and its too frequent sequel heart disease," instead of what now stands; p. 239, col. 1, line 35, instead of 92, read *92·3*; and at line 37, instead of "a little over 12" read *10·8*. I am, Sirs, yours faithfully,

Aug. 11th, 1897. ALFRED HAVILAND.

MEDICAL MAGISTRATE.—Mr. Charles Harrison M.D. St. And., M.R C S. Eng., D.P.H. Camb., has been placed on the Commission of the Peace for the city of Lincoln.

CLAYTON HOSPITAL, WAKEFIELD.—The 110th annual meeting of the Clayton Hospital, Wakefield, was held on the premises on July 28th, Mr. Tew, J.P., the President, being in the chair. The report showed that during the past year there had been 654 in-patients and 3960 out-patients. Both the income and the expenditure had been materially less than in the preceding year. Mr. J. W. Walker, one of the surgeons, read a letter from Mrs. Louisa Milnes-Gaskell, widow of Colonel Milnes-Gaskell, J.P., of Lupset Hall, near Wakefield, the purport of the letter being that on account of the great interest which her late husband felt in the Clayton Hospital she offered to enlarge the wing containing the present Gaskell Ward so as to make an upper and a lower ward, each with beds for sixteen patients. A portrait of the late Mr. Samuel Fozzard Harrison, who not long ago bequeathed nearly £25 000 to the hospital, was subsequently unveiled by Dr. T. G. Wright, the senior physician. The portrait has been presented to the hospital by Colonel W. W. Clapham, of Manchester, and will be hung in the board-room.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

XII.—BIRMINGHAM *(continued)*.[1]

Abuse at the General Hospital.—The Measures taken at the Queen's Hospital.—The General Dispensary as the Chief Offender.—The Committee Captured by the Workmen.

THE attempt at hospital reform which was initiated under the most favourable auspices some seven years ago having, nevertheless, and as described, utterly collapsed, it is now necessary to describe the present state of affairs. My first care was to call on one of the visiting staff of the General Hospital, at which hospital the ticket system is in force except for urgency cases and accidents. If, however, any member of the staff thinks that a patient can afford to pay for medical attendance the patient can be referred to the office for inquiry. But this is not done often. There are too many patients for the members of the staff to think about such questions. It takes less time to prescribe than to inquire into the social position of the patient. That the majority of the applicants are poor people is proved by the fact that their numbers fluctuate according to the condition of trade. At the present moment trade is more prosperous, so the number of patients in the out-door department has considerably decreased, thus suggesting that many of the working classes do pay for private medical advice when they are in full employment. As for the proposal made with a view to reduce the number of out-patients, it was frankly admitted that the hospital visiting staff, but more especially the surgeons, liked to have a large number of out-patients.

That cases of abuse existed at the General Hospital was not denied, and tickets were often very injudiciously distributed. Thus an in-patient, on being told that he would soon have to leave as the time generally allowed was almost terminated, replied that he had "instructed his solicitor to procure him a second ticket." In the out-patients' department a young girl was receiving explanations as to the street where she should go so as to obtain an elastic stocking when she replied, "Oh, do not bother; the cabman will know!" But whatever fault might be found with the General Hospital for treating patients who could afford to pay my informant was of opinion that far greater abuse of this description prevailed among the frequenters of the Birmingham General Dispensary. Further, he complained that the word "charity" had been left out of the recommendation tickets, and the words "a proper subject for relief" substituted. This spread the idea that hospitals were not charitable institutions and accounted for much of the abuse. This conception was still further accentuated by those hospitals which compelled the patients to pay registration fees. On account of subscribing to the Hospital Saturday Fund and the registration fees there were not a few working people who imagined that they only received from the hospitals that for which they had made a full and sufficient payment.

Calling on one of the leading surgeons who has taken a prominent part in the agitation for hospital reform, but who is not on the staff of the General Hospital, I found that he was disposed to criticise severely this institution. A new building for the General Hospital was now almost completed, and it was said that the cost would amount to about £600 per bed. How could the medical staff ask for economy in the face of such conditions? If they objected to this luxurious display it might hurt the feelings of the wealthy and eminent laymen who sat on the hospital committee. It was a source of personal satisfaction to these committee men to be concerned in the building of a palatial and model hospital, and they were not likely to study and understand what might be the economic consequences on the interests of the

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; (9) May 8th, 1897, France, United Action and Legislative Action; (10) May 15th, 1897, Leicester; (11) June 5th, 1897, Nottingham; and (12) July 31st, 1897, Birmingham.

Digitized by Google

profession as a whole. The principal abuse arose in the out-patients' department. At the Queen's Hospital a superintendent registered the applicants and made inquiries as to their social condition. But if this prevented some well-to-do people from coming to the hospital it did not prevent any number of trivial cases from among the poorer classes. This was the worse abuse. Because a workman paid a penny a week to the Hospital Saturday Fund he imagined he had the right to the services of an expert for the treatment of a slight boil. Every slight accident—even the case of a child who runs a pin into his finger—is at once brought to the hospital. That this is not a necessity is proved by the fact that these trivial cases all come from the immediate neighbourhood of the hospital. If the trivial ailment or accident occurs at a distance of more than half a mile, then the persons concerned have no trouble in getting out of the difficulty without resorting to a hospital. Thus people go to the hospital, not because they cannot do otherwise, but simply because it is convenient and inexpensive. The middle classes also think that they have a right to the services of the hospitals for any accident, even if it is but a simple sprain. Many people who possess ample means believe when they are hurt that they have a sacred right to go to the nearest hospital, and not only have their wounds dressed, but carry off with them bandages and dressing without ever pausing to think that these things cost money. Yet only a lamentably small proportion of the well-to-do classes subscribe to the hospitals. On analysing the subscription-lists to the various medical charities the same names will often occur on three, and even five, different lists, and generally these are the names of persons who are not very rich. It is those whose means are limited who have the highest sense of their public duties. The wealthier classes show far greater selfishness. The number who could subscribe and do not subscribe constitute a large majority. The public also does not sufficiently understand that a hospital is not merely a building; what constitutes the value of a hospital is the quality, not the quantity, of the work done. Cases were mentioned of boys who were on the out-patients' list for five weeks and yet they only suffered from boils. To swell out the list of cases treated by the record of such petty ailments was no real credit to a hospital; but the public does not enter into details, and being deceived by such figures concludes, on the contrary, that the hospital is doing an immense amount of work and therefore that larger subscriptions should be given. These evils would never be overcome till the members of the profession formed themselves into a union, and this must be a fighting union. There had been quite enough talk and discussion as to the grievances, it was now only necessary to study what means of action were available.

On going to the Queen's Hospital I found that the superintendent, Mr. Hulme, had taken his task of preventing abuse seriously to heart. Nevertheless, he was obliged to acknowledge that being alone in the work, and having no machinery for following up the inquiries made at the hospital by inquiries made at the dwellings of the applicants, he occasionally let through persons who were not fit recipients of charity. When a patient goes to the Queen's Hospital he has to enter Mr. Hulme's office and must there give his name, age, address, describe the nature of his employment, and the name and address of his employer. Then he must state the number of his family and what is the available income of his family as a whole. From the address given and the nature of the employment the superintendent can generally form a rough estimate of what the income is likely to be. Thus, on the day of my visit, a young woman, who stated that she was twenty-three years old, and yet had not been out to work anywhere, was refused admittance. Her father earned two guineas a week, and some of his sons were at work, and also contributed to the family income. Such a patient could well be treated through the agency of a provident society or by a private practitioner, particularly if it was a slight case involving no great expense.

My next visit was to a general practitioner who had been for some considerable time on the staff of the Birmingham General Dispensary. He expressed himself energetically against this institution as inflicting great injury on the medical profession. Persons who could well afford to pay medical fees were constantly resorting to this charity. There was often a handsome sprinkling of seal-skin jackets in the patients' waiting room. Taking the Ladywood Branch, for which he had worked, he pointed out how the immense increase of patients was quite out of proportion with the increase of the population. Thus in 1888 there were about 4000 patients attending at the Ladywood Branch. At the end of the year there were about 4800. The population of the district has not increased 10 per cent. in ten years, yet in 1890 there were some 6000 patients, and in 1891 about 6900. At that time some of the outlying districts were taken off the relief lists and the numbers fell, but nevertheless they soon rose again to about 7000. The dispensary is much abused by a class just above the working class—men who earn £2 and more a week. On one occasion some inquiries were made, and during the course of a week 25 per cent. of the patients attending the Ladywood Branch stated that they had more than £100 a year. One case was mentioned of a father who earned £2 a week and his children earned 12*s*., 7*s*., and 4*s*. respectively. He argued that his children were too poor to pay medical fees, and he did not see why he should pay them. Some 7000 tickets had been given away in a year, and so great was the crush of patients that one of the medical officers attached to this branch declared that he had seen as many as 120 patients in a couple of hours. Such hurried work, it cannot be repeated too often, especially by the press the general public read, is not only degrading to the medical profession, but dangerous to the patients. No medical man, however competent, can avoid making mistakes when he has so little time to devote to each patient. This is the side of the question which most affects the general public, and therefore should be specially insisted upon by all who are seeking to reform the present abuses. There are now two medical officers at the Ladywood Branch, so the crush of patients is not so great, but the abuse continued a long time before this improvement was effected. When this branch was first opened a local practitioner declared that it had reduced his income to the extent of £100 a year; and two other practitioners, who have both been in the service of this branch, declared to me that, in their opinion, there was far more abuse at the General Dispensary than among the members of benefit societies and other clubs. Then the fact that the dispensary medical officers visit the patients at their own homes causes a great injury to the general practitioner. Under these circumstances a person with limited means, but still able to pay medical fees for ordinary cases of illness, is strongly tempted to go to the General Dispensary. He will go there, not as the recipient of a charity, but as the purchaser of a recommendation ticket. He will therefore think that he has paid for what he gets. He will not pause to consider if the pay is sufficient; that is the business of those who sell the tickets, and care has been taken to efface the word "charity" from these tickets.

Some years ago the Birmingham General Dispensary published the following announcement: "Notice to workmen's clubs, schools, mothers' meetings, &c. The attention of the committee having been called to the objection felt by workmen's and other societies to the words 'object of charity' appearing in the tickets available for the use of their own members, and paid for by their own contributions, they have decided in future to omit such words from these tickets, retaining them on those issued to subscribers for purely charitable objects. Six tickets will be given for each annual guinea subscription as heretofore, but all extra supernumerary tickets will be charged 4*s*. each."

This simply meant that for certain persons the dispensary was to cease to be a charitable institution and become a provident dispensary without, however, inculcating any true principle of providence. The theory of a provident dispensary is the same as that of insurances against death or accidents. When a person is in sound health he pays generally a penny a week so as to secure medical aid when he is ill. But here it is not necessary to make any provision against a rainy day. It suffices to have 4*s*. at the time of illness to buy a ticket and thus secure the medical aid. Therefore, an institution which was founded as a charitable dispensary, and as such generously supported by the donations and the legacies of the benevolent, degenerated into the position of a sick club, which enables persons devoid of scruple to obtain relief on terms that compete disastrously with the general practitioner. Instead of substituting the words "deserving of medical relief" for the old words "real objects of charity" these latter should not only have been maintained, but printed in big, bold, red letters. How the trade in tickets increased was shown by the committee of the General Dispensary. In their report of January, 1888,

Digitized by Google

the following passage occurs: "Having regard to these figures [an analysis of the subscriptions made by their own secretary] and to other information which has reached them they [the committee] are led to believe that from one-fourth to one-third of the dispensary tickets issued are used by the persons (or by the families of persons) who have contributed to the cost of the tickets, and who cannot, therefore, fairly be described as 'objects of charity,' or as the class of persons for whose benefit charitable subscriptions and donations are usually intended. There is reason to believe that this irregular practice is especially prevalent with the extra tickets, and the tendency to increase in this class of tickets is very marked. Thus in 1885 these extra tickets were but 5 per cent. of the whole, in 1875·23 per cent., and at present they are 36 per cent."

Since that time the management of the General Dispensary has to a large extent fallen into the hands of the working-men subscribers. In 1873 the Birmingham Hospital Saturday Fund gave the General Dispensary a donation of £281; in 1896 this sum was increased to £600. As donors, the representatives of the workmen had votes for the election of the members of the committee of management. At the annual meeting held in the commencement of 1893 the representatives of the work-people assembled in force. There were two vacancies on the committee, the Rev. Canon Gregory and the Rev. H. Bonnor being ineligible for re-election because they had attended the fewest number of meetings since the last election. As a result two workmen representatives were elected in their stead. Speaking of the General Dispensary annual meeting of 1894, *Forward*, a small paper which serves as the organ of the Hospital Saturday Fund, says: "The summary of receipts and expenditure shows another fact worthy of notice. For the first time for many years past the receipts from subscriptions, interest on funded property, and donations, have been expended on the general work of the institution. That is to say, that for the first time we believe since the Hospital Saturday Fund has been in existence the donation from it has been applied to the purpose for which it was given. So long as there is scope for additional work in the town we do not think any institution has a right to save money out of its ordinary income. Whether the alteration in the policy of the dispensary is to be attributed to the working-men representatives on the committee or not we cannot say; but whatever the cause may be, the dispensary is to be congratulated on the wise policy which has been pursued during the year."

This passage meets an objection made to me by some of the former medical officers of the General Dispensary. They complained that the dispensary made profits out of the subscriptions, which they employed to build branches at great cost, provided even with bedrooms in the upper part of the building. The fact that the workmen had obtained a strong representation on the committee of the General Dispensary naturally gave rise to many objections, particularly when it was found that the workmen were very regular in their attendance, and, by showing greater devotion to the business at hand, soon obtained a preponderating influence. The fact that they came in an organised body and carried the election caused them to be described as "daylight robbers." They were accused of initiating a "subtle predatory policy," and the gentlemen who gave guineas instead of pennies were warned that they must follow similar tactics to save the charities from being misappropriated by the working classes. Nevertheless, and in spite of the fact that the workmen are now in a majority on the committee, the subscriptions have not fallen off, there is no complaint as to mismanagement, and the average attendance at committee or business meetings has never been so regular and numerous. But all this, however favourable it may be from one point of view, does not meet the question of abuse. It is still the opinion of a great number of general practitioners and others that an enormous amount of abuse prevails at the General Dispensary. It has become less and less a charity, more and more a provident dispensary. Mr. Smelley, the principal organiser of the Hospital Saturday Fund, expressed the opinion that what abuse exists arises out of the patronage of subscribers, who are apt indiscriminately to give away tickets. But, he added, the workmen are interested in preventing abuse, and he invited any medical man connected with the dispensary to signalise any case of abuse, guaranteeing that the name of the person in question would at once be struck off the books.

This, however, is not so easy to do. In the absence of systematic inquiry, the fact that the patient is able to pay proper medical fees is generally only ascertained after he has obtained medical relief. The medical officers also are too busy to make inquiries; this constitutes no part of their work, and it is only accidentally that they discover a few of the many cases of abuse. It is undoubtedly more pleasant to attend a better class of patients and to visit the sick who live in houses that are fairly clean and well kept. Also, many general practitioners now established in Birmingham have commenced their careers as medical officers of the dispensary, and they would not have acquired their present popularity if they had made enemies by inquisitorial proceedings against their dispensary patients. A young practitioner who is seeking to acquire a reputation naturally prefers that his skill should be appreciated by well-to-do people. It is not very probable, therefore, that when he has the good fortune to meet with a better class patient he will at once take measures to have his name struck off the books. In such a case the interests of the present and of the individual clash with those of the future and of the profession. It is only when the young practitioner leaves the dispensary and suffers from the deeds of his successors that he fully realises how his own conduct was lacking in foresight.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Druggists' Prescriptions.

AT a recent meeting of the Health Committee a report was read on a number of samples of medicine prepared from prescriptions by druggists in different parts of the town. In twenty-four instances irregularities were found, but these appeared to be due more to careless or unskilful dispensing than to intention to defraud. For example, in one case the principal drug, though far more expensive than the other items of the prescription, was found to be the one in excess. This, the report pointed out, was a matter of at least as great importance as was the protection of the customer from fraud, as the action of a medicine often depends upon the care with which the proportion of the various drugs mentioned in the prescription is dispensed. After consideration the committee ordered that a prosecution should take place in one case, and that in about a dozen others the druggists should receive a written caution.

Death under an Anæsthetic.

A sad fatality lately occurred in the rooms of a dentist, when a man, aged twenty-seven years, met his death on the administration of A.C.E. mixture taken for the extraction of teeth. There was evidence to show that it was skilfully given by a medical man.

Boxing Contests.

In the recent case of the young man who lost his life at a boxing contest held at the Olympic Club the grand jury at the assizes found no true bill. The case was therefore thrown out. Still, many are of opinion that such contests are brutal and degrading. Some belief exists that the law is sufficient to prohibit such exhibitions, and that in the interests of humanity and social order they should be stopped.

Foul Air in Sewers.

The above subject forms matter of complaint in the local press. A veteran Fellow of the Royal College of Surgeons leads the charge and formulates grave accusations against the system which admits of the escape of foul air from the sewers into the streets and houses. Much is to be said on the subject, which in the future must command the attention of the authorities, though involving great outlay and much consideration.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Port Sanitary Authority.

DR. F. W. BARRY, one of the inspectors of the Local Government Board, held a formal inquiry at the Manchester Town-hall on the 28th ult., with regard to the regulations

Digitized by Google

laid down under the General Order of the Local Government Board, issued in November last, as to the treatment of persons affected with cholera, yellow fever, or plague, and the prevention of the spread of these diseases in the ports of Liverpool and Manchester. The inspector said the inquiry was really held in order that they might carry out the arrangements made by one of the earlier conferences of the authorities to regulate the dealing with vessels on which there were cases of cholera. Since then the Quarantine Act had been abolished, and they had now to deal also with yellow fever and plague. It was thought that it would be most convenient if Liverpool dealt with such cases, and a draft order had been made giving this power to Liverpool, the cost to be charged on the Manchester Port Sanitary Authority.

Manchester Hospital Sunday and Saturday Fund.

At a meeting of the committee of this Fund the following statement respecting the collections for 1897 was submitted: Balance from last year, £264 15*s.* 2*d.*; collections, 1897—Hospital Sunday, £3959 10*s.* 8*d.*; Hospital Saturday, £4102 19*s.*; bank interest, £21 12*s.* 2*d.*; total, £8348 17*s.*; less expenses, £668 1*s.*; amount available, £7680 16*s.* Of this sum it was resolved to distribute £7500 amongst the medical charities.

Salford Sewage Scheme.

It seems as if at length there were some prospect of an end being put to the hesitation shown by Salford as to the treatment of her sewage. On the 22nd ult., at the Salford County Court, Judge Parry heard the adjourned application of the Mersey and Irwell Joint Committee for a peremptory order to compel the Salford Corporation to carry out a scheme ordered by the Local Government Board for dealing with the effluent from the Salford sewage filtration works. This involved the provision of at least 100 acres in addition to the land already acquired for dealing with the effluent from the filtration works. But the corporation have at length decided on a scheme, and rebel against that of the Local Government Board—not so audacious a proceeding, however, as it at first appears—for a recent deputation to the Board succeeded in showing that it would be impracticable to carry out the scheme ordered, and that Salford could do something better. Certain alterations are to be made in the existing precipitation tanks, and the appliances for sludge removal re-constructed. Two of the twelve precipitation tanks are to be converted into roughing filters. There is to be an area of 24,000 square yards for aerating or bacterial filters, with supply pipes, valves, effluent culverts, &c.; also buildings and machinery for preparing the cinders, &c., for the filters, and for cleansing and renewing the material as required. The engineer, Mr. Corbett, said his plan provided ten acre filter beds, but they proposed to deal with five first, and if necessary with the remaining five afterwards. The resolution of the council provided for the expenditure of £80,000 for doubling the filtration area. His Honour said there would be an extension of time for two years, and it would be for the corporation to give the joint committee particulars from time to time of what they were doing, and if the corporation could not carry out this there would be no alternative, so far as he was concerned, but to put the penalties into force. But even now the scheme is to be opposed, for Salford often takes one step forward and another back.

The Sanitary Committee of the Corporation.

The report of the above committee for the year ending April 30th last shows that an immense amount of work has been done; 45,119 complaints of nuisances were made and attended to; 76,599 inspections were made by the twenty-eight district inspectors and four smoke inspectors. It is stated that there are 2499 registered dairies, cow-sheds, and milk-shops; that 4237 inspections of these were made; and that 1472 cows are kept within the city. During the year 2813 cases of infectious disease were reported to the medical officer of health. It seems that there are 472 bakehouses on the register, respecting which 360 defects—chiefly want of cleansing and lime-washing — were reported. Of 1587 articles of food and drugs procured for analysis 49 were adulterated; 1068 insanitary houses were dealt with by the Unhealthy Dwellings Sub-Committee. The details of the report show considerable and much-needed activity on the part of the committee.

Aug. 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Sale of Carbolic Acid.

THE facility with which carbolic acid can be purchased by the public was the subject of unfavourable comment by the city coroner in a case of suicide from the effects of that drug investigated by him on the 7th inst. The coroner remarked that it was a lamentable fact that carbolic acid could be purchased as easily as milk, that the legislature had done nothing to restrict the sale of the poison, and it was a great pity that nothing was apparently being done in that direction. The jury concurred in the coroner's strictures, and hoped that greater restrictions would be placed on the sale of carbolic acid to the general public.

Munificence of the David Lewis Trustees.

The David Lewis trustees have intimated to the committee of the Liverpool Nurses' Home their desire to build a central building, to be the central home and office for the district nursing of the city, if the committee will submit a scheme which meets with the approval of the trustees. This will place the Jubilee Commemoration Scheme in a very satisfactory position to make Liverpool a model in the matter of nursing the poor in their own homes. It ensures the erection of a suitable central home, considered necessary as an administrative centre of the newly-organised body; and also expresses in a permanent form the share of Liverpool in commemorating the sixtieth anniversary of the Queen's reign. But when the city is thus organised the new scheme will still require enlarged support, both in subscriptions and in the number of lady superintendents and other workers. A committee of the Jubilee Commemoration Fund was appointed to confer with the committee of the Nurses' Institution in regard to the arrangement of the scheme.

The Bidston Hill Purchase.

Bidston Hill has long been a favourite resort for Liverpool and Birkenhead excursionists. Situated about two miles to the north of Birkenhead and three or four miles distant from Liverpool, it is consequently within easy access of those towns. It contains on its summit—from which charming views of parts of Lancashire, Cheshire, and North Wales can be seen—the Liverpool Observatory, the property of the Liverpool Corporation, close by which are the famous rhododendron gardens, attracting during the season thousands of visitors. The walks on the heathery slopes around the hill, with pleasing views, all combine to make Bidston Hill a most attractive place. It cannot be wondered at, when it was in danger of falling into the hands of the builders, that great efforts were made by both Birkenhead and Liverpool to preserve this healthy lung in its present invigorating condition. Subscriptions were appealed for, and it is satisfactory to record that by the help of a pecuniary grant from the Corporation of Birkenhead the requisite sum of £18,500 has been raised; this amount has enabled the committee appointed for the purpose to purchase about sixty-two acres, and practically the whole of Bidston Hill has been secured for the benefit of Birkenhead and Liverpool. It is in contemplation to lay out the grounds in gardens and to make the hill generally attractive if it be possible to improve its present surroundings. The Corporation of Birkenhead deserve praise for the ready and liberal manner in which they performed their part of this useful and health-giving scheme. As an elevated marine parade in the immediate vicinity of a large and increasing population Bidston Hill has but few rivals; and it is a matter for thankfulness that this salubrious property has thus been purchased, and by these means snatched from the hands of the Philistines.

The New Medical Superintendent of the Mill-road Infirmary.

There were fifty-eight applicants for the vacancy at the Mill-road Infirmary, which is a valuable appointment. Eventually the choice of the guardians rested on Dr. Nathan Raw, who had filled responsible posts at the Borough Lunatic Asylum, Portsmouth; at the Kent County Asylum; and latterly at Dundee. Dr. Raw received his medical education at Newcastle-on-Tyne, and is a graduate in medicine and surgery of Durham University.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Graduation Ceremonies.

THE summer graduation ceremonial in the Edinburgh University was held on Saturday last. The Principal, Sir William Muir, presided. An unusually large number of gentlemen received the degree of M.D. The ceremonial was held in the Synod Hall, as the MacEwan Hall was not quite ready, and was, as is usual, witnessed by a large gathering of the public. Gold medals were awarded to the following for their theses: Dr. Friedrich Wilhelm Eurich, Dr. William Edward Fothergill, Dr. T. A. Wemyss Fulton, and Dr. David Arthur Welsh. The Ettles Scholarship was awarded to Mr. Edwin Matthew, M.B. The graduates were addressed by Professor Cossar Ewart. He referred to the medicine of the ancients and to their ideas of the causation of disease. Coming down to more recent times, he referred to the more important generalisations that had placed medicine and surgery upon their present footing.

Public Slaughter-house for Aberdeen.

A special committee of the town council have reported that in their opinion the time has come for the corporation to erect a public slaughter-house. They recommend the construction of an abattoir at a cost of £30,000, but name no particular site. The committee's report was approved, and the committee were instructed to report as to the best site to be obtained as well as to other particulars.

Aug. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Epidemic of Beri-beri at the Richmond Asylum, Dublin.

A SPECIAL meeting of the governors of the Richmond Asylum was held in the board-room of the asylum on Aug. 3rd. The meeting was called by the resident medical superintendent, Mr. Conolly Norman, for the purpose of providing some remedy to prevent the further spread of disease in the institution. In his report Mr. Conolly Norman stated that 150 persons in the asylum had been attacked with beri-beri during the last two months, that this was the third year in which this epidemic had appeared, and that the disease had not been absent since last summer—the summer of 1896. He stated, moreover, his opinion that the Richmond grounds were now unsuitable for any building, and suggested that Grangegorman Female Prison should be obtained if possible, in order that a considerable number of his patients might be removed so as to allow the old buildings to be thoroughly aired and disinfected. After a long discussion a resolution, proposed by Mr. B. R. Balfour, J.P., including a memorial to his Excellency the Lord Lieutenant of Ireland for the temporary use of Grangegorman Prison, was unanimously passed, and his Excellency consented to receive the deputation upon Aug. 10th. There are now (Aug. 10th) 172 cases of this disease at the Richmond Asylum, Dublin, consisting of 125 female patients, 42 male patients, 3 nurses, and 2 attendants. The number attacked in this outbreak is therefore nearly as high as in the epidemic of 1894. Since the disease first appeared at the Asylum no less than 459 cases have been under treatment.

The Royal Victoria Eye and Ear Hospital, Dublin.

Her Majesty the Queen has been graciously pleased to direct that the institution recently formed under the Act of Parliament which amalgamated St. Mark's Ophthalmic Hospital, Lincoln-place, and the National Eye and Ear Infirmary, Molesworth-street, shall be called the Royal Victoria Eye and Ear Hospital, Dublin.

The Belfast Water-supply.

Dr. Percy F. Frankland, of Mason College, Birmingham, has, at the request of the Belfast Water Commissioners, made a careful analysis and examination of their water-supply and filter beds, and has issued a very full report with the following conclusions: (1) He believes that from the nature of the gathering grounds the water-supply of Belfast is liable to contain a very large proportion of organic matter; and hence (2) he recommends that it be submitted to prolonged storage and very careful filtration; (3) he considers that Belfast has a most admirable series of filter-beds, constructed on the most approved principles and worked with great care and attention; and (4) he believes from his examination that the filtration is highly efficient in the removal of organic matter and in the removal of micro-organisms. He recommends, to make the filtration complete—(1) running to waste as much of the filtrate as can be spared after each cleaning; (2) uniformity in rate of filtration employed; (3) the employment of the lowest practicable rate of filtration; and (4) the use of the finest sand procurable.

Health of Belfast.

From the report presented by the public officer of health at the quarterly meeting of the City Corporation, held on Aug. 2nd, it is satisfactory to know that the health of Belfast is in a more satisfactory condition than it has been for many years. The death-rate is lower than it has been for a long time past, 17 per 1000, calculated on the population of the city as 300,000. The cases of zymotic disease reported during the month—more especially typhoid fever—have largely decreased, and the deaths are much less numerous. There are still a good many deaths from whooping-cough in spite of the warm weather, while the epidemics of scarlet fever and measles have almost died out.

The Legal Privileges of Druggists.

At an inquest held in Belfast on July 27th in reference to a man who had committed suicide by cutting his throat with a razor, a curious question of privilege was raised in reference to a druggist who was alleged to have prescribed for the deceased some time prior to his death. The coroner having asked the druggist if he had his books containing the prescriptions he had made up for the deceased, that gentleman said these books were his private property containing thousands of prescriptions for individuals throughout the city, and he had been advised not to produce them till he was compelled by a superior court. A solicitor who appeared for the druggist said it would be a most disastrous condition to place a druggist in to make him come into court with books containing the names of different individuals and the prescriptions made up for them as recommended by the several medical gentlemen throughout the city of Belfast. It would be the same as to drag a medical man into the witness-box and ask him with regard to all the patients he had attended during the twelve months the particulars of their complaints and the articles he had given them. He cited the well-known London medical case, so fresh in the recollection of the profession, and said druggists would suffer in their practice if they divulged their prescriptions. No one seeking a prescription would go to a druggist at all if prescriptions were to be placed before a jury showing the ailments in connexion with every family and every individual. Therefore, in the interests of the profession of druggists, he would not advise his client's books being produced unless they were brought forward by the direction of a competent court. The coroner said it was only wanted that the druggist should produce whatever book contained an entry of a prescription in regard to the individual in whose case they were holding an inquest, and as the druggist swore there was no entry in his books in regard to the deceased this question lapsed; but the very interesting point still remains—can druggists be compelled in a court of law to produce the books containing the copies of the prescriptions given them to be made up by customers? It is a point which I do not remember to have come up before, and of course this Belfast case does not by any means settle the matter. In the hearing of the case it came out in evidence that a bottle had been found with the deceased man with a druggist's label upon it, and it was sworn that three years before his death a person went with the deceased to the druggist, who examined (sounded) him and prescribed for him. The coroner, in summing up, said it was of the utmost importance to the public that those to whom they went for medical advice or surgical treatment should be men qualified to give that advice or treatment. It would also place the medical profession in an unfair position. Now it was notorious in Belfast that persons without qualification were extensively doing the work of medical men daily. There were, he was sure, a hundred young struggling men in the medical profession at Belfast, and he thought the men at the head of their medical societies, whose positions as physicians and surgeons were now assured, should look to the protection of the interests of their young brethren, which meant the protection of the interests of the public. He ventured to hope that the Pharmaceutical Society would,

Digitized by Google

not only in the interests of the honourable members of their society, but in the public interests, endeavour to put a stop to the practice of prescribing by druggists. The jury found that the man had committed suicide while temporarily insane and that there was not sufficient evidence to show that the druggist had made up any prescription for him.

Presentation to Mr. Fagan, F.R.C.S. Irel.

Mr. Fagan, who is leaving Belfast for Dublin (having been appointed to an official position), has been the recipient of a handsome gift from the members of the medical profession in Ulster. The presentation, which consisted of a quantity of silver plate, was made to Mr. Fagan on July 30th at his country residence, Little Clandebrye, co. Down, on the occasion of a garden-party given by him and Mrs. Fagan to celebrate their silver wedding. A very large number of friends, including members of the medical profession of Belfast and surrounding districts, were present, and, in conveying the presentation, Dr. Walton Browne (senior surgeon to the Royal Hospital, Belfast) expressed the regret felt by the members of the medical profession at the departure of Mr. Fagan and his popular wife from Belfast. In his feeling reply Mr. Fagan alluded to the cordial relations which had always existed between himself and his professional brethren.

North of Ireland Branch of the British Medical Association.

At the annual meeting of this branch, held on July 29th, Dr. Gray (Armagh) was elected president for the ensuing year. Communications on medical subjects were brought forward by Dr. Hall (Monaghan), Dr. Darling (Lurgan), Dr. Calwell, Dr. St. Clair Boyd, Dr. Colville, and Dr. Donnan (Holywood). The annual dinner took place on the same evening, when Professor Whittle (the outgoing president) occupied the chair, and Mr. Fagan, who was the guest of the members, was presented with an address on the occasion of his leaving Belfast.

The Newry Workhouse.

The decision of the Local Government Board in reference to the recent sworn inquiry held by one of their inspectors into the general management of the Newry Workhouse indicates what indeed must be described as a most scandalous state of affairs. The Local Government Board, upon a review of all the facts elicited at the inquiry, have no hesitation in condemning the whole management of the workhouse. They say the conduct of the master has been such as to prove him unfit for such a responsible position, and they call on him at once to tender his resignation. Two nurses are also called on to resign, and a third one the Board would not have allowed to retain her position had she not resigned herself, and they advise the guardians not to give her the testimonial she applied for, having regard to her manifest neglect of duty. The schoolmistress is also called on to resign, the Board regarding her intriguing conduct as subversive of discipline and as being one of the chief causes of the ill-feeling at present existing in the workhouse. The schoolmaster is warned to observe in future the rules as to classification, and to endeavour to maintain the authority of the person who may be appointed the new master. A special meeting of the Newry board of guardians is called for Aug. 17th to consider this report, which indicates a most lamentable condition of matters as existing in the Newry Workhouse.

The New County Tyrone Infirmary.

It is rumoured that the Duchess of Abercorn, who is to entertain the Duke and Duchess of York at Baronscourt during their coming Irish visit, is using her influence to get her Royal Highness to lay the foundation stone of the new county infirmary at Omagh. It is said that the required money for the new building is being rapidly raised.

The Record Reign Collection in Aid of the Cork Hospitals.

The collection made under the above title has amounted to £3350, and on Aug. 7th was allocated as follows by the Executive Committee:—North Infirmary, £500; South Infirmary, £500; Fever Hospital, £350; Women and Children's Hospital, £400; Mercy Hospital, £300; Protestant Incurable Home, £250; St. Patrick's Hospital for Cancer and Incurables, £250; Eye, Ear, and Throat Hospital, £400; Lying-in Hospital, £300; Queenstown Hospital, £100.

Aug. 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Hernia.

AT the Academy of Medicine M. Lucas Championnière, in answer to the recent communication of Professor Lannelongue upon the treatment of hernia by the sclerogenic method, recently brought to the remembrance of members the present status of the radical operation which he himself considers one of the most remarkable victories of modern surgery. In M. Championnière's opinion no radical cure is possible except by a very extensive operation, and the more complete and thorough the operation is the better are the results. He brought forward a number of statistics in support of his argument. According to him all petty operations or methods of treatment should be avoided. Injections, in particular, are painful, dangerous, and inefficacious. The following is the best way of operating, according to M. Championnière. The opening into the hernial sac must be very free and must extend into the abdominal cavity so that the operator may be able to have as good a view as possible. As much omentum as possible must be excised, together with the whole of the sac and its neck. All thickened peritoneum in the region of the hernia must be removed, and the abdominal wall must be restored as far as possible by making the margins of the incision overlap and not merely joining them edge to edge. In this way the thickness of the wall in the hernial region is doubled. The wound is closed and drained in the usual way. This method of operating brings about an absolutely accurate restoration of the abdominal wall, but nothing except a very complete and accurate operation is of any use. This operation, which M. Championnière has devised after an experience extending over many years, and with which he has had many successful cases, appears to him to be the best one possible.

Cancerous Alteration of Gastric Ulcer.

At the Société Médicale des Hôpitaux M. A. Mathieu has described the occurrence of cancerous changes in gastric ulcers, and has come to the conclusion that it is not very rare. He reports three cases in which the diagnosis of cancer supervening upon ulcer could be made during life, and in which both the post-mortem and the histological examinations confirmed the diagnosis. In the first case it would appear that the beginning of the disease was marked by an excessive secretion of hydrochloric acid accompanied by pain, which commenced twenty-four years before death. Ten years before death unmistakeable signs of simple gastric ulcer appeared, but the diagnosis of cancer was only made after a laparotomy. In the second case the phenomena of simple ulcer appeared ten years before death. The appearance of acanthosis nigricans and enlargement of the left subclavicular glands led to a diagnosis of cancer nearly two years before death. In the third case the simple ulcer preceded the cancer by nearly two years. At the post-mortem examination the cancerous nature of the lesions was evident by the presence of cancerous nodules in the liver or in the mesenteric glands. In every case there were found in the centre of the cancerous lesion traces of the primitive ulcer, and in one case the ulcer was, as far as naked-eye appearances went, of a simple chronic nature, but there were marked epitheliomatous infiltration and thickening of the muscular coats of the stomach.

Professional Secrecy and the Notification of Epidemic Diseases.

An interesting matter bearing upon public health administration has just been threshed out in the Court of Appeal at Rouen. Last year a medical man of Arpajon, in conformity with the regulation of Nov. 30th, 1892, notified to the mayor of that town five cases of diphtheria in children occurring among his patients. Some days later a municipal councillor, under the excuse of wishing to know if the regulations had been complied with, and if, as was commonly reported in the town, some cases of croup had occurred, asked the secretary of the *mairie* to show him the certificates sent in by the medical man, because, he added, he wished to raise a question about the matter at the next meeting of the municipal council. This proceeding took place without the knowledge of the mayor, and the municipal councillor took advantage of it to criticise the diagnosis of the medical man. Upon the complaint of the latter the secretary

Digitized by Google

of the *mairie* was haled before the Correctional Tribunal of Corbeil under the Act for preventing the disclosure of secrets, of which his position made him the legal depositary. It was urged on behalf of the defence that the accused was not bound to secrecy; that he was bound by no oath; that he was only a servant of the mayor; and that medical notifications were not secret, since by the regulation of Nov. 30th, 1892, he had nothing to do with professional secrets. The Tribunal of Corbeil accepted this argument and acquitted him. At the instance of the Procureur of the Republic the affair came before the Cour d'Appel in Paris, where it was further maintained on behalf of the accused that the secretary of the *mairie* could not withhold the documents in question from a municipal councillor who wished to ask a question of the mayor as to what measures he had taken for safeguarding the public health. The Cour d'Appel of Paris, without inquiring whether the secretary of the *mairie* was bound to maintain secrecy, and whether notifications made by medical men in accordance with the law were to be kept secret, accepted this last-mentioned argument, and decided that this servant of the mayor might disclose notifications to a municipal councillor who intended making further investigations on the subject. The Procureur-Général at the Cour d'Appel of Paris appealed against this judgment in the Cour de Cassation, and that tribunal held that the secretary of the *mairie* was the depositary of secrets in his legal capacity, that notifications of epidemic disease were without doubt of a secret nature, that by the regulation of Nov. 30th, 1892, professional secrecy had been made subordinate to the interests of public health, but that both the letter and the spirit of the Act went to show that secrets revealed by a medical man to the authorities under certain definite conditions still remained secret and must not be divulged to any other than the constituted authorities. The Cour de Cassation accordingly reversed the judgment of the Cour d'Appel of Paris, and remitted the case to the Court of Rouen. The Court of Rouen gave effect to the finding of the Cour de Cassation.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Heat and Suicide.

I AM writing "Die Sanctæ Mariæ ad Nives," on the feast of Our Lady of Snow, invoked every 5th of August by many suppliants, but by none more fervently than those who pray for the remission of the great heat, with all its disastrous consequences. Among these latter may be enumerated the appallingly frequent suicides, which have this year risen to an unprecedented figure. In Florence alone from May 2nd to Aug. 2nd the cases of self-destruction were no fewer than forty-four. In other cities the proportion was also above the average, but the Tuscan capital, as it was the most heavily visited by the heat, so it has much the largest tale of suicides to tell. The mode of death mainly courted by these unfortunates is also significant—that by drowning. At other seasons the revolver and asphyxia by charcoal placed under the bed in a hermetically sealed room seem to be preferred. But these methods are naturally not in favour with the thermometer standing at 109° F. More than one-third out of the forty-four suicides in the three months above given destroyed themselves by immersion in the Arno, in those parts of the river between the Porta di San Niccolò and the Cascina, where the water maintains sufficient depth. "Dissesti finanziari" (money difficulties) and "miseria" (homelessness and starvation) are among the chief motives, the victims being often far beyond middle life, having reached sixty, sixty-five, or even seventy years of age. With the departure of the foreign, particularly the English-speaking, world the Italian winter city seems to lose all vitality or energy—no money is in circulation, trade is at a standstill or nearly so, servants, waiters, cooks, domestic hangers-on of every kind, all are "a spasso" (on the pavement), counting the hours till the tourist or travelling season returns and money again begins to engorge the shrivelled currency. The pitiless blue sky, the tropical heat, and the high nerve excitation involved under these conditions seem to supply "miseria" with the force to take the final, fatal plunge, and so nearly every second day we have a "suicidio consumato" (an effective suicide) and almost as often a "suicidio tentato" (an abortive one). Of course there are other motives coincident with "Southern blood" which prompt to self-destruction—"miseria" does not account for all. There is thwarted love among the comparatively young or disappointed ambition among the adults. But "mancanza di quattrini" (impecuniosity) and the hardness of living it implies is responsible for the vast proportion of cases—insomuch that one trembles to think what dimensions suicide would attain in Italy if the £20,000,000 in gold annually poured into her coffers by the English-speaking world were withdrawn or even diminished. Yet, with Italy's dependence on that world for so large a portion (actually one-third) of her revenue, there are to be found Italians—and I am sorry to say, medical Italians—who are agitating the Legislature to scare English-speaking visitors away by insisting that they shall have no professional advice or attendance of their own nationality, but be compelled to call in the native practitioner! Such an enactment would be "suicidal" indeed—a confirmation (by Italy, diplomatic Italy!) of the great Swedish diplomatist's memorable saying to his son:—"I, puer, et disce quantillâ sapientiâ regatur mundus" (Go, boy, and learn with how little wisdom the world is governed.)

A Feat of Memory.

The purely intellectual attribute we call memory, which "is not a function, but only a resultant due to the concurrence of the various elementary functions of the mind," is capable of almost illimitable development, as Max Müller's accounts of the recitations of the Brahmins or Sir William Hamilton's references to the feats of the humanists of the Renaissance sufficiently demonstrate. Both the philologist and the metaphysician, however, are at one in thinking that the habits of the present time—above all the desultory, particularly the ephemeral, reading now well-nigh universal—are not favourable to such feats. Indeed, Max Müller says that the daily perusal of the *Times* for ten years would have sufficed to impair the strongest memory ever Brahmin possessed. That the feats, however, of a Scaliger or a Lipsius are, even at the close of the nineteenth century, quite possible, was demonstrated the other day at Sondrio (capital of the Valtellina) where the advocate Signor Edoë, professor in the Istituto di San Lorenzo, repeated, for a wager, in twenty hours consecutively—from 6 P.M. till 2 P.M. of the next day—without prompting or aid of any sort, the entire Divina Commedia of Dante. The achievement came off in presence of a committee of brother professors and literary men, who afterwards entertained the performer at a banquet, not unwelcome, one would imagine, to either party after such an effort of brain-tension and vocal articulation on the one hand, and sustained surveillance *ad aperturam libri* on the other. The Divina Commedia, I need hardly remind the reader, consists of nearly a hundred cantos, and of all poetical compositions is the least diffuse—characterised, that is to say, by the closest condensation of thought and expression. The late Duke of Sermoneta (Sir Walter Scott's *fidus Achates* on his memorable visit to Rome in 1832) could also repeat the Divina Commedia from first to last, but that was the result of life-long study, not, as in Signor Edoë's case, the outcome of comparatively short preparation, begun and ended for the purpose of winning a wager.

(FROM OUR OWN CORRESPONDENT.)

The Operative Treatment of Myopia.

A PAMPHLET on the operative treatment of myopia, which has just been published by Dr. Fukala, has attracted considerable attention in medical circles in Austria. It contains an interesting account of the stages by which the author was led to remove the lens in cases of high myopia, in spite of the fact that the operation was not approved of by ophthalmologists so distinguished as Donders, Graefe, and Arlt. In many cases he has found that the patient's distant vision was good after the operation and that near vision was also improved. Choroiditis is not a contra-indication. The lens is divided into several portions by Graefe's small knife; after some days when there are symptoms of cyclitis and increased tension linear extraction is performed without excision of the iris. Many eminent German

Digitized by Google

ophthalmic surgeons have operated in this way and have obtained brilliant results. After the removal of the lens there is a great decrease of the refraction, varying in amount from 15 D. to 16 D., and in one case even reaching 28 D. The detachment of the retina which accompanies high myopia is also checked. Dr. Fukala has succeeded in proving that high myopia is caused, not merely by the lengthening of the axis of the eye, but also by an increase in the refracting power of the lens. Professor Vossius has shown his appreciation of Dr. Fukala's operation by comparing it to the operation for iridectomy devised by Professor Graefe.

Statistics of Anæsthesia.

The Surgical Society has published in the *Journal für Zahnheilkunde* further statistical returns on the subject of anæsthetics, which have been collected by Dr. Gurlt. The administrations reported are 58,769 in number, including 27,000 of chloroform, with 29 deaths; about 19,000 of ether, with 3 deaths; 5000 of Billroth's mixture (morphia chloroform and alcohol), without a death; 996 of bromide of ethyl, without a death; and 5890 of chloroform and ether, without a death. During the last two years 32 deaths have been reported, being 1 death in 1836 administrations. Altogether, 327,953 administrations, with 134 deaths, have been reported since the year 1891, being a proportion of 1 in 2444. Arranged according to the resulting mortality the various anæsthetics appear as follows: Pental, 1 death in 213 administrations; chloroform, 1 in 2039; Billroth's mixture, 1 in 3897; ether, 1 in 5019; bromide of ethyl, 1 in 5228; chloroform and ether, 1 in 7594. The mortality from chloroform has increased from the year 1891 to the year 1897, the figures being as follows: In 1891, 1 death in 2700 administrations; in 1892, 1 in 2300; in 1893, 1 in 4200; in 1894, 1 in 1900; in 1895, 1 in 1300; in 1896, 1 in 1400; and in 1897, 1 in 1126. The mortality due to ether was 1 in 5600 administrations during the first three years, 1 in 3100 during 1895, 1 in 2600 during 1896, and 1 in 6700 during 1897.

The Primary Symptoms of Congenital Syphilis.

At a recent meeting of the Vienna Medical Club Dr. Hochsinger, describing his theory of congenital syphilis, said that the primary symptoms in the fœtus and the young infant show a special tendency to diffuse infiltrations, whereas in the primary forms of acquired syphilis and the secondary forms of hereditary syphilis limited cell proliferations were more common. These diffuse infiltrations are well seen in the visceral affections due to congenital primary syphilis, and developed during the intra-uterine life of the fœtus; localised manifestations are rare, and when they occur may even be ascribed to congenital tuberculosis; for, according to Baumgarten's researches, there is a connexion between congenital tuberculosis and congenital syphilis. Another consequence of hereditary primary syphilis is that changes analogous to those in the viscera of the fœtus occur in the cutaneous tissues of the young infant, the special symptom being a diffuse infiltration of the skin of the palm of the hand and the sole of the foot. Histological examination shows in both the visceral and the cutaneous processes an inflammatory cell proliferation originating in the tunica adventitia and the perivascular tissue of the small arteries. In the skin the primary seat of the affection is in the sudoriparous glands, the arteries of which, as well as the veins and capillaries, show very marked cell proliferation. The fact that the inflammatory process in its first stage is limited to the vessels implies that the virus circulating in the blood irritates the coats of the vessels. Diffuse syphilitic inflammation first manifests itself in the intestinal glands of the fœtus, and it may be said that there is no syphilitic fœtus whose liver is not the seat of a similar process affecting the vessels and the connective tissue; as a rule, this condition occurs also in the kidneys, the lungs, and the pancreas. Eruptions on the skin, on the other hand, are peculiar to extra-uterine life. The explanation of these phenomena must be sought for in embryology. The parenchymata of the visceral glands are formed in the second, third, and fourth months of intra-uterine life, the glandular elements of the skin in the fifth month, and the first vascular lumina in the sudoriparous glands in the seventh month; it is therefore obvious that until the glands of the skin are developed it cannot have the vascular system and the copious blood-supply possessed by the visceral glands at a much earlier date. The palm of the hand and the sole of the foot are exceptions to this rule, for they are abundantly furnished with sudoriparous glands, and are by this anatomical peculiarity rendered liable to congenital eruptions such as congenital syphilitic pemphigus.

Vienna University.

The honourable distinction of Rector of the University of Vienna for the year 1897–98 has been conferred on Professor Toldt, a member of the medical faculty. Professor Toldt is a very able anatomist who has made important investigations on the development of the peritoneum, and has published numerous memoirs on embryological subjects. His most important works are his "Lehrbuch der Descriptiven Anatomie des Menschen" (Manual of Descriptive Human Anatomy) and his "Anatomischer Atlas," which is beautifully illustrated and is expected to be completed very shortly. Dr. Victor Ebner, the eminent professor of histology, has been elected Dean of the Medical Faculty. Some years ago he published researches on the histology of the tubuli seminiferi, in which he explained the origin of the spermatozoa. Two kinds of cells are concerned in the process, Sertoli's cells and the spermatogonia. By division each spermatogonium gives rise to six or eight spermatoids, the nucleus of each of which becomes the head, and the protoplasm the tail, of a spermatozoon. Each spermatozoon enters into combination with a Sertoli's cell, and both form Ebner's spermatoblast.

Aug. 1st.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Congress in Moscow: Excursions to the Caucasus.

SOME details of the excursion to the Caucasus, which has been arranged for members of the International Medical Congress, have already appeared in THE LANCET.[1] The following additional details have now been published by the executive committee. As already stated in the former notice of this excursion the party will divide into two after visiting the mineral waters of the Caucasus; one-half going by the Georgian Military Road to Tiflis, and the other proceeding to Petrofsk, on the Caspian Sea, when they will take steamer to Baku, and thence will travel by rail to Tiflis, where they will join the first half. From Tiflis the re-united party will take the train to Batoum on the Black Sea, breaking the journey at Borjom, where are some mineral springs of considerable repute. From Batoum there will again be a choice of routes: it will be open for the traveller to go direct by steamer to Novorossiisk and Rostof-on-Don, and so by train back to Moscow, or to lengthen the journey by crossing the Black Sea to Sevastopol, where he will have an opportunity of seeing something of the Crimea before returning to Moscow. As a result of this division of the excursionists to the Caucasus into two parties upon two occasions, it follows that there will be four different routes and four different sets of tickets, ranging in price according to the route chosen. The most expensive will cost rather less than £8 first-class and about £5 second-class; while the least expensive will cost about £5 first-class and about £3 second-class. In all, however, there will be some extras to pay; the steamers on the Black Sea and the diligences on the Georgian Military Road not being included in the above prices.

Excursions to the Volga.

Several other trips have been arranged in connexion with the Congress. Two of these will be to the Volga. The first, and shorter, will run from Moscow to Nijni Novgorod; from here the passengers will be taken by steamer down the river to Tsaritsyn, and thence will return by train to Moscow. The second allows of a much longer river voyage. By this route passengers will, after visiting Nijni Novgorod, journey down the whole length of the River Volga to Astrakhan, where it falls into the Caspian Sea; they will then cross the north-west corner of the Caspian Sea to Petrofsk, and from here proceed overland to Kislovodsk, the centre of the Caucasian mineral spa. After inspecting the watering-places they will return by train to Moscow. The cost of these two excursions will be as follows: by the first route, about £6 first-class and £3 5*s.* second-class; by the second route, £7 10*s.* first-class and £5 second-class.

[1] THE LANCET, April 3rd, 1897.

Digitized by Google

Excursion to the Crimea.

Another short excursion is the following. By train from Moscow to Theodosia, in the Crimea; after visiting places of interest in the Crimea, by sea to Odessa; thence by train to Kief and Moscow. The tickets by this route will cost only £4 5s. first-class and £2 10s. second-class. As this tour includes a visit to the Crimea, and also to Kief (the oldest and one of the most interesting towns in Russia), it will probably be taken advantage of by many.

Numbers Attending the Congress.

It is probable that by this time most Englishmen who have applied for tickets for the Congress will have received them. Some little disquietude has been expressed at the delay in distributing them. Such delay seems to be characteristic of international gatherings, and in the present instance the clerical work has been increased by the distribution of the free railway tickets in addition to the members' tickets. The number of members of the approaching Congress seems likely to be little, if any, smaller than the number attending its predecessors. A week ago the following figures were published: Number of members already inscribed, 5000 (approximately), including—Russians, 2400; Germans, 800; Austro-Hungarians, 600; French, 500; Englishmen and Italians, each about 250; and of remaining nationalities about 100.

July 28th (Aug. 8th).

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Diphtheria in Victoria.

DIPHTHERIA is very prevalent throughout the colony of Victoria, and more particularly in the metropolitan district. For the fortnight ending June 12th, 162 cases and 20 deaths were reported, of which 96 cases and 12 deaths were in the metropolis. During the fortnight ending June 24th the number of cases reported was 186, 8 of which were fatal. The metropolis supplied 105 of the number with 3 deaths. In Hawthorn, one of the suburbs of Melbourne, the disease has assumed epidemic proportions and the board of health has made a special investigation of the sanitary condition of the district. The majority of the cases of diphtheria were found to be localised in close proximity to three separate "tips," all of which were in a more or less insanitary condition, consisting of thousands of loads of household garbage quite uncovered. An old open disused drain was found to be a trap for the collection of sewage, and the dairies in the town were, for the most part, in a filthy condition. The State schools were found to be dirty and badly ventilated. Where the disease occurred in a household no proper isolation or disinfection was carried out. The health committee of the local council has been roused into activity, and has recommended that the "tips" be abolished and an incinerator purchased, and that the Health Act be amended so as to give councils the power of prohibiting dairies in the city bounds. The council took exception to the report of the board of health as to the condition of the dairies in Hawthorn, and decided to make a personal inspection in company with the board's inspector.

A Medical Man in Partnership with a Quack: Both Prosecuted for Manslaughter.

A case of some interest to the profession has just been concluded in the Melbourne Criminal Court before Mr. Justice Hodges and a jury. Joseph Alfred Davis and Sydney Walter Spark were charged with manslaughter. Davis is a quack who calls himself a "professor" and a "cancer curer." He has only recently been discharged from gaol, after serving a sentence for manslaughter for his unskilful treatment of a case of cancer of the stomach. Spark is a registered medical practitioner whose qualifications are L.S.A. Lond., 1874, L.R.C.P. and S. Edin., 1875. Davis attended a Mrs. Steel, who had a cancer of the breast, which he undertook to cure for the sum of £20—"no cure no pay." He, however, received £10 cash at the outset and other sums subsequently. His *modus operandi* was the same as that employed by him on previous occasions—the application of a plaster to the affected part, which is left on for six weeks. The tissues under it then become mummified and separate from the living by a line of ulceration, to which a simple resin ointment is applied. In this case, after he had made his bargain, he brought Spark with him when he applied the plaster and on his subsequent visits, and Spark in his evidence said that he was in partnership with Davis. Mrs. Steel became very ill and died. Spark gave a certificate that she died from cancer and asthma. An inquest was held and the post-mortem examination showed that the mode of death was by congestion of the lungs and heart failure, probably secondary to blood-poisoning, as the breast and tissues round it were suppurating. An analysis of the mummified skin over the breasts showed the presence of arsenic in the tissues. Spark, in his evidence, said that the plaster applied by Davis was composed of black sulphur, and that arsenic might be present as an impurity. The medical expert witnesses for the Crown were of opinion that the patient might have lived for twelve months or more if untreated, and that her death was due to unskilful treatment by the accused, removal of cancer by escharotics being an unscientific, dangerous, and obsolete method. The defence put in Quain's "Dictionary of Medicine" to show that escharotics were used by medical men, and that their application in such cases was quite proper, and they called a homœopathic physician, who saw the patient just before her death, who maintained that she died from spasmodic asthma, and that arsenic was a proper application to make to such a cancer. The jury acquitted both the accused.

Lunacy in Victoria.

The Inspector-General of Lunatic Asylums for Victoria, in his report for the year 1896 just presented to Parliament, states that during the year 61 additional persons were registered as insane. The actual asylum population however was only increased by 12, as the patients who had been taken out on trial by their friends and those boarded out were 44 in excess of the number for the corresponding period of the preceding year. The daily average of patients resident was 3970, showing an increase of 41 provided for throughout the year. The number of persons admitted during the year was 683, or 33 in excess of the admissions for the previous year. The re-admissions numbered 123. At the end of 1896 the proportion of insane to sane in the population was 1 to every 279, the figures for the preceding year being 1 to every 285. The difference is not due to an increase in insanity, but to loss of population by nearly 7000. In the opinion of the Inspector-General the condition of the asylums has been steadily improving for ten years, but as at present organised they do not give the patients all the advantages that it should be possible to provide for them. He recommends that the patients should be more classified than at present. Epileptics should be segregated and placed in the Ballarat Asylum, and the space gained in the metropolitan asylums devoted to curable cases. All new cases should be sent to Kew, and two wards there fitted up for the treatment of curable cases. Part of the room gained by removing the epileptics should be devoted to paying patients and should be more comfortably furnished and arranged. Criminal patients should be accommodated at the Ararat gaol or at Pentridge gaol.

Ectopic Gestation Twice in the Same Patient within Seven Months.

The June number of the *Australasian Medical Gazette* contains a paper by Dr. Ralph Worrall under the above heading. The patient, a multipara, was admitted to the Sydney Hospital blanched and anxious-looking, with distended and tender abdomen. She had missed a period and thought herself pregnant. She fell five days before admission and had pain in the right inguinal region. Abdominal section was performed, and many pints of dark fluid blood were evacuated. On the posterior surface of the right broad ligament was a ragged opening. The ovarian artery was tied on each side of the tear, and the ragged portion of the ligament cut out and sutured. The patient made an easy recovery. This was in January, 1896. On Aug. 20th she was seen again. She had again missed a period, and the following day was attacked with pain and slight collapse. She remained in bed, and had two further attacks of pain. She was admitted to the Sydney Hospital, and abdominal section was performed, when a large quantity of dark fluid and clotted blood escaped. The bleeding came from the left tube, which was unruptured, but dilated, and held entangled in its fimbriæ a tubal mole. The patient made an uneventful recovery. Dr. Worrall can find only two cases recorded of

Digitized by Google

repeated ectopic gestation in the same patient, and both of these occurred after the lapse of several years.

Jubilee Honour to the Profession in Australia.

The knighthood conferred on Mr. J. N. FitzGerald, the well-known Melbourne surgeon, has given great gratification to the profession throughout Australia, and certainly was never better deserved.

June 30th.

Obituary.

FRANCIS HENRY BLISS, M.A., M.B., B.C. CANTAB.

MANY Cambridge and St. Mary's Hospital men will be grieved to hear of the untimely death from hæmoptysis, at the early age of twenty-nine years of Francis Henry Bliss. He was educated at Marlborough College and then proceeded to Sidney-Sussex College, Cambridge, where he took his M.A. degree, and subsequently commenced his medical studies, going afterwards to London to St. Mary's Hospital to complete them. He was characterised throughout his student days by great personal charm and refinement of character, which made him a host of friends, by whom their loss is deeply felt. After qualifying in 1893 he was appointed house surgeon to the Royal Portsmouth Hospital. He then went into practice at Edenbridge, in Kent, and was rapidly building up a large practice, and, as usual, making many friends, when last autumn signs of tuberculous disease of the lungs presented themselves. Acting on medical advice he relinquished practice and spent the winter in Switzerland and Italy. His health had greatly improved, and he was on a visit to friends in England when he was attacked with severe hæmoptysis, which recurred and proved fatal on July 28th. Dr. Bliss was the son of Sir Henry Bliss, of the Indian Civil Service, who had only a short time before lost another son, from typhoid fever while serving in the famous Chitral campaign. Dr. Bliss was buried in Oxted churchyard on July 31st, a number of his fellow students and teachers attending to show their respect to his memory. Much sympathy is felt with his widow and little daughter and with his father in this abrupt close of a promising career and in the loss of a man who inspired all whom he met with both esteem and affection.

PROFESSOR VICTOR MEYER.

BY the death of Professor Victor Meyer at Heidelberg on the 8th inst. chemical science has lost an illustrious exponent. Victor Meyer was born in 1848, and after filling the professorial chairs at Stüttgart and Zürich respectively was appointed professor at Göttingen on Wöhler's death in 1885, and finally went over to succeed Bunsen at Heidelberg in 1889. His labours in chemical science have related chiefly to nitro-compounds and to thiophen, while his name will go down to posterity in connexion with his method for determining the vapour density of volatile compounds. He has added not only considerably to our knowledge of organic chemistry, but has afforded us methods of gaining an insight into the constitution of compounds.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Kremnitz, a well-known surgeon of Bucharest, son-in-law of, and formerly assistant to, Professor Adolf von Bardeleben, of Berlin.

QUEEN'S COLLEGE, BELFAST.—At the class examinations held at the close of the summer session the following prizes were awarded, viz.:—Botany—Senior: Archibald George Heron. Junior: Charles James Ross, B.A.; Robert Alexander Stewart and John Stewart Ferguson Weir (equal); and John Armstrong and Robert Stanton Woods (equal). Practical Chemistry—Senior: John Elder MacIlwaine. Junior: Joseph Stewart and Hugh Barkley Steen. Medical Jurisprudence—George Jefferson, Patrick Park, and Hugh Donnelly. Systematic Pathology—Arthur Berry M'Master and Robert Alister Little Graham. Practical Pharmacy—Robert M'Carrison; and Alexandrina Crawford Huston and John Weir West (equal).

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the first examination of the Board in the subjects indicated under the five years' regulations, viz.:—

Part I., Chemistry and Physics:

Anthony, Christie Muthuswamy, Guy's Hospital.
Ball, Charles Rowan Anthony, Cambridge University.
Barnes, Walter Biscoe, University College, Bristol.
Bartlett, John Allen, University College, Bristol.
Beane, Robert Leonard, St. Thomas's Hospital.
Blunt, Thomas Edward, London Hospital.
Bolton, Frank Elliott, University College Hospital.
Boyd, Malcolm Ogilvy, Oxford University.
Bramhall, Charles, London Hospital.
Brayne, Robert Edward, Guy's Hospital.
Brierley, Charles Isherwood, Yorkshire College, Leeds.
Burgess, Harold Lynch, London Hospital.
Butterworth, Rupert, St. Mary's Hospital.
Cheese, Frederick William, St. Bartholomew's Hospital.
Clark, John Wilders Hambly, London Hospital.
Cock, Frederick, Charing-cross Hospital.
Collins, Reginald Thomas, Guy's Hospital.
Conolly, Noel Alfred William, St. Bartholomew's Hospital.
Cox, Clement Harlow, Mason College, Birmingham.
Cox, Ernest Alfred, King's College Hospital.
Crampton, Walter, University College, Liverpool.
Cresswell, Frederick Williams, St. Mary's Hospital.
Croly, Henry Pennington, London Hospital.
Curtis, George William, University College Hospital.
Daft, Leonard, Firth College, Sheffield.
Day, Charles Frederick, Private Study.
Dermott, Edward James, University College, Bristol.
Dickinson, Charles Marshall, London Hospital.
Doble, Henry Tregellas, St. Mary's Hospital.
Downes, Thomas William Hardwick, St. Thomas's Hospital.
Drawbridge, Wilfred Ralph Leycester, St. Bartholomew's Hospital.
Dutton Hugh Reginald, Middlesex Hospital.
Eames, Thomas Richard, Owens College, Manchester.
Edginton, Lewis Spencer, London Hospital.
Elder, George Tathar, St. Mary's Hospital.
Ellis, Francis Heygate, St. Bartholomew's Hospital.
Evans, George Jewel, St. Mary's Hospital.
Everett, Hastings Footman, London Hospital.
Ewen, Gerald Sydney, St. Bartholomew's Hospital.
Forster, Matthew, Cambridge University.
Fullagar, Walter Swainson, St. Thomas's Hospital.
Furnivall, Henry Wallace, University College Hospital.
Gardner, Harry, Firth College, Sheffield.
Gould, Alexander Cyril, St. Mary's Hospital.
Gregory, Arnold, Yorkshire College, Leeds.
Griffith, William Henry, University College, Liverpool.
Grogono, Eric Walter, London Hospital.
Gromitt, John William, Guy's Hospital.
Hayes, George Sullivan Clifford, Guy's Hospital.
Hood Basil, Charing-cross Hospital.
Hubbard, Adrian Russell Fortesque, Charing-cross Hospital.
Hughes, Geoffrey Wallace Grainger, King's College Hospital.
Hutchinson, Thomas, Mason College, Birmingham.
Jackson, Francis William, St. Bartholomew's Hospital.
Jiméniz, Ricardo Suis, Guy's Hospital.
Jobson, Frederick Cuthbert, Westminster Hospital.
Jones, Reginald Lewis, Middlesex Hospital.
Jones, William Watkin Cadwaladr, Guy's Hospital.
Lawrence, Charles John Montagu, Owens College, Manchester.
Leach, Richard Ernest Howell, St. Thomas's Hospital.
Leeming, Alfred, Owens College, Manchester.
Lewellyn, John Woodruff, University College and Cardiff.
Lewis, Ivor Cadwaladyr, St. Bartholomew's Hospital.
Lewis, John Lloyd, London Hospital.
Lowe, George Carter, Guy's Hospital.
Lowsley, Owen Leonard, St. Mary's Hospital.
Lund, John Knowles, Mason College, Birmingham.
McQueen, John Falconer, Clifton Laboratory, Bristol.
MacDowall, William M'Dowall, London Hospital.
McGuire, Herbert Vincent, University College, Liverpool.
Major, Hugh Marcus, St. Mary's Hospital.
Marshall, Reginald Prynne, Guy's Hospital.
Martyn, Frank Dérécourt, Westminster Hospital.
May, Charles Montague Neale, St. George's Hospital.
Miéville, George Christian Blake, University College Hospital.
Miles, Thomas George, Guy's Hospital.
Milner-Moore, Edward Henry, St. Mary's Hospital.
Miskin, Albert Francis, St. Thomas's Hospital.
Moir, Gordon, Guy's Hospital.
Morgan, Frank, Westminster Hospital.
Morris, Herbert William, Guy's Hospital.
Morris, Leslie Miles, St. Bartholomew's Hospital.
Morrison, Harold, Yorkshire College, Leeds.
Moyle, Reginald, Guy's Hospital.
Neville, Thomas Crofts, St. Bartholomew's Hospital.
Osburn, Arthur Carr, Guy's Hospital.
Owen, Charles Lewis Claude, St. Bartholomew's Hospital.
Parbury, Frederick Denis, St. Bartholomew's Hospital.
Parsons, Wilfred, University College Hospital.
Petrie, Alexander Sturrock, St. Bartholomew's Hospital
Phillips, Nathaniel Richards, University College, Cardiff.
Phipps, Charles Arthur Gayer, Owens College, Manchester.
Piggott, Allen Pledger, Pharmaceutical Society's School.
Powell, James Farquharson, St. George's Hospital.
Prall, Sydney Lionel, Guy's Hospital.
Pye-Smith, Charles Derwent, Firth College, Sheffield.

Reed, Keppel Hart, St. George's Hospital.
Richards, Thomas, University College, Cardiff.
Rivaz, Percy Montgomery, Nonconformist Grammar School, Bishops Stortford.
Rivière, Bernard Beryl, St. Paul's School, West Kensington.
Roberts, William Owen, Guy's Hospital.
Round, Harold, Mason College, Birmingham.
Rowlands, Moses John, University College, Cardiff.
Rugg, Godfrey Faussett, University College Hospital.
Ryley, Charles, St. Mary's Hospital.
Sampson, Bernard Moore, St. Thomas's Hospital.
Sansom, Bertrand Eli, St. Thomas's Hospital.
Scott, Maitland Bodley, St. Bartholomew's Hospital.
Serpell, Hugh Hamilton, St. Bartholomew's Hospital.
Sewell, Henry George, London Hospital.
Shadwell, Lancelot Walter, St. George's Hospital.
Shannon, Stanley Samuel Howard, Guy's Hospital.
Sharpley, Christopher Wilfred, Yorkshire College, Leeds.
Snell, John Percy Brooking, Middlesex Hospital
Stuart, Francis Arthur Knox, St. Mary's Hospital.
Stusser, Israel, London Hospital.
Talbot, Francis, Birkbeck Institute.
Traylen, Charles Leonard, London Hospital.
Trimmer, Francis Inman, London Hospital.
Upcott, Harold, St. Thomas's Hospital.
Vaughan, Walker Frederic Hamilton, St. Mary's Hospital.
Walker, John, St. Thomas's Hospital.
Walters, Joseph, University College, Cardiff.
Wetherell, Marmaduke Cordeux, Guy's Hospital.
Wilson Geoffrey Plumpton, London Hospital.
Wood, Walter James, University College Hospital.
Wood, William Vincent, Cambridge University and St. Bartholomew's Hospital.
Woodwark, Charles Stuart, St. Bartholomew's Hospital.
Wroughton, John Henry, St. Bartholomew's Hospital.

Part II., Practical Pharmacy:

Agate, Henry St Arnaud, St. Mary's Hospital.
Armitare, John James, St. Thomas's Hospital.
Bastian, William, University College Hospital.
Batchelor, Ferdinand Stanley, Guy's Hospital.
Bazalgette, Sidney, St. Thomas's Hospital.
Bishop, Darell Winn, Oxford University and St. Mary's Hospital.
Blick, Penn William Curle, Oxford University.
Bond, Frank Fouracre, Westminster Hospital.
Braddock, William, Owens College, Manchester.
Braugwin, Charles Harold, Guy's Hospital.
Bridge, John Croswaithe, Middlesex Hospital.
Brierly, Charles Isherwood, Yorkshire College, Leeds.
Court, Edward Percy, St. Bartholomew's Hospital.
Crampton, Walter, University College, Liverpool.
De Brent, Harold John, St. Thomas's Hospital.
Dudding, John Scarborough, London Hospital.
Dulgan, Victor John, St. Bartholomew's Hospital.
Dunstan, Robert, London Hospital.
Dutton, Hugh Reginald, Middlesex Hospital.
Edwards, David Richard, University College, Liverpool.
Forward, Ernest Lionel, St. Thomas's Hospital.
Foss, Edwin Vincent, University College, Bristol.
Fox, Hugh Watson, Guy's Hospital.
Froggatt, George Ernest, New Zealand and Middlesex Hospital.
Gibson, Thomas, St. Thomas's Hospital.
Goldie, Walter Leigh Mackinnon, St. Mary's Hospital.
Gray, William Harrington, London Hospital.
Griffith, Richard, Cambridge University and London.
Hackney, Gordon Herbert, University College Hospital.
Howell, Trevor, University College Cardiff
Howkins, Cyril Henry, Mason College, Birmingham.
Howroyd, James Edwin, Yorkshire College, Leeds.
Huelin, Lewis William, St. Mary's Hospital.
Hughes, Norman Alexander Alymer, Yorkshire College, Leeds.
Humphreys, George Jacks, St. Bartholomew's Hospital.
Jeremy, Harold Rowe, London Hospital.
Johnson, William Jerrol Greaves, St. Bartholomew's Hospital.
Keeling, Hugh Nevill, Yorkshire College, Leeds.
Lakin, Charles Ernest, Middlesex Hospital.
Lewis, George Jepson, Guy's Hospital.
Lindsey, Eric Craigie, St. Mary's Hospital.
Littlejohn, Edward Salterne, University College Hospital.
Lund, John Knowles, Mason College, Birmingham.
Maunsell, Bertram Sydney Osmund, St. Bartholomew's Hospital.
Mason, Alfred, Middlesex Hospital.
Meaden, Alban Anderson, St Bartholomew's Hospital.
Miles, William Percival, St. Bartholomew's Hospital.
Miskin, Albert Francis, St. Thomas's Hospital.
Morrish, William John, St. Mary's Hospital.
Moses, David Assur Henry, St. Bartholomew's Hospital.
Nash, Arthur Charles, Guy's Hospital.
Nesfield, Vincent Blumhardt, St. Mary's Hospital.
Pearson, Roland Wilfred, Owens College, Manchester.
Penfold, Fred Bailey, Middlesex Hospital.
Price, Ernest Walters, St. Bartholomew's Hospital.
Raven, Hugh Milville, St Mary's Hospital.
Raw, Herbert Harland, St. Bartholomew's Hospital.
Rice, Frank Melville Pitcairn, St. Bartholomew's Hospital.
Richards, Thomas, University College, Cardiff.
Rutherford, Randolph Henry Neilson, University College, Bristol.
Roberts, Earnest, Guy's Hospital.
Roper, Richard Snelling, Guy's Hospital.
Sale, John Caruthers, St. Bartholomew's Hospital.
Scot, Edward Spencer, London Hospital.
Sewell, Henry George, London Hospital.
Spalding, Archibald Denize, London Hospital.
Stansfield, Frederick Joseph, Yorkshire College, Leeds.
Stokers, Percy Southwell, Firth College, Sheffield.
Tayler, Frederic Ernest, St. Bartholomew's Hospital.
Tayler, Henry Christopher, St. Mary's Hospital.
Thompson, William Atkin, Owens College, Manchester.
Traylen, Charles Leonard, London Hospital.
Tweedie, Alexander Robert, St. Bartholomew's Hospital.
Ward, Bernard Joseph, Mason College, Birmingham.
Ward, Oswald Erasmus, Mason College, Birmingham.
White, Charles Vaughan, St. Thomas's Hospital.
Whitwell, Hugh, St. Bartholomew's Hospital.
Willey, Frederick, Yorkshire College, Leeds.
Winder, Maurice Guy, St. Bartholomew's Hospital.

Part III., Elementary Biology:

Agar, Samuel Annesley, London Hospital.
Alleyne, Evelyn Addison Wentworth, St. Mary's Hospital.
Archibald, Richard James, St. Thomas's Hospital.
Bartlett, Edward Leslie, St. Mary's Hospital.
Beane, Robert Leonard, St. Thomas's Hospital.
Beet, William Ashley, London Hospital.
Benson, Alick Cole, St. Paul's School, West Kensington.
Beverley, Kenneth Harold, University College Bristol.
Bird, Albert Edward, Owens College, Manchester.
Bolton, Frank Elliott, University College Hospital.
Bourns, Frank, Westminster Hospital.
Bramhall, Charles, London Hospital.
Brown, Robert Dixon, St. Thomas's Hospital.
Chell, George Russell Haines, Mason College, Birmingham.
Collins, Reginald Thomas, Guy's Hospital.
Connell, Harry Bertram, Mason College, Birmingham.
Crowther, Sydney Nelson, Westminster Hospital.
Daft, Leonard, Firth College, Sheffield.
Darbyshire, Harold Stewart Casson, Firth College, Sheffield.
Davies, Thomas Sidney, University College, Bristol.
Doble, Henry Tregellas, St. Mary's Hospital.
Eager, Mervyn, King's College Hospital.
Edginton, Lewis Spencer, London Hospital.
Fletcher, Harold, London Hospital
Gater, Arthur William, Guy's Hospital.
Gill, George Frederick, St. Bartholomew's Hospital.
Goldsmith, Hubert St. George, St. George's Hospital.
Gonin, Bertram Winter, St. Mary's Hospital.
Goodall, Alexander, St Bartholomew's Hospital.
Gover, Henry Arthur Sidney, St. Mary's Hospital.
Grogono, Eric Walter, London Hospital.
Hirsch, Leo, Grant Medical College, Bombay.
Holford, Christopher Tredwell, St. Thomas's Hospital.
Huddurt, Cuthbert Edmund Arnold, London Hospital.
Hughes, William Shelbourne, Charing-cross Hospital.
Ide, Harry, Charing-cross Hospital.
Lambert, Francis Courtenay, St. Mary's Hospital.
Lawrence, Charles John Montagu, Owens College, Manchester.
Leach, Richard Ernest Howell, St. Thomas's Hospital.
Lewellyn, John Woodruff, University College, Cardiff.
Lewis, Robert Robinson, Middlesex Hospital.
Lloyd, John Daniel Stuart, Mason College, Birmingham.
McGuire, Herbert Vincent, University College, Liverpool.
Martin, William, St. George's Hospital.
Meiklejohn, Norman Sinclair, St. Paul's School, West Kensington.
Miller, Frederick William, King's College Hospital.
Miller, Guy Witton, St. Bartholomew's Hospital.
Milner-Moore, Edward Henry, St. Mary's Hospital.
Morgan, Frederick William, University College, Bristol.
Morgan, Lewis Wayne, University College, Cardiff.
Morris, Herbert William, Guy's Hospital.
Ommanney, Francis Montague Maxwell, Guy's Hospital.
Parbury, Frederick Denis, St. Bartholomew's Hospital.
Penfold, Fred Bailey, Middlesex Hospital.
Pitt, Robert Cecil, London Hospital.
Pye-Smith, Charles Derwent, Firth College, Sheffield.
Raymond, George, St. Thomas's Hospital.
Ring, Charles Augustus Eamonson, Guy's Hospital.
Rose, Richard Aubrey de Burgh, University College Hospital.
Sharpley, Christopher Wilfred, Yorkshire College, Leeds.
Soper, Arthur Walrond, Guy's Hospital
Tulloch, Forbes Manson Grant, St. Mary's Hospital.
Turtle, Godfrey de Bec, King's College Hospital.
Webster, James Ainsworth William, St. Mary's Hospital.
Wickert, Jacob Hodgson, London Hospital.
Woodruff, Hamilton Augustus, St. Bartholomew's Hospital.
Wright, Arthur Cyril Charles, St. Mary's Hospital.

The following gentlemen passed the First Examination of the Board in the subjects indicated under the four years' regulations:—

Part I., Chemistry, including Chemical Physics:

Bowen, Ernest John Hamilton, London Hospital and University College of South Wales, Cardiff.

Part II., Materia Medica:

Amsden, Walter, St. Bartholomew's Hospital.
Cator, Peter, St. Bartholomew's Hospital.
Cope, Ricardo, St. Bartholomew's Hospital.
Cragg, Edward Henry, Guy's Hospital.
Crispin, Edward Smyth, King's College, London.
Cubley, Arthur, Firth College, Sheffield, and University College, London.
Dewdney, Edward Lucius Day, King's College, London.
Eddison, Francis Ryalls, St. Bartholomew's Hospital.
Gray, Egerton, Queen's College, Cork, and London Hospital.
Hay-Coghlan, William Kedeagh, St. Mary's Hospital.
Jones, Thomas Burnell, St. Bartholomew's Hospital.
McDonnell, Edward Thomas, Catholic University, Dublin, and Queen's College, Belfast.
Miller, Walter George Douglas, Cambridge University and University College, London.
Mitchell, Arthur Henry MacNeill, St. Mary's Hospital.
Park, William Hodgson, Charing-cross Hospital.
Rowland, Robert Sibbold, Cambridge University and Guy's Hospital.
Turner, Walter Edward, St. Mary's Hospital.

Part III., Elementary Physiology:

Parlett, Frank, University College, Bristol.

UNIVERSITY OF LONDON.—At the Intermediate Examination in Medicine in July the following candidates were successful in the subjects indicated:—

EXAMINATION FOR HONOURS.*

Anatomy.—First Class: William Henry Willcox, B.Sc. (Gold Medal), St. Mary's Hospital. *Second Class:* William Gough, B.Sc., Yorkshire College.

Physiology and Histology.—First Class: William Gough (Exhibition and a Gold Medal), Yorkshire College; John F. Northcott (Gold Medal), Cambridge and Guy's Hospital; and Frederic Agar St. John, St. Mary's Hospital. *Second Class:* Ernest Alfred Miller, Guy's Hospital; and William Henry Willcox, St. Mary's Hospital.

Organic Chemistry.—First Class: William Gough, Yorkshire College; and William Henry Willcox (Exhibition and Gold Medal), St. Mary's Hospital.

Materia Medica and Pharmaceutical Chemistry—First Class: John Atkins, Guy's Hospital; Joseph Moreton, Owens College; and William Henry Willcox (Exhibition and Gold Medal), St. Mary's Hospital. *Second Class:* Isobel Sarah Bryson, London School of Medicine and Birkbeck Institute; Ernest Alfred Miller, Guy's Hospital; and Alfred Richard Spencer, University College.

* Honours candidates are arranged in each class in alphabetical order.

PASS LIST.

Entire Examination.—First Division: Louisa Hamilton and Mary Hannah F. Ivens, London School of Medicine for Women, and Donald Johnstone McGavin, Mason College. *Second Division:* William Fielding Addey, University College; Vernon Cyril Bensley, St. Mary's Hospital; Guy Black, St. Thomas's Hospital; Francis Dawson Blandy, Middlesex Hospital; Susila Anita Bonnerjee, London School of Medicine for Women; Percy Frank Braithwaite, Owens College; Charles Henry Bullen, Mason College; James Alfred Butler and Percy William Leopold Camps, Guy's Hospital; Thomas Chetwood, London Hospital; Harold Collinson, Yorkshire College; Thomas Evans, University College; Harriet Rosa Delo Ford, London School of Medicine for Women; Herbert George Frankling, London Hospital; Alexander Freear, St. Mary's Hospital; Walter Burgess Fry, St. Thomas's Hospital; Edward Lake Gowland, St. Mary's Hospital; Dudley George Greenfield, Guy's Hospital; Walter Clapham Hirst, Yorkshire College; Thomas Hoban, St. Thomas's Hospital; Ernest William Holyoak, John William Hunt, and Bertram Fowler Hussey, St. Mary's Hospital; Frederick Arthur Johns, London Hospital; Robert George Johnson, Medical School and University College, Bristol; Joseph Edward Judson, Owens College and Manchester Royal Infirmary; Robert Blair Kinloch, University College, Cardiff; Thomas Noy Leah, St. Mary's Hospital; George Lewin, Guy's Hospital; Alfred Ernest John Lister, St. Bartholomew's Hospital; Olive McDougall, London School of Medicine for Women; Maurice Taylor Male, University College; Edwin Morgan, University College, Cardiff; Frank Mayo Morris, London Hospital; Christine Mary Murrell, London School of Medicine for Women; Cyril Alfred Rankin Nitch, St. Thomas's Hospital; William Paynter Noall, Owens College and Manchester Royal Infirmary; Harold Rothery Nutt, St. Mary's Hospital; Thomas Christian Orford, Owens College; Hugh McDowall Parrott, Guy's Hospital; William Edward Peck and Arthur Robert George Pocock, University College; Herbert Dean Pollard, London Hospital; Bryan Ellis Reynolds, University College; John Evans Richards, Charing-cross Hospital; Charles Archibald Scott Ridout, St. Bartholomew's Hospital; Bernard Hamilton St C. Roberts, Mason College; Florence Robinson, London School of Medicine for Women; Walter George Rogers, University College, Cardiff; Edward Mello Saunders, King's College; Cuthbert Fennessy Selous, St. Thomas's Hospital; Margaret Sophia Sharp, London School of Medicine for Women; Hugh Frederick Sheldon, Owens College; Frederick Blenkinsop Skerrett, B.Sc., St. Thomas's Hospital; Edwin Stott, Owens College and Guy's Hospital; Eric Wilson Danby Swift, University College; Christopher Thackray, University College, Sheffield; Robert Lewis Thornley, St. Bartholomew's Hospital; Harold John Van Praagh, St. Mary's Hospital; John Samuel Williamson, St. Bartholomew's Hospital; Louisa Woodcock, London School of Medicine for Women; Guy Theodore Wrench, Guy's Hospital; and Philip Roscoe Wrigley, Owens College.

Excluding Physiology.—First Division: Wm. Panckridge Panckridge, Middlesex Hospital; Arthur Wellesley Penrose, Guy's Hospital; and Arthur Tregelles Pridham, St. Bartholomew's Hospital. *Second Division:* Noel Charles Beaumont, St. Bartholomew's Hospital; Alfred John Vernon Betts, Westminster Hospital; Josephine Brown, London School of Medicine for Women; John Ellis Chapman, Sheffield; Lewis Cook, Westminster Hospital; Francis Gerrard H. Cooke, London School of Anatomy and Birkbeck Institute; Margaret Bernard Dobson, London School of Medicine for Women; Alfred Gordon Ede, St. Bartholomew's Hospital; Charles Edward Etheridge, Middlesex Hospital; William Ferris, St. Mary's Hospital; John Edmund Francis, University College; Alfred Jones, London Hospital; Brinley Richard Lloyd, University College, Cardiff; Syed Abul Mahmood, University College; Patrick Thurburn Manson and Oswald Marriott, Guy's Hospital; James Cole Marshall, St. Bartholomew's Hospital; Michael Foster Ranney, London Hospital; Ernest Russell-Risien, St. Bartholomew's Hospital; William Edward Ruttledge, University College; Mary Ethel S. Scharlieb, B.A., London School of Medicine and Birkbeck Institute; Francis Williams Sheppard, St. Bartholomew's Hospital; Nigel Frampton Stallard, Percy Taylor H. Stedman, and Charles Wynn Wirgman, University College.

Physiology only.—Second division: Charles Richard Brown, Harold Burrows, William Henry Cazaly, B.A., and John Moore Collyns, St. Bartholomew's Hospital; Guy Hemming Coltart, Westminster Hospital; Wilfred Henry Coltart, Birmingham Medical School; Mabel Eliza Cousins, London School of Medicine for Women; John Bernard Davey, Middlesex Hospital; Alec. Densham, Guy's Hospital; Susan Jane H. Eastwick-Field, Royal Free Hospital and London School of Medicine; Frederick Fenn Elwes, Middlesex Hospital; Eric Evans, London School of Medicine for Women; Thomas Heber Fox, Yorkshire College; Herbert Bowly Gibbins, St. Bartholomew's Hospital; Ernest Cutcliffe Hadley, Mason College; Philip Maynard Heath, University College; Edward Cecil Brearey Ibotson, Guy's Hospital; Seymour Alfred Millen, St. Bartholomew's Hospital; Herbert Henry Mills, Westminster Hospital and King's College; James Robert Morton, London Hospital; Bertram Wilmore Moss and Edward Erratt Parrett, B.A., Guy's Hospital; Charles Gabriel Seligmann, St. Thomas's Hospital; Walter Grahame Stewart, Guy's Hospital; Philip Graham Stock, Bristol Medical School; Margaret Helen Style, London School of Medicine for Women; John Frederick Walker, London Hospital; Albert John Walton Wells, St. Bartholomew's Hospital; and Robert Kardley Byam Wilmot, St. Mary's Hospital.

UNIVERSITY OF EDINBURGH.—The following degrees were conferred on July 31st:—

Degree of Doctor of Medicine.—‡Sol Jervois Aarons, Australia, M.B., C.M., 1896; Charles MacArthur Allan, Scotland, M.B., C.M., 1887; James Bird Brown, Scotland, M.B., C.M., 1890; James Murdoch Brown, Scotland, M.B., C.M. (with First-class Honours), 1874; †William Hartley Bunting, England, M.B., C.M., 1890; ‡John Ferguson Carruthers, Scotland, M.B., C.M., 1892; ‡Thomas Aldous Clinch, England, M.B., C.M., 1893; ‡Alexander Dall (M.A.), Scotland, M.B., C.M., 1894; Samuel Davidson, Scotland, M.B., C.M., 1893; ‡Richard Davies, England, M.B., C.M., 1892; Thomas Harrison Davison, M.B., C.M., 1883; John Josiah Douglas, Scotland, M.B., C.M., 1889; ‡John Buchanan Duff, Scotland, M.B., C.M. (with First-class Honours), 1893; James Churchill Dunn, New Zealand, M.B., C.M., 1893; Samuel Edgerley (M.A.), Scotland, M.B., C.M., 1891; *Friedrich Wilhelm Eurich, Saxony, M.B., C.M. (with Second-class Honours), 1891; Rufus Easson Evans, England, M.B., C.M., 1892; ‡John Hoggan Ewart, India, M.B., C.M., 1894; Francis Harold Fairweather, England, M.B., C.M., 1894; Arthur Graham Foljambe Forster, England, M.B., C.M., 1894; Arthur Foster, England, M.B., C.M., 1893; *William Edward Fothergill (M.A., B.Sc.), England, M.B., C.M. (with First-class Honours), 1893; ‡Hugh Ernest Fraser (M.A.), Scotland, M.B., C.M., 1891; *Thomas Alexander Wemyss Fulton, Scotland, M.B., C.M. (with First-class Honours), 1884; James Albert Gibson, Scotland, M.B., C.M., 1889; Thomas Anderson Glover, Scotland, M.B., C.M., 1894; ‡Edward Milliken Goldie, England, M.B., C.M., 1890; ‡Edmund Henri Gonin, England, M.B., C.M., 1890; ‡George Douglas Gray, Scotland, M.B., C.M., 1894 (*in absentiâ*); ‡Thomas Arthur Green, England, M.B., C.M., 1890; William Herbert Gregory, England, M.B., C.M., 1892; ‡Robert Grieve, England, M.B., C.M., 1894; John Howell Knight Griffiths, Wales, M.B., C.M., 1895; Arthur Erskine Herbert Cornelius Hallen, Scotland, M.B., C.M., 1889; Frederic Pollington Hearcer, Wales, M.B., C.M., 1889; ‡Ian Dalrymple Clark Howden Scotland, M.B., C.M., 1895; ‡Adam Jameson, Australia, M.B., C.M., 1883 (*in absentiâ*); Thomas Johnstone (M.A.), Scotland, M.B., C.M., 1885; †Thomas Bernard Kenny, British West Indies, M.B., C.M., 1894; James Kirk, Scotland, M.B., C.M., 1895; ‡Robert Knox, Scotland, M.B., C.M., 1892; Francis Kraemer (M.A.), Hungary, M.B., C.M., 1885; ‡John Adolphus Laing, New Zealand, M.B., C.M., 1894 (*in absentiâ*); ‡Cyril Lewis, Wales, M.B., C.M., 1891; †Frederick John M'Cann, Scotland, M.B., C.M. (with Second-class Honours), 1888; John William Macdonald, Nova Scotia, M.B., C.M., 1871 (*in absentiâ*); Angus Vallance Macgregor, Scotland, M.B., C.M., 1892; George Scott Macgregor, Scotland, M.B., C.M., 1888; ‡Henry Deedes Nutt Mackenzie, England, M.B., C.M., 1893; John Coull Mackenzie, Scotland, M.B., C.M., 1894; ‡George Henry Masson, West Indies, M.B., C.M., 1895; George Symers Mill, Scotland, M.B., C.M., 1889; †William Morrison (B.Sc.), Scotland, M.B., C.M., 1881; James Hay Murray, Scotland, M.B., C.M., 1892; Alfred James Meyrick Paget, England, M.B., C.M., 1895; James Pearse, England, M.B., C.M., 1893; Tom Pettey, England, M.B., C.M., 1894; Andrew Philip, Scotland, M.B., C.M., 1893; George Wilfred Pollard, England, M.B., C.M., 1892; George Loraine Kerr Pringle, Scotland, M.B., C.M., 1893; James Carson Rattray, Scotland, M.B., C.M., 1888; John Kildahl Richards, Australia, M.B., C.M., 1894 (*in absentiâ*); Edward Robinson, England, M.B., C.M., 1893; ‡John Grimmond Smith, Scotland, M.B., C.M., 1891; ‡James William Somerville, Scotland, M.B., C.M., 1887; Arthur Paget Stevenson, England, M.B., C.M., 1893; ‡John Steed, England, M.B., C.M. (with Second-class Honours), 1893; †James Purves Stewart (M.A.), Scotland, M.B., C.M. (with First-class Honours), 1894; Gavin Stiell, Scotland, M.B., C.M., 1881; Daniel Gibson Pearce Thomson, Scotland, M.B., C.M., 1883; William Thyne (M.A.), England, M.B., C.M., 1891; ‡Francis Ward, England, M.B., C.M., 1894; *David Arthur Welsh (M.A., B.Sc.), Scotland, M.B., C.M. (with First-class Honours), 1893; ‡Harry Whitfome, England, M.B., C.M., 1892; *John Mackie Whyte (M.A.), Scotland, M.B., C.M., 1882; Alexander Whytt, Scotland, M.B., C.M., 1894; Eugene Stephen Yonge, England, M.B., C.M., 1891; James Younan, India, M.B., C.M., 1890 (*in absentiâ*); and ‡Meredith Young, England, M.B., C.M., 1892.

* Those who have obtained gold medals for their theses.

† Deemed worthy of competing for the theses gold medals.

‡ Commended for their theses.

Degrees of Bachelor of Medicine and Master in Surgery (Old Regulations).—Frederick Anderson, Edinburgh; Richard William Anthony, Edinburgh; Hugh Llewellyn Apthorp, Bedford; James Reginald Atkinson, Crewe; §Harold Sherman Ballantyne, B.Sc., Eskbank, Midlothian; Bertram Mayhew Bone, Lancaster; Satis Chandra Bose, Edinburgh; Francis Wesley Broadbent, Leicester; Smith Osborne Browne, Londonderry; Charles John Caddick, West Bromwich; Lawson Millar Cairns, Bridgend, Langholm; Selwyn Gurney Champion, Burgess Hill, Sussex; Manmatha Nath Chaudhuri, Calcutta; George Lyall Chiene, Edinburgh; Bernard Ramsay Craig Christie, Chryston, Lanarkshire; William Cobden-Rowlands, Brecon, South Wales; Agnes Irene Sinclair Coghill, Ventnor, Isle of Wight; Lewis Archibald Crooks, Whitehall, Black River, Jamaica; Thomas Walter Alfred Daman, Edgbaston, Birmingham; William Gordon Donald, Bridge of Allan, N.B.; Stanley Ducat, Warslap, Arbroath; Robert William Thomas Ewart, Ellerslie, Moffat; Stewart Faed, Edinburgh; ‖William

Digitized by Google

Finlay, Edinburgh; John George Forbes, Edinburgh; Harry Fowler, Edinburgh; Robert Gellatly, Fairfield, Manchester; John Frank Gibbon, Edinburgh; William Herbert Goldie, Edinburgh; James Graham, Joppa, Midlothian; Thomas Parker Greenwood, B.Sc., Cononley, *vid* Keighley, Yorks. James Grieve, Viewpark, Lesswade; §William Frederic Harvey, M.A., Edinburgh; Joseph Chambers Hastings, Dunwiley, Stranorlea, co. Donegal; John Henderson, Edinburgh; Edwin Henry Irwin, Armagh; Andries Lourens de Jager, Edinburgh; John Boyd Jamieson, Edinburgh; Thomas Nicol Johnston, Midlothian; Charles Brand Johnstone, Birkenhead; David Thomas Rocyn Jones, Rhymney; ‖Evan Harries Jones, Rhyl, North Wales; ‖Leslie Kingsford, Thornton Heath, Surrey; Gavin Liddell, B.A., Mornington, Dunedin, New Zealand; Lewis Stephens Lyne Liddell, Portobello; Arthur Weir Limont, Alnwick, Northumberland; §George Carmichael Low, M.A., Monifieth, Forfarshire; John Scott Lyle, Newtownstewart, co. Tyrone; David McAskie, Creery, Magheraeriggan, Castlederg, co. Tyrone; Mary Ross McDougall, Edinburgh; James John Lister Macfarlane, Capelaw, Colinton; Charles Clark Macmillan, Hamilton, Victoria, Australia; Angus Duncan Macpherson, M.A., Edinburgh; Harold Malcolmson, Holywood, co. Down; Mack Walter Manuk, London; §Edwin Matthew, M.A., Nairn; Arthur Grove Naylor, Gloucester; Thomas Matheson Ness, M.A., Edinburgh; John Newington, Goodhurst, Kent; James Nicoll, London; Harold Nuttall, M.A., Liverpool; James Harold Patterson, Edinburgh; Edward Laurence Phillips, Bacup; Winifred Jane Pierce, Ajmere, Rajpootana, India; Peter Rattray, Dundee; Robert Railston Richardson, Edinburgh; John Rees Roberts, B.Sc., Denbigh; Edward Charles Robertson-Fullarton, Glasgow; Isidore Eugene Rosenstein, Aberdeen; Thomas Arthur Ross, Edinburgh; Robert Selby, Port William, Wigtownshire; Dosabhoy Cursetjee Sethna, Bombay; James Adam Shoolbread, Corstorphine, Midlothian; Ethel Louie Starmer, Norwich; Thomas Herbert Stevenson, Belfast; James Prain Sturrock (M.A.), Dundee; George Crewdson Thomas, Swainswick, Bath; Isabella Beattie Venters, Stirling; Frederick James Walden, Edinburgh; James Robert Hall Walker, Edinburgh; ‖Andrew Hutton Watt, Edinburgh; Adam Ramsay Wight, Windygates, Fife; Walter Galbraith Wight, Windygates, Fife; and Maurice Beresford Wright, Laurel Hill, Loughgall, co. Armagh.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—‖Bertram Cecil Robert Aldren, Malvern; Victor George Alexander, Portobello; ‖Theodore Robert William Armour, Edinburgh; Thomas Biggam, Laigh, Glenstorkadale, Leswalt, Wigtownshire; Robert Barclay Black, Edinburgh; Henry Wynne Boland, Dundee; Leonard Boyer, Sleaford, Lincs.; William Burns (M.A.), Lochty Bank, Carnoustie; David Clow, Kelso; § Charles Miner Cooper, Draycot, Weston-super-Mare; Llewelyn Wynne Davies, Llansilen, Oswestry; Joseph Espie Dods, Edinburgh; Granville Landsborough Findlay, Warriston, Largs, Ayrshire; James Forrest, Blackburn; Gideon Fourie, Edinburgh; William Hope Fowler, Edinburgh; § John Smith Fraser, Edinburgh; Andrew Gibson, Paisley; William Gorrie, Dundee; § William Hamilton, Middlesbrough; Wroughton Gerald Heath; Rowland Hill, Portobello; Guy Bertram Hollings, London; Patrick Kinmont, Edinburgh; Frederick Oakley Lasbrey, Bedford; Alexander Bremner MacCarthy, West Allington, Bridport Dorset; Thomas John Tyndale M'Hattie, Ealing; Ian Lamont MacInnes, Edinburgh; James Wilson M'Intosh, Edinburgh; William Ernest M'Kechnie, Edinburgh; ‖John Malcolm, Thurso; William Martin, Ballynahinch, co. Down; Francis Watson More, Edinburgh; Edward Fox M'Leod Neave, Dundee; John Hunter Park Paton, Duddingston, Midlothian; Alexander Howard Pirie (B.Sc.), Dundee; Robert George Riddell, Cocklaw, Cockburnspath, Berwickshire; § James Duncan Slight (M.A.), Portobello; William Maule Alexander Smith, Wellbank by Dundee; William Ralph Somerset, Manchester; ‖John William Struthers, Edinburgh; George Alves Vincent, Port of Spain, Trinidad, B.W.I.; Charles Percivale Bligh Wall, London; William Mackenzie Wilson, Stockton-on-Tees.

§ Indicates that the candidate has passed the examinations with First-class Honours.

‖ Indicates that the candidate has passed the examination with Second-class Honours.

The Ettles Scholarship has been awarded to Edwin Matthew, M.A., M.B., C.M.; the Beaney Prize in Anatomy and Surgery to Charles Miner Cooper, M.B., Ch.B.; the Murchison Memorial Scholarship in Clinical Medicine to Percy Theodore Herring, M.B., C.M.; the Buchanan Scholarship in Gynæcology to William Herbert Goldie, M.B., C.M.; the James Scott Scholarship in Midwifery to Charles Miner Cooper, M.B., Ch.B.; the Gunning Victoria Jubilee Prize in Practice of Physic to John Forbes, M.A., M.B., C.M.; the Milner Fothergill Gold Medal to William Edward Fothergill, M.A., B.Sc., M.D., C.M.; the Wightman Prize in Clinical Medicine to Ernest Francis Bashford; and the Pattison Prize in Clinical Surgery to Robert William Mackenna, M.A.

Degree of Doctor of Science.—Frederick Beddow, B.Sc., Alexander Morgan, M.A., B.Sc., and Gregg Wilson, M.A., B.Sc (*in absentiâ*).

Degree of Bachelor of Science.—Ernest Masson Anderson, ¶Alexander Brown, M.A., George Brownlee, and Alexander Campbell Mackay, M.A. *In the Department of Public Health:* Francis Maitland Gibson, M.B., C.M., B.Sc. (Pure Science); Robert Charles Mac-Watt, M.B., C.M.; Bahadhur Kaikhushro Nariman, M.B., C.M.; and Alexander Oswald Cowan Watson, M.B., C.M. *In the Department of Agriculture:* Sydney Francis Ashby, William Grice Mason, Samuel Milligan, M.A., and John Oderton Peet.

¶ Passed with Special Distinction in Mathematics and Natural Philosophy.

In the Faculty of Science the Vans Dunlop Scholarship in Chemistry has been awarded to James Patrick Longstaff and Allan W. C. Menzies, M.A., equal.

The following is an official list of candidates who have completed the first, second, and third professional examinations for degrees in Medicine and Surgery:—

First Professional Examination.—R. V. C. Ash, R. T. Baillie, R. A. Bellilios, A. N. Bond, R. J. Bradley, A. J. Brock, Alfred Brown, E. E. Brown, G. M. Brown, James Brownlee, Henry Buist, E. P. Calder, S. M. D. Campbell, T. F. Cavanagh, C. C. Choyce, B.Sc., R. E. Collins, B.A., P. T. Copeland, John Dalgliesh, W. H. Dickinson, J. L. Duncan, William Eggeling, Alexander Emslie, O. J. Evans, John Ferrier, A. H. Firth, M.A., Gavin Forrest, Catherine Fraser, Alexander Frew, H. J. George, Gavin Grey, M.A.; M. D. Gulland, A. F. Haegert, A. R. Hallam, A. M. Hamilton, William Hamilton, N. C. R. Hansen, R. A. J. Harper, D. C. Henry, L. A. Holcroft, L. J. Hood, C. W. Howe, A. E. Hunter, L. G. Hunter, Richard Imrie, A. R. Johnston, M.A., G. A. Jolly, Edgar Jones, A. C. Keay, Wm. Lee, E. W. Lewis, R. M. Liddell, C. H. Lindsay, Isabella Logie, Samuel Lyle, J. G. M'Bride, S. W. M'Clean, L. T. M'Clintock, Harriet M'Cleghry, J. B. M'Cutcheon, H. K. Macdonald, Wm. Macdougall, M.A., Alexander M'Ewan, P. F. M'Farlan, A. P. M'Gregor, N. F. MacHardy, John M'Kenzie, V. C. M'Laren, Evan Macmillan, K. D. C Macrae, A. M. Malcolmson, H. C. Martin, R. H. Martin, A. F. G. Masson, E. C. C. Maunsell, J. H. Meikle, M.A., B.Sc., W. H. Meyer, G. R. Mill, Joseph Miskelly, John Morrison, G. S. Murray, D. A. Ogilvie, George Pereira, A. C. Peterson, L. W. Pole, D. E. Pratt, W. H. Prentice, M.A., A. H. Reid, O. L. Rhys, Reginald Rorie, Laurence Rundall, H. W. Rusack, C. W. V. Rutherford, C. W. Saleeby (with distinction), R. A. Savage, E. T. Selkirk, J. F. Selkirk, T. B. Shaw, Daniel Smellie, J. A. Smith, M. M. Smith, T. A. Smyth, G. B. A. Speirs, M. M. Stevenson, S. S. Steyn, G. C. Strathairn, John Sullivan, David Sutherland, Paul Telles, H. P. Thompson, T. L. Thomson, P. S. Tillard, E. J. Tyrell, E. A. Walker, A. R. Wallis, C. E. Watts, A. G. Waugh, T. S. B. Williams (with distinction), C. C. Wilson, F. E. Wilson, James Woods, and R. T. Young, M.A.

Second Professional Examination.—W. J. Baird, C. A. J. A. Balck, F. M. Black, P. J. Bodington, Mary Booth, G. A. Brogden, W. J. D. Bromley, A. P. L. Brown, G. H. J. Brown, J. M. Buist, D. A. Callender, J. C. Carr, Morden Carthew, J. B. Cassels, Charles Chilton, J. D. Comrie, M.A. (with distinction), B. J. Courtney, H. B. Dodds (with distinction), D. R. Evans, David Ewart (with distinction), William Ewart, Hugh Faulkner, David Fenton, E. G. Ford, J. J. Galbraith, P. P. Ganteaume, B. K. Goldsmith, C. H. G. Gostwyck, George Haddow, P. W. Hampton, G. G. Hay, A. C. Heath, P. H. Henderson, A. M. Holmes, D. J. Hugher, A. M. Hutchison, W. T. James, P. F. Jardine, Thomas Jenkins, F. J. Jude, F. F. Kerr, J. W. Kerr, D. B. King, M.A., G. R. Laing, C. G. S. Leeds, L. S. Lessing, E. M. Lithgow, J. D. Lithgow, P. N. M. Macdonald, W. R. Macdonald, P. A. Maclagan, R. A. Macneill, L. W. Macpherson, E. W. Martin, F. N. Menzies, M. J. Menzies, D. B. Merry, R. M. Mitchell, H. A. D. Moore, Alexander Mouat, W. A. Murray, A. W. Nankervis, A. C. Neethling, T. P. Oates, T. S. A. Orr, William Park, J. H. Paterson, J. J. L. de Pavillet, R. N. Pringle, S. C. Pritchard, F. G. Ralston, William Reid, M.A., T. R. Robertson, G. B. Robinson, J. G. Ross, J. M. Ross, A. J. Ryle, Aneesa Sayba, J. T. Scott, Sutherland Simpson, B.Sc. (with distinction), A. B. Slater, C. E. Smith, Stephen Southall, W. C. Spooner, K. L. Teng, G. N. W. Thomas, J. A. Thompson, W. G. Thompson, George Thomson, John Thornhill, A. S. Trapaga, C. H. Watson, J. B. Wilson, and E. M. Young.

Third Professional Examination.—T. M. Alexander, A. E. Brookes, J. D. Cameron, Robert Crawford, R. M. Dalziel, F. H. Dommisse, C. L. Dunn, D. D. Farquharson, Alexander Fordyce, A. E. Goldie, J. M. Gray, E. R. Grey, Græme Hamilton, Thomson Henderson, A. M. Hutchinson, B. S. Hyslop, Robert King, James Leggate, P. A. Leighton, E. M. Lithgow, William Lockerbie, J. S. Low, B.Sc., P. L. M'All, John M'Gregor, Robina M'Gregor, D. A. Macvean, J. F. Martin, Ruth Massey, J. W. Mathewson, B.Sc., C. W. F. Melville, L. H. B. Mills, W. J. Nutter, T. A. Price, Robert Pugh, J. M. Reid, J. H. Rhodes (with distinction), Ibrahim Shalaby, G. F. B. Simpson, J. A. C. Smith, F. H. Stirling, William Tarr, A. K. Traill, and K. C. Verley.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

—At the July sittings of the Conjoint Board of the three coöperating authorities above named, held in Glasgow, the following candidates passed the respective examinations:—

First Examination: Five Years' Course.—John M. Morton, Glasgow (with distinction); John Leeming Stephenson, Padiham, Lanc.; John M'Intyre, Rothesay; Donald Duff, Glasgow; Rona Lockhart, Glasgow; Robert Wardlaw, Linlithgowshire; Archibald M'Millan, Glasgow (with distinction); William H. Duncan, Mid-Calder; P. Mackellar Dewar, Glasgow; Charlotte M'Crea, Glasgow; Martin Francis Cusack, Mitchelstown; Evelyn John Evatt, Liverpool; Kallyani Pado Chatterjee, Calcutta; John O'Connor, Ireland; James Joseph Lynch, Mallow; James Charles Galloway, Carlisle; Joseph Edwin Cooper, Egton, Yorkshire; Charles Henry Nash, Cork; and Samuel V. T. Barr, Hull.

First Examination: Four Years' Course.—Charles Alex. R. Hall, Culcutta; David Charles Blair, Redcross, Wicklow; Robert Roberts, Llanddensant, Wales; Arthur Clarence Turner, Copake, New York; James Graham, Dublin; and George A. Thompson, Darwen, Lancashire.

Second Examination: Five Years' Course.—Owen Felix M'Carthy, Cork; William John Buckmaster, Cork; Edward Michael M'Swiney, Limerick; David Fyfe, Glasgow; Charles M'Donnell, Limerick; John Norman Meade, County Cork; John Thomas Bradley, County Clare; William Ogilvy, Cambuslang; and William Arthur Benson, County Durham.

Second Examination: Four Years' Course.—Henry Rhys Battiscombe, Radnorshire; Robert Christie Reid, County Armagh; Thomas B. Saxby, Shetland; John Robertson, Aberfeldy; George Augustus Thompson, Darwen, Lanc.; John Thomas Farren, County Donegal; and Thomas Warren Colthurst, Somersetshire.

Third Examination.—James Moffat Inverarity, Dundee; Robert Stewart, Hamilton; Alexander Johnston Wilson, Newmains; William M'Farlane, Cambusnethan; James Ross, Ballymena; and James Dunlop, Glasgow.

Digitized by Google

Final Examination, and admitted Licentiate of the three Coöperating Authorities.—James Robertson Riddell, Pollokshields; Robert Hamilton Fleming, Glasgow; Alexander Ross, Glasgow; Ralph Sedgley Elvins, Handsworth; Robert Henry Munro, Coatbridge (with honours); George Herbert Arthur Taylor, Airdrie; Arthur Charles Adderley, Douglas, County Cork; John Dunlop, Crosshill (with honours); Griffith Llewellyn Jones, Talysarn, Carnarvon; T. Edmondston Saxby, Shetland; John Elliott, Glasgow; Arthur Emlyn, Glasgow; Joseph Sanderson, Glasgow; John Adam Campbell, Ainsworth, Bolton; William George Silvester, Edinburgh; Duncan M'Gregor, Aberfoyle; David Archibald Chalmers, Glasgow; Ernest Frederick Lionel de Jersey, Guernsey; Thomas Spinks Ross, County Antrim; Edgar Huss Sheldon, Leicester; David Charles Rowlands, Edinburgh; Thomas Dow Waddell, Glasgow; and George Barthorpe Simpson, Edinburgh.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The annual meeting of this association was held at the College of Medicine, Newcastle-on-Tyne, on July 29th and 30th. Dr. W. Julius Mickle, the retiring President, was succeeded by Dr. T. W. McDowall, superintendent of the Northumberland County Asylum, Morpeth. Dr. Urquhart, of James Murray's Royal Asylum, Perth, was selected as President-elect, and Dr. Robert Jones, of Claybury Asylum, Woodbridge, was appointed honorary general secretary, in succession to Dr. Percy Smith. An illuminated address was presented to Dr. Fletcher Beach, who had filled the office of general secretary for seven years. The Gaskell medal and prize was awarded to Dr. C. H. Bond, of Banstead Asylum. After the business meeting Dr. McDowall took up the office of President for the ensuing year, and delivered the presidential address on the Insane in India and their Treatment. He called attention to the defective provision of the care and treatment of the insane in India and said that it was entirely inadequate to the population. The officially known lunatics in India were 4311, or 1 in 70,000 of the population, whereas the last report of the Lunacy Commissioners gave a ratio of 3 lunatics to every 1000 of the population in England and Wales. There could be no doubt there were in India many others uncared for. In the native states there was only one asylum at Mysore; and in the portion of India under British rule there were only 24 asylums with a total of 4311 patients, of whom 1154 were criminals. The tyranny of caste requirements weighed heavily, and the requirements of "purdah" led to the almost total neglect of insane women in India. In the asylums officialism reigned supreme, the medical superintendents being army medical officers who had had little experience in asylum administration and the treatment of the insane. He suggested that asylums for insane women in India must be officered entirely by women, that the criminal element should be entirely removed to separate institutions, and that army medical officers should no longer be superintendents of asylums. He considered that medical women had no career in asylum practice in this country, but that, having gained some experience over here, they would be in a position to carry out much-needed reforms as far as concerned the treatment of insane women in India.—Dr. Eric France read a paper on Tuberculosis in the Insane—its Prophylaxis. He considered that, treatment of tuberculosis being at present very uncertain in its results, prophylaxis must be looked to as affording practically the only chance of reducing the death-rate from phthisis in asylums. Inhalation of tuberculous dust was the most frequent mode of infection in asylums. The most careful systems of ventilation in asylums were not attended by a corresponding diminution of the death-rate from phthisis in such institutions. Efficient ventilation did not prevent the dissemination of tuberculous dust in the wards. He considered that isolation was the only efficient method of preventing the spread of the disease, and to effect this early and absolutely accurate diagnosis must be arrived at. The physical signs being often masked in the insane, he considered the only method of accurate diagnosis to be the subcutaneous injection of minute doses of Koch's original tuberculin. He gave particulars of cases in which he had adopted this method of diagnosis.—Dr. Hayes Newington read a paper on Some Mental Aspects of Music.—Dr. Ford Robertson read a paper on the Normal Histology and Pathology of the Neuroglia in relation specially to Mental Diseases, accompanied by a microscopical demonstration. He combated the views of Bevan Lewis, Andriezen, and Weight as to the structure and functions of the neuroglia, considering it to be merely a supporting net-work for the nervous tissues consisting of cells with fibres radiating from them, and that the cells were not independent of the fibres, as had been taught.—Dr. W. A. Campbell read a paper on the Uses of Formol in the Neurological Laboratory, and illustrated his paper by a series of microscopical specimens. He subsequently read a paper on the Course of the Pyramidal Tract, illustrated by lantern demonstration.

MR. A. CAMERON SKINNER has been appointed secretary of the Victoria Hospital for Children in the place of the late Captain Blount.

LIVERPOOL CONVALESCENT INSTITUTION, WOOLTON.—The twenty-third annual report shows that during the year 1896 there were admitted 2305 patients, being a decrease of 84 on the previous year. The year opened with an adverse balance of £383 18*s.* 11*d.*, which had been reduced to £14 6*s.* 1*d.*, but it was to be regretted that owing to the amount expended on the drainage and the reduction of the balance brought from last year it had not been possible to augment the endowment fund by appropriating any portion of the special donations received during the year. The contribution from the Liverpool Hospital Sunday and Saturday Fund amounted to £275, and the annual subscriptions showed a total of £826, which, with £4385 7*s.* 8*d* received as payments for maintenance of patients, fell short of the expenditure by £14 6*s.* 1*d.*, balance due to the bank. On the whole, the report is considered satisfactory.

PRESENTATIONS TO MEDICAL MEN.—Mr. Hugh F. Hurst, L.R.C.P., L.R.C.S. Edin., has been presented by the Ambulance Classes of the Walker-on-Tyne centre of the St. John Ambulance Association, with a silver teatray as an appreciative recognition of his services as instructor to the classes.—Mr. Hugh Stott, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H., of Friern Barnet, on his leaving the neighbourhood has been the recipient of a solid silver tray and an elegantly illuminated address. The tray bears the following inscription: "Presented with an illuminated address to Hugh Stott, Esq., L.R.C.P., M.R.C.S., L.S.A., D.P.H. Lond., by a large number of friends, on the occasion of his leaving Friern Barnet, as a mark of esteem and gratitude for the many kind services rendered during the past sixteen years. July 23rd, 1897." At the same time Mrs. Stott was presented with a handsome gold bracelet set with diamonds.

TYNEMOUTH INFIRMARY.—A new wing has been added to the Tynemouth Jubilee Infirmary, North Shields, by the liberality of Colonel R. S. Donkin, M.P. for the borough of Tynemouth, and was formally opened by Earl Percy on Aug. 4th. The building is a very desirable addition to the accommodation of the institution and, moreover, produces a pleasing architectural effect. As a compliment to the donor it has been decided that it shall be called the "Ada Dryden Donkin Wing." It contains a ward measuring thirty-two feet by twenty-four feet, in which six cots for children and four beds for female patients will be placed, the remainder of the building being occupied by two isolation wards and by sitting-rooms and bedrooms for nurses; the basement is spacious and will be used as a store-room and boiler-room. The question of appointing a resident medical officer to the infirmary is under consideration, and Mr. H. S. Edwards, of Corbridge, has promised that, in the event of such an appointment being made, he will pay all expenses connected therewith for a period of three years and will, moreover, give a donation of 100 guineas.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, VENTNOR.—On July 31st, as announced in THE LANCET of that date, H.R.H. Princess Henry of Battenberg visited Ventnor for the purpose of laying the foundation-stone of a new block of houses which are in course of erection in connexion with the National Hospital for Consumption and Diseases of the Chest at Ventnor. The proceedings commenced with an address read by Dr. J. G. Sinclair Coghill, senior physician, the Princess's reply being read by Sir Richard Webster, the Attorney-General. The foundation-stone was a marble block bearing the following inscription:—"To the glory of God and in memory of his Royal Highness Prince Henry of Battenberg, K.G. This stone was laid by her Royal Highness Princess Henry of Battenberg, Governor of the Isle of Wight, 31st July, 1897." Mr. P. B. Burgoyne, the treasurer, stated that the building would consist of three houses, the cost of which

Digitized by Google

would be defrayed respectively by the estate of the late Mr. Armitage, R A, by Mr. John P. Muller, and by public subscription.

BEQUESTS AND DONATIONS.—The Board of Management of St. Mary's Hospital, London, has received £300 from the treasurer of Smith's (Kensington estate) Charity; also £1000 from the executors of the late Mrs. Overend, £300 from the executors of the late Captain E. Warriner, £100 from Mr. H. J. Allcroft, and £100 from the executors of the late Mrs. Williams.—The treasurer of Charing Cross Hospital, London, has received 100 guineas from the committee of the National Sporting Club; also £10,000 from the executors of the late Mr. David Brandon, being a payment on account of the residue of his estate; also a donation of £1000 from the Dowager Lady Loder for the endowment in perpetuity of a bed in memory of the late Sir R. Loder, Bart., M P., and £3000 from the executors of the late Mr. Andrew Guesdon, being the share assigned to the hospital from the residue of Mr. Guesdon's estate.—The committee of the Miller Hospital and Royal Kent Dispensary, Greenwich, has received a donation of £100 from the trustees of Smith's (Kensington estate) Charity.—The council of the Chelsea Hospital for Women, Fulham-road, has received £100 from the trustees of Smith's (Kensington estate) charity.—The committee of the North London or University College Hospital has received £1020 18s. being the amount collected by the nurses and students of the hospital; also from the People's Contribution Fund, £100.—The governors of the London Lock Hospital have received £200 from the trustees of Smith's (Kensington estate) Charity.—The treasurer of St. Thomas's Hospital, London, has received £933 from the executors of Mr. H. L. F. Morgan; also £5000 from the executors of Mr. W. A. Guesdon, £100 from the executors of Mr. Thomas Courtney, £90 from the executors of Miss E. Comber, £1000 from Mrs. Morgan for endowment of a bed, £1000 In Memoriam from "M. L. R.," £1000 from Mr. C. Gassiot as a Jubilee gift, and £105 from a governor as a Jubilee gift.—The board of the National Hospital for Consumption, Ventnor, Isle of Wight, has received a grant of £100 from the Worshipful Company of Goldsmiths.—The late Mrs. Ellen H. Harris has bequeathed £1000, and the late Mr. James Billing £500, to the Throat Hospital, Golden-square, London.—The treasurers of the Middlesex Hospital have received £10,000 from the executors of Mr. David Brandon, being a payment on account of the residue of his estate; also an anonymous donation of £500 towards the Cancer Ward, per Dr. A. F. Voelcker, and a donation of £157 10s. from the Worshipful Company of Fishmongers.—The committee of the North-Eastern Hospital for Children, Hackney-road, Shoreditch, has received a donation of £100 from the *Star* newspaper.—The executors of the late Mr. Thomas Hall have forwarded a legacy of £500 (less duty) and also a further sum of £225 to the Central London Ophthalmic Hospital, Gray's-inn-road, and a donation of £400 has also been received from Mrs. James Packe.—The committee of the Seamen's Hospital Society (*Dreadnought*), Greenwich, has received a donation of £500 from "An Admiral."—The board of the East London Hospital for Children and Dispensary for Women has received a donation of £100 from the Worshipful Company of Grocers, also £200 from the Worshipful Company of Goldsmiths.—The Committee of King's College Hospital, Lincoln's-inn, London, has received £100 from S.D.R S.D.—The secretary of the Royal Hospital for Diseases of the Chest, City-road, London, has received a donation of £100 from the trustees of Smith's (Kensington estate) Charity, and from the Fishmongers' Company a donation of fifty guineas.—The treasurer of Guy's Hospital, London, has received £10,000 from the trustees of the late Mr. W. A. Guesdon.—The Committee of the Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System, Regent's-park, London, has received from the executors of the late Mr. W. A. Guesdon £1000, and £100 from Mr. and Mrs. G. Robertson.—Sir J. W. Ellis has given 100 guineas towards the Victoria Endowment Fund for the Richmond Royal Hospital.—The following sums have been bequeathed by the late Mr. William Andrew Guesdon: Cardiff Infirmary, £3000; Swansea General and Eye Hospital, £2000; Merthyr General Hospital, £2000; Pembrokeshire and Haverfordwest Infirmary, £500; Rhyl Royal Alexandra Children's Hospital, £2000; Wrexham Infirmary, £500; and Carnarvonshire and Anglesea Infirmary and Dispensary, Bangor, £1000.—The late Rev. Monsignor Clarke, D.D., of Clifton, has bequeathed £100 to the Bristol Royal Infirmary and £100 to the Bristol General Hospital.—The late Colonel P. K. Seddon, J.P., of Gloucester, has bequeathed £1000 to the Grimsby General Hospital.—The late Mrs. Anne Muspratt, the widow of Dr. Sheridan Muspratt, a well known analytical chemist, has bequeathed the following amounts to Liverpool institutions: £500 to University College, Liverpool, for the foundation of scholarships; £200 each to the Royal Southern Hospital, the Northern Hospital, and the Liverpool Society for the Prevention of Cruelty to Children; £300 to the Children's Infirmary; besides several other bequests to local charities.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Close of the Session.

THE session of Parliament which began on Tuesday, Jan. 19th, was brought to a close on Friday, Aug. 6th. Prior to the prorogation a number of public and private Bills received the Royal assent, among the former being the Infant Life Protection Bill, the Scotch Public Health Bill, the Metropolitan Water Companies Bill, the Bill to increase the limit of age within which children are prohibited from taking part in dangerous performances, and the Poor-law Officers Superannuation Act (1896) Amendment Bill.

The Army Medical Service.

During the debate on the Appropriation Bill Mr. Price raised the question of the state of things in the Army Medical Service. He called attention to deficiencies in the number of candidates at different examinations for the service, and urged the Government to make a special effort to ascertain why it was that the medical profession avoided the service in spite of the concessions recently made with the object of attracting candidates. Mr. Powell-Williams, Financial Secretary to the War Office, replying to Mr. Price, said it appeared that the grievances of the service had reference more to conditions than to pay, and the former were at the present moment receiving the very earnest attention of the Secretary of State for War. For one thing, it was hoped that they might be able materially to reduce the length of service abroad.

Experiments on Living Animals.

On the same occasion Mr. Swift MacNeill raised this subject. He insisted that the Act of 1876 had been entirely nugatory, and that even when the inspectors saw the most cruel torture they could not raise a hand in protest. Sir M. White Ridley replied that it was not his business to express an opinion upon vivisection; his business was to carry out the Act of 1876 to the best of his ability; and he asserted most positively that not only during the time he had been at the Home Office, but also during that of his predecessors, the greatest possible care had been taken that licences should only be given to proper persons and that the Act should be carried out in the spirit as well as in the letter. He believed it was not possible to secure better inspection than at present. The hon. Member was opposed to the use of animals for experiments under any circumstances even for the benefit of mankind. He was not, however, supported in this by the majority of the people of this country, who were honestly persuaded that animals might under proper conditions be used as a means of discovering the most beneficial modes of alleviating human suffering.

HOUSE OF COMMONS.

THURSDAY, AUG. 5TH.

Cost of the Brook Hospital.

Mr. Pickersgill asked the President of the Local Government Board whether the cost of the Brook Hospital, recently erected by the Metropolitan Asylums Board, had been £64,000 in excess of the estimates presented to the Board and £50,000 in excess of the actual amounts of contracts entered into; and whether, before he issued a further order for expenditure in respect of the erection of this hospital, he would have inquiry made into the causes of this extraordinary excess.—Mr. Chaplin replied that the facts as regards the amount by which the cost of the hospital exceeded the amounts of the estimates and of the various contracts entered into were, he believed, as stated in the question. The managers had received a report from the committee of the hospital as to these expenses, and the consideration by them of the report had been adjourned. Before sanctioning a further loan the Local Government Board would very carefully consider all the circumstances connected with the actual expenditure and the increase of the cost over the estimates.

Metropolitan Asylums Board and the Care of Children.

Mr. Pickersgill asked the President of the Local Government Board what steps have been taken by the Metropolitan Asylums Board, under the new order, to provide accommodation for juvenile prisoners under

Digitized by Google

remand, and when such accommodation would be available.—Mr Chaplin replied that the managers of the Metropolitan Asylums District were proceeding without delay with the consideration of the arrangements which could best be made for the provision for the several classes of children (including the remand children) of whom they were to undertake the care, and the Local Government Board, who had had interviews with the managers on the subject, were rendering such assistance as they could in the matter. But it was impossible at present to state when the accommodation for the children referred to by the hon. Member would be available.—Mr. Pickersgill asked whether the construction of new buildings had begun.—Mr. Chaplin said he did not know whether the managers considered it necessary to have new buildings; he understood they were negotiating for the purchase of existing buildings.

Medical Treatment of Irish Paupers.

Mr. Patrick O'Brien, on behalf of Mr. William Redmond, asked the Chief Secretary to the Lord-Lieutenant of Ireland whether the Tulla board of guardians were surcharged for sending patients who were inmates to Dublin for medical treatment, and whether it was necessary that an inmate should be a certain time, and if so, what length of time, in a union workhouse before being sent to Dublin for medical treatment.—Mr. Gerald Balfour said that the auditor held that the patients whose expenses in Dublin hospitals he surcharged were not *bond fide* inmates of the workhouse, their names having been merely entered on the workhouse books as a preliminary to sending them for special treatment to Dublin. The Act dealing with the matter was the Poor-law Amendment Act of 1862. No particular length of time in a workhouse was specified in the Act as necessary to qualify an inmate for transmission to a special hospital. All that was necessary was that such persons should be *bond fide* inmates at the time they were sent.

Enteric Fever at Agra.

Sir James Fergusson, on behalf of Colonel Kenyon-Slaney, asked the Under Secretary of State for War whether in the 2nd Battalion York and Lancaster Regiment, stationed at Agra, there were, between Feb. 23rd and June 27th, 1897, 77 admissions into hospital from enteric fever, resulting in the deaths of 1 officer and 18 non-commissioned officers and men; whether he could state how many cases of enteric fever were developed in the military hospital by men under treatment for venereal and other diseases; and whether he would institute an inquiry into the causes of this outbreak and into the water-supply.—Mr. Brodrick replied that the returns received from Agra did not extend beyond April 30th. During the months of February, March, and April there appeared to have been 63 admissions for enteric fever and 12 deaths, the great outbreak having occurred in April. There were no returns to show how many cases were developed in hospital in men suffering from other diseases. A special investigation was immediately instituted, with the result that the water supplied by the municipal authorities had been found to be infected with the enteric microbe. Every possible precaution had been taken, and it was stated in the report for April that the epidemic seemed to be abating.

Quarantine at Colombo.

Mr. Chamberlain, in reply to a question by Sir Charles Cayzer, said that his attention had been drawn to the stringent quarantine regulations at Colombo, and he had addressed a despatch to the Governor suggesting modification.

Loss of Life in the Regent's Canal.

Sir M. Bhownaggree asked the Home Secretary if there had been any deaths, and, if so, how many, within the last twelve months by accidental drowning in the East-end portion of the Regent's Canal; and if it was proposed to adopt any special precautions during the winter against accidents likely to result from the unprotected condition of that part of the canal.—Sir M. White Ridley replied: I have not the information which would enable me to answer the first paragraph of the question, but I will call for it and communicate it to the hon. Member. As I informed him on a previous occasion, I have no power to compel the adoption of the necessary precautions, but in accordance with the promise I then gave I brought the matter to the notice of the directors of the company, whose property the canal banks are, and I have been given to understand by them that they do not intend taking any steps in the matter. In these circumstances I propose, after obtaining a special report on the place where the majority of the accidents occur, to consider what further action on my part is desirable and possible in the interest of the public safety.

The Health of the Army in India.

At this sitting of the House during the debate on the Indian Budget several Members referred to the question of venereal disease among the army in India. Mr. James Stuart had intended introducing a resolution to the effect: "That this House disapproves of the repeal of the Cantonment Act Amendment Act of 1895," but the rules of the House prevented him doing so, and he had to content himself with a speech. Some time before Mr. Stuart the House was addressed by Sir Andrew Scoble.—Sir Andrew Scoble said that statistics recently obtained proved most clearly that the freer the hand given to the Government of India in this matter the better it would be for the morality of the British army, for the health of the army, for the people of India, and for the women of India. In 1895, under the pressure of the opinion of this House, an Act was passed restricting the power of the Government of India to make regulations with regard to this form of contagious disease. The Commander-in-Chief, Sir George White, speaking the other day in the Viceroy's Council, supplied the strongest argument for the repeal of that Act, for he said:—

"The statistics of 1895 are in themselves irrefutable proof of the necessity of stronger legislation. In that year, out of 68,331 men in cantonments, the admissions into hospital for venereal diseases were no less than 36,681, or 536·9 per 1000. Of these cases 22,702 were syphilis. The ratio for primary disease has increased 137 per cent. since 1887, and that for secondary disease no less than 188 per cent. in the same period. Secondary syphilis was in 1895 four times more prevalent that it was in 1873."

The Royal College of Physicians of London, who might be taken as an unprejudiced authority, stated in their report:—

"About 13,000 soldiers return to England from India every year, and of these in 1894 over 60 per cent. had suffered from some form of venereal disease. These figures are quoted as showing more forcibly than words can the risk of contamination, not only to the present population of this country, but also to its future generations. Of these men a number die, or, remaining invalids, are more or less incapacitated from earning their own livelihood, and thus become a burden on the rates."

The moral aspects of the question had never been lost sight of by the Government of India. They had carefully desired to give the soldier such employment as might take him away from the gratification of his natural passions, but at the same time a Government which had any regard for its population ought not to hesitate for a moment to apply what it conceived to be the best remedy for putting an end to the existing state of things.

Mr. James Stuart said it would be observed that in the correspondence laid before the House there was no statement of what the Cantonment Act of 1895 provided, and even the best informed organs of public opinion in this country appeared to have fallen into error on the point. For instance, he found THE LANCET saying that "a Bill has been introduced into the Viceregal Legislative Council repealing the Cantonments Act of 1895 and untying the hands of the Indian Government by giving it the same powers in respect of venereal disease that it has in the case of other infectious and contagious disorders." The *Times* went further, and said that the action of the Indian Government simply empowered the bringing of persons affected by the disease under the same regulations as persons affected with cholera, small-pox, &c. Now, the essential part of the Act was to this effect: "Provided that no such rule shall contain any regulation enjoining or permitting any compulsory or periodical examination of any woman by medical officers or others for the purpose of ascertaining whether she is or is not suffering from any venereal disease, or is or is not fit for prostitution, or any regulation for the licensing or special registration of prostitutes or giving legal sanction to the practice of prostitution in any cantonment." What he wished to know was whether the Home Government approved the repeal of this provision. The hon. Member (Sir A. Scoble) argued in favour practically of the re-establishment of the system of regulation which had been so proved and hopeless a failure. He spoke of the increase of disease in the Indian Army since 1873 till now. There had been a great increase, but it took place while the regulations which it was proposed to re-establish existed just as much as since they had been taken out of the way. The Secretary of State had done his best to mitigate the exaggeration which had been indulged in in this connexion, but he had omitted this point, and he had also omitted to state that since the repeal of these regulations disease in the home army had greatly diminished. They could not blow hot and blow cold. They could not say that something that was accompanied by a decrease of disease in this country was the cause of increase of disease in India. Not only so; but they must have regard to the different experiences of stations and of regiments. In one regiment there were four or five times the number of men suffering from the disease that there were in another regiment. He was not going on this occasion to put forward the proposals which he and those who agreed with him on this subject had to offer, but he would say that to deal with this matter effectively they must strike at the vice which was the cause of the disease and endeavour to amend the environment of the soldiers. All he wished to-night was to make it clear that the Indian Government had made a giant stride and had created a new situation which he did not believe was contemplated in the dispatch of the Secretary of State.—Lord George Hamilton said he did not propose to follow the hon. Member at any length. He would say, however, that he adhered to everything in his dispatch. The Indian Government were advised by their legal advisers that if this Act were not repealed the medical officers would not be able to carry on their work under the regulations. These regulations were in strict accordance with his dispatch, and as the Indian Government said they wished to repeal the Act he at once gave his sanction. All that had been done was to give the regulations fair play.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BICKFORD, N. S., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Hospital for Sick Children, Great Ormond-street, Bloomsbury, London.

BULLOCK, W., M.D. Aberd., has been appointed Bacteriologist to the London Hospital, and Lecturer on Bacteriology in the London Hospital Medical School.

CARRUTHERS, E. J. W., M.D., C.M. Edin., has been appointed Medical Officer for the Congleton Sanitary District of the Congleton Union.

DRAFFIN, D. K., L.R.C.P., L.R.C.S. Irel., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Troedyrhiw Sanitary District by the Merthyr Board of Guardians.

HADON, W. F. B., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer for the Second Sanitary District of the Chipping Sodbury Union.

Births, Marriages, and Deaths.

BIRTHS.

BEAUCHAMP.—On Aug. 7th, at Cromwell-road, S.W., the wife of Sydney Beauchamp, M.A., M.B. Cantab., of a son.

CALEY.—On Aug. 5th, at Ealing, the wife of Guthrie Neville Caley, M.D., M.S., of a daughter.

HOOLEY.—On Aug. 4th, at Broxmore, Cobham, Surrey, the wife of Arthur Hooley, M.R.C.S. Eng., L.R.C.P. Edin., of a daughter.

HUBBARD.—On July 31st, at Hemel Hempstead, the wife of Arthur John Hubbard, M.D., of a son.

HUSBAND.—On Aug. 6th, at Crowland, Lincolnshire, the wife of Frank Husband, M.R.C.S., L.R.C.P., of a son.

LACE.—On July 29th, at The Paragon, Bath, the wife of Frederick Lace, F.R.C.S. Eng., of a daughter.

MARRIAGES.

CAPPS—DEACON.—On Aug. 4th, at St. Matthew's, Ealing, Frederick A. Capps, Surgeon R.N., to Helena (Lena), second daughter of Fredk. J. Deacon, of Ealing.

ECCLES—JACKSON.—On Aug. 10th, at the Parish church, Chirk, Arthur Symons Eccles, M.B., of Hertford-street, Mayfair, W., to Annie, eldest daughter of John Jackson, of Caeaugwynion, Chirk, Denbighshire.

GARDINER—DAVIDSON.—On July 26th, at SS. Peter and Paul's, Aldeburgh, John Gardiner, B.A. Oxon., M.R.C.S. Eng., L.R.C.P. Lond., of Oxford, to Florence May, eldest daughter of J. H. Davidson, of Putney.

GILL—BECKLES.—On July 29th, at Christ Church, St. Pancras, Walter Battershell Gill, B.A., M.D. Lond., F.R.C.S. Eng., of Chester-place, Regent's-park, to Jane Gordon, widow of Samuel Husbands Beckles, F.R.S., F.G.S., late of St. Leonards-on-Sea.

KNAGGS—PLAYNE.—On Aug. 10th, at the Parish church, Minchinhampton, by the Rev. C. Hardley, Francis Henry, son of Samuel Knaggs, of Huddersfield, to Martha Isabel, daughter of Charles Playne, J.P., Nailsworth, Glos.

PATERSON—BAKER-GABB.—On Aug. 3rd, at Llanwenarth, Citra, Abergavenny, Donald Rose Paterson, M.D., M.R.C.P., Lecturer on Materia Medica and Pharmacology, University College of South Wales, to Constance Mary, elder daughter of R. Baker-Gabb, The Chain, Abergavenny.

RIGDEN—RIGDEN.—On Aug. 5th, at St. George's, Canterbury, Brian Rigden, M.R.C.S. Eng., to Ellen Morgan Rigden, only daughter of the late John Rigden.

DEATHS.

BARRS.—On Aug. 4th, 1897, at Scarborough, Alice Bywater, aged 34 years, wife of Alfred G. Barrs, M.D., of Leeds, and youngest daughter of Henry Nelson, Esq.

DAVIES.—On Aug. 6th, at Plas Darland, Wrexham, suddenly, Edward Davies, M.D., M.R.C.S., J.P., aged 65 years.

FRICKE.—On July 27th, at Prestwich, Lancashire, Ernest Henry Fricke, M.R.C.S., aged 32 years.

HOLM.—On Aug. 8th, at Putney, John Holm, M.R.C.S. Eng., F.R.C.S. Edin., of Stratford-place, W., aged 57 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

SIR ASTLEY COOPER AND TEMPERANCE.

A CORRESPONDENT wishes to know the reference for the following passage attributed to Sir Astley Cooper: "I never suffer ardent spirits in my house, thinking them evil spirits. Spirits and poisons are synonymous terms."

DISPUTED CHARGES FOR SURGICAL ATTENDANCE.

MR. ALFRED KEBBELL, of Flaxton, lately brought in the County-court, York, an action for the recovery of £25 17*s.* 3*d.* in respect of services rendered to Miss Walton, niece of Mr. Mark Broadley. The case was one of disease of the knee-joint calling for amputation. The patient and her friends objecting to this operation, the joint was opened and drained. Long and constant attention was necessary; medicine and surgical appliances were supplied. In all 110 visits were paid by Mr. Kebbell. No disinterested person can dispute that the charges were very reasonable. The defendant pleaded that he was only a poor farmer making a bare living. He had offered to pay £18 in instalments. The judge said it was the defendant's own fault if he preferred the position of a farmer earning nothing to that of an agricultural labourer on another's farm. Mr. Foster, of York, considered the charges very reasonable indeed. The plaintiff's case was well stated by Mr. H. T. Waddy, instructed by Mr. J. E. Jones. The jury found the plaintiff entitled to the amount claimed, but suggested that Mr. Kebbell should reduce the amount. The plaintiff agreed to take twenty guineas, and judgment was given accordingly.

E. J. Blank, M.D.—The following list will perhaps answer our correspondent's requirements:—"The Spas and Mineral Waters of Europe," by Hermann Weber and F. Parkes Weber (London: Smith, Elder, and Co., 15, Waterloo-place, 1896); a French revised edition of this work is in the press, translated by Dr. Doyon and Dr. Spillmann (Paris: Steinheil). Articles on Climatology, Balneology, and Hydro-therapeutics in Professor Allbutt's "System of Medicine," vol. i., 1896 (London: Macmillan and Co.). Dr. Burney Yeo's "Climate and Health Resorts," third edition (London: Cassell and Co.), is excellent, but may be out of print at present. B. Bradshaw's "Dictionary of Mineral Waters," &c., issued annually (London: Kegan Paul, Trench, Trübner, and Co.), has advantages on account of its long list of places and mention of hotels. "The Climate and Baths of Great Britain" (Published for the Royal Medical and Chirurgical Society of London, 1895). "Ireland: its Health Resorts and Watering-places," by D. Edgar Flinn (Dublin: Fannin and Co.; London: Baillière, Tindall, and Cox, 1895). Karl Grube: "Allgemeine und Specielle Balneotherapie" (Berlin: Hirschwald, 1897); this is a very good general treatise. E. H. Kisch: "Balneo-Therapeutisches Lexikon" (Vienna and Leipzig: Weber und Schwarzenberg, 1897). G. Hayem's "Physical and Natural Therapeutics"; translated from the French by Professor H. A. Hare, of Philadelphia (London and Edinburgh: Pentland, 1895). S. E. Solly's "Handbook of Medical Climatology" (London: J. & A. Churchill, 1897), which has just been issued.

BOOKS ON MATERNITY NURSING.

To the Editors of THE LANCET.

SIRS,—I shall be extremely obliged if you or any of your readers can tell me of any books which would be of use to a lady who is going in for maternity nursing, and enters upon her course at Queen Charlotte Hospital in November next. I am, Sirs, yours faithfully,

Aug. 10th, 1897. ENQUIRER.

Bangor.—We never prescribe or give medical advice. Our correspondent should consult his own medical man.

THE NEW GOLDFIELDS.

THERE does not seem to be any doubt about the presence of a rich auriferous region in Klondike and the Yukon river district. The Canadian Government have decided to demand a royalty on all gold mines in Canadian territory. The rush to the Yukon mines is tremendous. The climate during winter is described as Arctic, and the difficulties of transport and those of food-supply are very great. It is confidently expected that those now proceeding there will have to encounter much hardship, and that, as has been the case on previous occasions of the same kind, there will be a good deal of sickness and mortality. The advice given by those best informed is to wait till the winter is over before starting for these territories. We call attention to the subject because it may be that some of the younger, hardier, and more enterprising members of an overcrowded medical profession are considering whether Klondike may not present them with a field for the practice of their profession and for their enterprise. But in that case it would be well to curb their ardour for the present, to await the receipt of further intelligence, and to arrange for proceeding there in the spring or early summer.

THE F. W. ELLISON FUND.

THE following contributions have been received:—Amount already acknowledged, £47 11*s.*; Dr. W. H. Hutchinson (Cambridge), £1 1*s.*; A Friend (Godalming), 10*s.*; Dr. Joseph Kidd (London), £5.

FISCAL METHODS IN FRANCE.

AN extraordinary, but apparently authentic, anecdote illustrative of Parisian fiscal methods is narrated in the *Éclair*, a physician attached to one of the most important and best known hospitals in Paris being credibly reported as the authority for the following statement: "I am a medical man practising and residing at No. x in Blank-street. I have no other domicile, a fact well known to all my neighbours, and I pay with the utmost regularity all legitimate contributions to the public exchequer. Now the Administration, dissatisfied with its just dues, claims to have received positive information that I do not sleep at home, and I have in consequence been called upon to disburse a formidable sum on account of taxes for the irregular quarters I am credited with. How this amount was arrived at it would be difficult to say, but very likely the highest possible rate was selected to begin with. In reply to any remonstrances I was politely informed that all practitioners are required to pay, not only ordinary taxes, but also professional fees for each dwelling, near or remote, of which they habitually make use. For some time I tried to comfort myself with the thought that this was an official joke and would soon blow over, but the other day a sheriff's officer made his appearance at my real house for the purpose of seizing my effects, and unless I consent to be mulcted for the other fictitious abode they will be sold."

L.R.C.P. would be glad if some brother practitioner could recommend him an asylum within thirty miles of London for a lady patient. The husband is a professional man with only a small income, and could not afford more than 35*s.* per week inclusive. St. Luke's is objected to, and Bethlem would not receive her as the symptoms are of more than twelve months' duration.

"WHAT'S SAUCH FOR THE GOOSH, &c."

To the Editors of THE LANCET.

SIRS,—While admitting that the above old adage has many useful applications in the ordinary affairs of life, I think it singularly inappropriate when applied to the terms upon which the present medical staff of the Carlisle Infirmary hold office. What may be good for the goose may be a bad thing for the gosling; and if the governors at this stage of the history of the infirmary insist upon its medical staff possessing a piquancy, this qualification ought to be imparted with discrimination and fairness all round. When my friend, to whom you refer in your comment as the sauced goose, was told by the infirmary committee that henceforth he must cease laying a portion of his golden eggs, he readily acquiesced, conscious, no doubt, that the loss would be small, and from the fact of his appointment being practically for life in future years a golden opportunity would be afforded of increased oviparation. On the other hand, the gander to whom you give such kind fatherly advice holds office only for seven years, at the end of which time he will receive notice to quit the precincts of the infirmary and search for pastures new. The old statute of the infirmary referred to in your remarks originally made for the honorary medical and surgical staff, becomes bad in principle and worse in practice when applied to the honorary assistant staff. It is well known that one local man eminently qualified for the post of honorary assistant physician has been precluded from applying for the post in case of being asked by the committee to make a sacrifice which no medical man would ever think of submitting to unless he was overburdened with superfluous wealth. It seems somewhat hard that this old and practically obsolete statute of the infirmary, which was considered to be of so little importance that for many years it was totally disregarded, should now be made to apply to the honorary assistant staff. As the rule exists it is clearly the duty of the committee to enforce it, but the sooner the statute is altered the better for the future aspirants for the honorary assistant posts at the infirmary.

I am, Sirs, yours truly,
HONORARY ASSISTANT SURGEON.

Cumberland Infirmary, Aug. 9th, 1897.

Scorbutus.—There is no recent treatise on the subject, but there are excellent articles on it in Russell Reynolds' "System of Medicine," in Ziemssen's Cyclopædia, in vol. vii. of Dr. T. L. Stedman's "Twentieth Century Practice," and in various other works on practice of medicine. The classical authority is Dr. James Lind's "Treatise on the Scurvy," published in 1754.

DANGER TO THE EYES DURING ELECTRIC WELDING.

A COMMUNICATION has reached us written in blue pencil and headed "Danger to the Eyes during Electric Welding, Boring, and other Engineering Operations." It refers to two cases of electric light blindness occurring on H.M.S. *Mars*, and published in THE LANCET of July 24th. As the letter is obviously incomplete, and bears neither the address nor the name of the writer, we cannot insert it, but if he should see this notice we should be obliged if he would supply the deficiencies mentioned.—ED. L.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Why do not the "Incorporated Medical Societies" act as does the "Incorporated Law Society," *vide* paragraph at the top of the page, and if they have not power to do so, why do they not get it?

I am, Sirs, yours truly,
Aug. 11th, 1897. A DISGUSTED M.R.C.S. OF MAY, 1831.

We have received the above from a correspondent. The "paragraph at the top of the page" is a newspaper cutting, which runs as follows:—

"Applications on behalf of the Incorporated Law Society were made in the Queen's Bench Division, before Mr. Justice Lawrance and Mr. Justice Collins, with regard to seven solicitors, and in each case the name of the solicitor complained of was struck off the rolls."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. THE LANCET.

LONDON: SATURDAY, AUGUST 21, 1897.

ADDRESS TO STUDENTS.

WITH the sanguine hopes which seem to be inseparable from youth several hundreds of young men will in October commence the study of medicine. Year by year the examinations have grown in extent and difficulty, the length of the curriculum has been increased, the percentage of failures has risen, yet the entries at the medical schools show but little signs of diminution. To those who propose to enter a medical school we would urge that it is only after careful consideration that anyone should think of becoming a medical student. Five years of study are required—a large section out of most lives; the intellectual capacity needed is far greater than would have sufficed fifty years ago; the lengthening of the course of study has increased the pecuniary outlay; and, lastly, the physical strain of these five years is by no means small, and only too many "faint by the way." It has recently been suggested that a physical examination should precede the commencement of medical study, that a certain height and chest measurement should be required of all medical aspirants! This is going too far, for such a rule would have excluded many who have been brilliant ornaments of their profession; but it is undeniable that the strain is great, and when qualified the medical man will find that in a busy practice night work and long hours will make the strain greater still. A good constitution, therefore, is invaluable to every medical student.

What should be the mental equipment of a young man commencing the study of medicine? It cannot be too good, for not only can the man who has already studied much all the more easily study more, but a good preliminary mental training is of value in many ways. The student who has scraped through his preliminary examination with the minimum of knowledge will often encounter unexpected difficulties where the man of wider general learning will find none. Even a knowledge of Latin and Greek, which it is now so much the custom to despise, is of value, apart from the effect it has in mental training, in supplying meanings to lengthy technical terms, where the untrained eye sees only a crude concourse of meaningless syllables. The subject of the preliminary education which is desirable naturally leads to the question of the entrance examination in general knowledge. Except in the case of those who are proceeding to the older universities the matriculation examination of the University of London offers the greatest advantages; it is accepted by most of the examining bodies, and, in addition, it affords the student an opportunity of proceeding later to the examinations for the degrees of the University of London, should he be so inclined. It is certainly somewhat more difficult than some of the other entrance examinations, but the difference is not so great as it was.

Having successfully encountered the difficulties of the entrance examination, the question of what hospital should be chosen arises. The numerous excellent medical schools in the provinces which have arisen during the past few years are as well-equipped and arranged as any London school, and the men they turn out are as well trained as those from London, but the clinical facilities of the metropolis are so great that every student would do well to spend at least a part of his hospital course in London. The medical schools of London are numerous, and into the choice of a school many considerations will enter. As a rule, if, as is so often the case, the student is the son of a medical man, he will probably go to the hospital where his father was educated. As to whether a large or a small school is to be preferred, it is difficult to give a definite answer. Each has its advantages and disadvantages; the quality of the teaching necessarily varies according to the abilities of the individual members of the teaching staff, and therefore will depend upon them rather than on the particular school.

Having chosen his medical school, the student sees before him five years of hard work before the goal of qualification can be reached. "*Nil sine magno vita labore dedit mortalibus.*" If the five years are well spent the training which the student has undergone will have fitted him to practise his profession with benefit to his patients and with credit to himself. If the five years are ill-spent he may utterly fail in obtaining any qualification, and may have to fill the very undesirable *rôle* of an unqualified assistant (always provided that the General Medical Council does not entirely prohibit the employment of unqualified assistants), "full curriculum, sine diploma," or should he ultimately obtain a qualification his practice can only be unsatisfactory to others and to himself.

It is rather the custom nowadays to decry lectures; and though, perhaps, in these days of excellent text-books lectures are not of such pre-eminent importance as they once were, yet it is highly desirable that the student should attend all the lectures belonging to the course and attend them diligently, for there is a vitality in the knowledge obtained from a living teacher which cannot be got from even the best text-books. Note-taking has by some been unduly praised, and by others to an equal extent it has been unduly blamed. Anything like verbatim note taking can only serve to distract the student's attention from the substance of the lecture, and the notes will be too voluminous for use; it is quite unnecessary; but note-taking to a reasonable extent not merely offers no hindrance to due attention being paid to the lecture, but materially assists the student is listening attentively to all that is said. The value of the notes taken will vary greatly, but in many cases they will serve as text-books for all ordinary examinations. There can be no doubt that the student will find a knowledge of shorthand to be of very great value.

Practical work at the present time forms so large a part of the student's course that the importance attached to it is obvious. In the present great increase in practical work we see the chief difference between the methods of instruction in use now and those employed in former days. An object seen is much more easily remembered than one which has only been read of, and in practical work also habits of

Digitized by Google

accuracy in observation are formed. Accuracy and thoroughness are of the chief importance in all the work a student has to do. Without accuracy knowledge is almost worthless, for it cannot be depended upon, and without thoroughness what has been learned cannot be trusted; one fact well and thoroughly learned is of more value than a dozen facts which have been learned so superficially and so imperfectly that they cannot be easily and accurately recalled.

The whole course of medical study after the passing of the preliminary examination naturally resolves itself into three parts. The first part includes the preliminary science work which has now been adopted by all examining bodies; the sciences taught are chemistry, physics, and biology. In some cases the examination in biology is so superficial that the amount of knowledge required can be of no real use to the student, but in other cases, as at the preliminary scientific examination of the University of London, the examination forms a very useful introduction to the study of the more technical subjects. The second stage includes anatomy and physiology, and on the careful study of these two subjects depends much of the success of the student when he shall come to the study of medicine and surgery, for if the anatomy and physiology have been only superficially learned, endless difficulties will meet the student later. Especially is this the case with anatomy; it is the very foundation on which medicine and surgery are built, and, moreover, it always forms a part of the examination in surgery. Many attempt to learn anatomy from books, but it can only end in failure. What is so learned is quickly forgotten; there is but one satisfactory way of learning anatomy, and that is by dissection.

Until the examination in anatomy and physiology has been passed no hospital work should be done; the work in which the student is engaged is quite sufficient to occupy all his time, and clinical work carried on at the same time would only distract him.

In the third stage come the "final" subjects—Medicine, Surgery, and Midwifery. Most students prefer these subjects to those which precede them, and, indeed, all will allow that there is naturally a greater interest in them, as they will occupy the student in his after life.

We now have to speak of examinations; they are an evil, but a necessary evil, as in no other way can a student's fitness to practise be ascertained. It is of very great importance that the amount of knowledge required for any examination be correctly estimated, for if this is not done a student may fail at an examination, not because of want of diligence, not because of deficiency in ability, but because he has wrongly estimated the quantity or quality of the knowledge required to satisfy the examiners. It is therefore very desirable that the student should not take too narrow a view of any examination, that he should not confine himself necessarily to a single text-book, that he should not refuse to study any particular part of a subject, merely because it is not required at the examination for which he is preparing, for the examination is not everything; the real object of study is to fit him for the practice of his profession, and therefore everything that will render him a more capable physician or surgeon is of value. But it is almost equally important that the student should not fall into the opposite error, and read so much that he has not time to complete all the work required for the examination he has to pass. He must be "just before he is generous." There is another error against which it is necessary to guard; it frequently happens that one subject or part of a subject is more to the candidate's liking than another, and so one subject is diligently studied and the other is neglected. The time at the student's disposal is very limited, the number of subjects which have to be studied is great, and it is necessary to arrange carefully the time devoted to each in order to fit them all in. If the student has regularly attended the lectures and performed the practical work arranged for his examination he should be ready for that examination at the usual time and should pass. As an examination approaches there are few students who do not feel some apprehensions of failure, and the idea of putting off the evil day presents itself to many. It is a very dangerous practice to postpone entering for an examination, as it is only too easily repeated when the next time comes, and thus the whole course is lengthened unnecessarily. Of course, there are unavoidable causes, such as illness, which may necessitate deferring an examination; but with these cases we are not dealing. If the student has worked well he should enter at the appointed time.

We have already spoken of the importance of good physical health to a student at the commencement of his career, but it is equally necessary that he should not allow his health to fail from over-devotion to his studies, and it is still more important that those who at the beginning of their course are in weak health should use all available means to fortify their bodies for the strain which they will have to undergo. Every student should have some form of recreation, and at the present time it cannot be said that there is any lack of opportunities for physical exercise; every medical school has attached to it cricket, football, cycling, and athletic clubs; many of them have extensive grounds a few miles out of London. There can be no excuse for a student who falls ill from want of exercise. The best mental results will be obtained by paying due attention to the physical needs of the body; a healthy active mind cannot long exist in an enfeebled frame. Especially is a healthy body necessary in those who are doing clinical work; hospital sore-throat and kindred diseases only occur in those who are "run down." Many students need the warning we have given, but probably there are many others who should take care that physical exercise does not get more than its share of attention. Cricket and cycling especially are so engrossing that much valuable time may easily be wasted. It is impossible to lay down fixed rules; some men undoubtedly require more exercise than others in order to keep in good health; the amount necessary must be decided conscientiously by every man for himself. Let neither the mind nor the body be neglected, but let each have its due share of attention. Every year, also, the student should take at least a month's holiday, and though an hour's daily reading during his vacation will do him no harm, yet he should endeavour to get as much good as possible out of the entire change of scene and habits of life.

When the five years have come to an end, and the quondam student has obtained the coveted diploma, let him not think that he possesses all the knowledge he will need; every true medical man is a student all his life. Many men

Digitized by Google

never realise how little they know of medicine and surgery until the examiners have certified that they are capable of practising. After qualification every man who can possibly do so should obtain a resident post, if not in his own hospital, in one of the numerous hospitals in or out of London to which no medical school is attached. In such a post he will for the first time have real responsibility, with the advantage of the experience and knowledge of his chief in any difficulty.

Later still the paths of medical practice diverge; if a man decides to undertake general practice he will have to buy a practice or a partnership or he must make a practice. Which of these methods he will choose will depend greatly on his pecuniary resources, and in each there are difficulties and dangers of which we have not space to write now. Should he intend to undertake consulting work there will be many years before him in which he must do an immense amount of work for which he will receive no pay, and even after many years of waiting he may never succeed in earning sufficient to pay his expenses. Truly the prizes are great, but the blanks are much more numerous.

Every medical man should endeavour to keep up with the onward march of knowledge; the facilities afforded at present are very great; in addition to the professional journals, medical lending libraries put the latest knowledge within the reach of the country practitioner at a very small cost; and the post-graduate classes which have recently been established are of incalculable value to those who have allowed their knowledge to fall a little behind the times.

In conclusion we offer a hearty God-speed to those who are about to enter on the work which alone can render them fit, and enable them to become legally qualified, for the practice of the profession of medicine.

THE COST OF MEDICAL EDUCATION.

WE have for several years been in the habit of placing before our readers an estimate of the cost of medical education in order that those interested in arriving at the whole amount of this expense—which is by no means limited to such obviously necessary payments as fees, board, and lodging—may have some trustworthy materials before them on which to found a decision about joining a medical school. We obtained our original information from personal communications as answers to a schedule of questions placed by the aid of the deans and registrars of the various medical schools in the hands of a certain number of selected students, who were requested to furnish in the form of replies the data from which a general statement could be prepared for the guidance of others. Although the habits of the individual students necessarily had a great, even a preponderating, effect upon the replies, the returns were sufficiently numerous to yield averages, and it was easy to see that the average man spent more money in the metropolitan centres than in the provinces, and that the standard of living and the cost of maintaining a given standard varied from place to place. The most complete statement that we received came from a provincial student, whose great economy in the matter of personal expenses could only be looked upon as an example to distinctly follow. It would have been unfair to expect that every student could live so frugally as to support himself and pay for rent and food (ten months), clothes, washing, recreation, fees, and even "incidental" and "unaccounted" expenses of the the small annual sum of £65. But these headings will serve as a plan upon which we can discuss the subject generally—premising that only general information can be given that is worth anything, as a medical student as much as any other young man can make his expenses as large as he wishes, while he can only reduce them to the point that is permitted by the circumstances under which he is studying.

The cost of *rent* is the first item to be considered, and naturally enough is a charge which varies greatly with the locality. A student who occupies rooms in desirable quarters of London will pay from £2 to £3 a week on this account alone, whilst in many large provincial centres lodgings are almost as expensive as they are in London. We may take it that a student's rent for furnished apartments ought not to amount to more than one-quarter of the sum that he can fairly count upon receiving as income. If his parents can allow him £150 per annum (a large sum and one that is beyond the power of the parents of many medical students to set aside for one child) his rent should not be more than £1 a week. We are calculating that he will reside at the particular centre of education for about ten months during the year. In London it is not always easy to live near the hospital and obtain lodgings for much less than £1 a week, so that if a student can only expect £2 a week or £6 a month from his parents he is absolutely compelled to spend an imprudent proportion of his income in rent. Clearly none of this applies either to the students who live with their parents or those who are studying at a university for an arts degree concurrently. Nothing more definite on this subject can be said than that a careful man can live as a medical student on £80 per annum if he does not spend more than 10*s.* a week on his lodgings; but he will not always find it easy to obtain the lodgings, and every shilling above this weekly sum will make it very hard indeed for him to make both ends meet. It is true that we heard this year of one medical student who sold the window at the top of the market in the boom of jubilee seats and cleared thereby several times his annual rent, but it would not be prudent for others to expect such good fortune.

Referring to other centres, the rent of lodgings in Edinburgh is considerably less than in London, but in Dublin it is about the same as in the English metropolis. In Edinburgh there is a sort of residential club known as University Hall which affords facilities of social intercourse and mutual aid, as, for example, in the lending of books, which is practised systematically among the resident students. In addition to these amenities, the institution secures them lodgings at a very moderate monthly rent. Glasgow lodgings again run at about the same level, whilst in Birmingham rent is cheaper still. The cheapest district of which we have any full information is Aberdeen, where both in the matter of rent and of food we have heard of an economy that is altogether exceptional, 3*s.* 6*d.* a week in summer and 4*s.* 6*d.* in winter, the additional shilling representing the cost of fuel to cope with the Scottish winter. In towns like Cork and Leeds the average rises above this limit, but 15*s.* a week

Digitized by Google

is a somewhat high charge. In the Irish provincial towns the rent of rooms is very low, 5*s.* and 6*s.* being by no means below the average. A somewhat higher rent is asked, but still ranging about 10*s.* a week, in English provincial towns, such as Stockton, or Rugby, or Devonport; but residence in these involves constant railway travelling, and would hardly be adapted for the purposes of a student's career, unless some special considerations influenced the decision with which fine questions of comparative expense would not come into competition. The lodging accommodation afforded by residential colleges, hospitals, and the like institutions should be mentioned. But concerning these a word may suffice. The advantages of residence in a college are manifold, but they are chiefly of the intellectual and social kind. The cost is not less than that of private lodgings thriftily selected. There may also be in some instances impatience on the part of the student of the control imposed by the regulations, which are necessarily devised for the orderly conduct of such institutions. Nevertheless, the select society, and even the inevitable restraint, of such institutions are of great service, especially to young students, who have reason to dread nothing more than solitude and an irresponsible control of any considerable proportion of their own time. On the other hand, the cost of board and lodging in such institutions is not greater than the average cost of the same accommodation in private lodgings in their neighbourhood. A plan that involves no inordinate expense is to place a student in the house of a medical practitioner in the neighbourhood of the school which he is attending. It will be found that when the educational facilities thus placed in his way are taken into account, in addition to the mere commercial value of his board and lodging, the arrangement is usually a very economical one. The opportunities for doing this are, of course, not unlimited, but they are sufficiently numerous to merit mention here. A word of warning must be added. Every man who is willing to receive a student into his house and who offers advantages in the way of private tuition may not be capable of carrying out his promises. The modern curriculum is a severe one, and the preliminary scientific work is more severe than it was a generation or even a decade back. We recommend that the advice of the dean of the school be asked before any bargain is entered upon.

Passing to the next heading, that of *food*, we may observe that here again nothing can be said precisely, but we can indicate the minimum sum that can be spent, and variation from this sum must be dictated by the student's purse. The prevalence of high prices or of low prices, as the case may be, affects such figures very little, and we may say that £30 is, we consider, in London the least sum that will meet necessary expenditure on good food. There will be no real economy for student or parent in the attempt to save in this item. We again refer only to ten months in the year.

Lastly, with regard to *fees*, the composition fee which is published by the various schools, and is in a sense a comprehensive charge, may easily be supposed to be more comprehensive than it is. A glance at our tables will show exactly how it is arrived at and what it covers. Broadly, it may be said to include all the professorial fees; but it does not include *books*—that is a matter of course. Equally it does not include *instruments*, and these two items together cannot be fairly written down at less than £8 a year in an ordinary case. Many circumstances may occur to falsify this estimate. A successful student may largely supply himself with books by prize-winning, or access to a suitable library may minimise his personal requirements in this respect. With instruments, bones, parts for dissection, and the like, the case is somewhat different, and the expenditure under these heads can only be avoided at the expense of the student's education. A niggard hand in such matters makes therefore a grievous mistake, and this should be clearly appreciated at first, otherwise the temptation to undue parsimony will be supported by a grudging mind. Another item which is for very good reason omitted from the composition payment is the *charge for examination fees*. The reason of this will be at once apparent if it is only considered that the teaching bodies and the examining bodies are distinct, and that whereas the composition fee represents a sum payable to institutions of the former class, the examination fees are receivable by institutions exercising the examining function. It will be hard to quarrel with an arrangement which is justified by the importance of paying the fee to the right person. Less obvious, but of the same kind, is the explanation of the circumstance that *tutorial fees* are not included in the composition. Many students pass through their curriculum by the aid of lectures and professorial instruction only. This is very possible when only pass examinations are attempted; but for competitive examinations additional instruction is generally an indispensable preparatory. Such additional instruction must of course be paid for, but its occasional character prohibits its inclusion with the indispensable items in the comprehensive payment.

To sum up, we have this position: The minimum sum that a student must be prepared to spend in London during a year on board and lodging is £60, though £50 will cover his expenditure in these directions in other centres, and less if he is careful. He can save 20 per cent. of this expenditure by living with a fellow-student to their mutual benefit. He must be prepared to spend £10 more at least in books, or instruments, or both. He will be almost the exception if he does not incur one or two extra liabilities in the way of special tuition during his five years' career. He will require another £10 a year as pocket money, and to these figures must be added his fees and the price of his clothes. We do not think that in London any young man should be asked to attempt to maintain himself entirely and pay all necessary fees and expenses of education as well upon a less sum than £100 a year. That many receive less and, to their infinite credit, make it suffice and crown the self-denial of their youth with a success that is sweetened by the struggle to obtain it is undeniable; but many more of their fellow-students receive larger allowances and find them inadequate. Upon individual instances, with their innumerable reasons for special treatment, we do not attempt to dwell, and we desire our readers to remember that, roughly speaking, the figures which we now give for London are a little, perhaps 15 per cent., in excess of those that with the practice of economy would be found to apply to the provinces, Scotland, and Ireland.

Our advice is very general and is as follows: If a student cannot command personally or by allowance from his parents £100 per annum, and look to receiving it regularly for at least four out of the five years of his curriculum, we consider that he is rash in these exacting days to embark upon our profession. These are almost identical with words that we have previously used in treating this topic, but no alteration in prices or conditions makes them less true.

THE FUTURE OF PHOTOGRAPHY IN ITS APPLICATION TO MEDICINE.

PHOTOGRAPHY has come so rapidly forward of recent years as an aid to our senses, and in materially increasing the value of our observations, that no apology is needed for pointing out briefly the advantages which the practical study of the art would afford the medical student. The extremely sensitive photographic film only illustrates, after all, how dull is the perceptive power of the eye, and how far short of perfection it falls, considered in the light of an optical instrument. In recommending the student to practise photography we do not do so with any wish to burden him with another subject in his already crowded curriculum. We rather enjoin him to acquire a practical knowledge of photography because it tends to sharpen his powers of observation, to lead him to make faithful records, and to cultivate in him the artistic method. Indeed, we suggest it as a pleasant, instructive, and recreative pursuit, and in these days of dry and rapid plates and of cheap yet good apparatus there is nothing so simple as taking a photograph and taking it well. Then, again, the student's recently-acquired or freshened knowledge of chemistry will in no small measure enable him to obtain good results. At most medical schools now dark rooms are provided and other facilities afforded for taking photographs, since a knowledge of practical photography is found to be extremely useful in the dissecting-room, in the post-mortem room, in the ward, and in the operating theatre, while the capacity to take a micro-photograph is essential in the practical study of bacteriology and physiology. Even in these applications photography may be pursued as a hobby, but what a useful hobby! It is but a simple step from the photograph to the block picture used for illustrating published communications, and in describing cases of surgical or of general medical interest photography again and again proves an invaluable aid.

We go a step further than this because the extreme sensitiveness of the photographic film has more recently laid bare certain phenomena which otherwise would probably to this date have remained unobserved. The phenomena we refer to are not interesting merely as phenomena, but, as is now well known, they have led to a remarkable application of photography to the diagnosis of disease and to the discernment with more or less certainty of hidden anatomical abnormalities or even of pathological conditions. We refer to the "x" rays. In addition to a good sensitive plate, the student requires for this work a good induction coil and a vacuum tube, but the camera is no longer necessary. Indeed, for many purposes the sensitive plate may be dispensed with, since the rays may be made visible by means of the fluorescent screen. Examples of photographs showing the internal structure of the body, of the organs, and the bones, or of hidden foreign bodies are now too familiar to need any further description. The discovery has brought to light one extremely important fact—namely, that there exist vibrations which are so rapid as to pass easily through what are otherwise opaque substances, and yet which fail to create an impression upon the optic nerve. But the sensitive plate reveals them just as it records an infinitely greater number of stars than the eye is enabled by the best telescope to see. The demonstrated existence of such highly attenuated matter must have a profound influence upon our preconceived ideas of the nature of that mysterious thing—the elementary substance, or matter. Further, it has recently been shown that light or at any rate vibrations similar to it are emitted by almost all substances. Perhaps the most remarkable example of this kind is afforded by uranium and its salts, which emit a peculiar kind of light which is dark to the eye, but which very distinctly affects the photographic plate. And, strangest thing of all, this property appears to be inexhaustible. Moreover, the radiations so obtained appear to be like the "x" rays, able to permeate such ordinary opaque substances as black paper, celluloid, &c.

Another most promising development in photography, and one which will probably have an important bearing on medicine, is the recently announced discovery of a process by which the objects photographed may be displayed in all the variety of their natural colours. In this process the photograph is taken in the ordinary way and a print obtained. This is then immersed in a certain solution containing apparently a great number of chemical salts. The nature of these salts and the quantity employed are at present a secret. The photographic print when placed in this mixture appears to exert a selective action, and the colouring matters applied to it have a certain tendency to attach themselves to those portions of the print which would be of a similar colour had the image been reproduced in natural colours. Thus, the colouring matters, when applied in succession, so combine or react on each other as to reproduce approximately the tones or tints of the original. The process is not altogether a mechanical one, but requires some amount of skill, chiefly in judging when the intensity of the tones is sufficient in order that the result may be artistic and true. It is quite evident that when the particulars of this process are made known an additional means of great importance and value will be at the disposal of surgeons and physicians for making more exact pictorial records of surgical and anatomical cases and morbid specimens.

We are sure we have indicated sufficiently what profit and instruction may be gained from a knowledge of practical photography and its application, and we are confident that the medical student will not waste or burden his time by taking up this art, but, on the contrary, will find that there is much therein that is profitable and recreative.
